The area \(A\) of a region \(R\) in the image with the gray values \(g(r,c)\) is defined as

\[
A = \sum_{(r,c) \in R} g(r,c).
\]

This means that the area is defined by the volume of the gray value function \(g(r,c)\). The center of gravity is defined by the first two normalized moments of the gray values \(g(r,c)\), i.e., by \((m_{1,0}, m_{0,1})\), where

\[
m_{p,q} = \frac{1}{A} \sum_{(r,c) \in R} r^p c^q g(r,c).
\]

Note, that in the case where the Area is zero the row and column coordinates of the center of gravity are also set to zero.

**Attention**

Note that the operator `area_center_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`. `area_center_gray` can be executed on OpenCL devices if the device supports the cl_khr_fp64 and cl_khr_int64_base_atomics OpenCL extensions.
15.6. FEATURES

Parameters

▷ **Regions** (input_object) ............................................................... region(-array) 〜 object
  Region(s) to be examined.

▷ **Image** (input_object) ........................................................... singlechannelimage 〜 object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  Gray value image.

▷ **Area** (output_control) ............................................................. real(-array) 〜 real
  Gray value volume of the region.

▷ **Row** (output_control) ............................................................. point.y(-array) 〜 real
  Row coordinate of the gray value center of gravity.

▷ **Column** (output_control) ........................................................ point.x(-array) 〜 real
  Column coordinate of the gray value center of gravity.

Result

*area_center_gray* returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system(:'no_object_result',<Result>: )`. If necessary, an exception is raised.

Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Alternatives

**area_center**

**area_center_xld, elliptic_axis_gray**

Module

**cooc_feature_image** ( Regions, Image : : LdGray, Direction : Energy, Correlation, Homogeneity, Contrast )

Calculate a co-occurrence matrix and derive gray value features thereof.

The call of `cooc_feature_image` corresponds to the consecutive execution of the operators `gen_cooc_matrix` and `cooc_feature_matrix`. If several direction matrices of the co-occurrence matrix are to be evaluated consecutively, it is more efficient to generate the matrix via `gen_cooc_matrix` and then call the operator `cooc_feature_matrix` for the resulting matrix. The parameter `Direction` transfers the direction of the neighborhood in angle or 'mean'. In the case of 'mean' the mean value is calculated in all four directions.

Attention

Note that the operator `cooc_feature_image` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

▷ **Regions** (input_object) ............................................................... region(-array) 〜 object
  Region to be examined.

▷ **Image** (input_object) ........................................................... singlechannelimage 〜 object : byte
  Corresponding gray values.
The operator \texttt{cooc\_feature\_image} returns the value 2 (H\_MSG\_TRUE) if an image with defined gray values ('byte') is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator \texttt{set\_system} (::'no\_object\_result',<Result>:), the behavior in case of empty region is set via \texttt{set\_system} (::'empty\_region\_result',<Result>:). If necessary an exception is raised.

\textbf{Parallelization}

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

\textbf{Possible Predecessors}
\begin{itemize}

\begin{verbatim}
cooc_feature_matrix ( CoocMatrix : : : Energy, Correlation,
                     Homogeneity, Contrast )
\end{verbatim}

Calculate gray value features from a co-occurrence matrix.

The operator calculates from a co-occurrence matrix (\texttt{CoocMatrix}) the energy (\texttt{Energy}), correlation (\texttt{Correlation}), local homogeneity (\texttt{Homogeneity}) and contrast (\texttt{Contrast}).

The operator \texttt{cooc\_feature\_matrix} calculates the gray value features from the part of the input matrix generated by \texttt{gen\_cooc\_matrix} corresponding to the direction matrix indicated by the parameters \texttt{LdGray} and \texttt{Direction} according to the following formulae:

\begin{align*}
\text{Energy} & = \sum_{i,j=0}^{\text{width}} c_{ij}^2 \\
\text{(Measure for image homogeneity)}
\end{align*}

Correlation:
Correlation = \[ \sum_{i,j=0}^{\text{width}} (i - u_x)(j - u_y)c_{ij} \]
\[
\frac{s_x s_y}{s_x^2 s_y^2}
\]
(Measure for gray value dependencies)

Local homogeneity:

\[ \text{Homogeneity} = \sum_{i,j=0}^{\text{width}} \frac{1}{1 + (i - j)^2} c_{ij} \]

Contrast:

\[ \text{Contrast} = \sum_{i,j=0}^{\text{width}} (i - j)^2 c_{ij} \]

(Measure for the size of the intensity differences)

where

- \( width \) = Width of CoocMatrix
- \( c_{ij} \) = Entry of co-occurrence matrix
- \( u_x \) = \[ \sum_{i,j=0}^{\text{width}} i \ast c_{ij} \]
- \( u_y \) = \[ \sum_{i,j=0}^{\text{width}} j \ast c_{ij} \]
- \( s_x^2 \) = \[ \sum_{i,j=0}^{\text{width}} (i - u_x)^2 \ast c_{ij} \]
- \( s_y^2 \) = \[ \sum_{i,j=0}^{\text{width}} (i - u_y)^2 \ast c_{ij} \]

**Attention**

The region of the input image is disregarded.

**Parameters**

- CoocMatrix (input_object) .................... singlechannelimage(-array) \( \leadsto \) object : real
- Co-occurrence matrix.
- Energy (output_control) .............................. real \( \leadsto \) real
- Homogeneity of the gray values.
- Correlation (output_control) ...................... real \( \leadsto \) real
- Correlation of gray values.
- Homogeneity (output_control) ...................... real \( \leadsto \) real
- Local homogeneity of gray values.
- Contrast (output_control) ........................... real \( \leadsto \) real
- Gray value contrast.

**Result**

The operator cooc_feature_matrix returns the value 2 (H_MSG_TRUE) if an image with defined gray values is passed and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(\(::\)’no_object_result’,<Result>). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Predecessors**

gen_cooc_matrix

coop_feature_image
See also intensity, min_max_gray, entropy_gray, select_gray

**elliptic_axis_gray** (Regions, Image : : : Ra, Rb, Phi )

Compute the orientation and major axes of a region in a gray value image.

The operator `elliptic_axis_gray` calculates the length of the axes and the orientation of the ellipse having the "same orientation" and the "aspect ratio" as the input region. Several input regions can be passed in `Regions` as tuples. The length of the major axis `Ra` and the minor axis `Rb` as well as the orientation of the major axis with regard to the x-axis (`Phi`) are determined. The angle is returned in radians. The calculation is done analogously to `elliptic_axis`. The only difference is that in `elliptic_axis_gray` the gray value moments are used instead of the region moments. The gray value moments are derived from the input image `Image`. For the definition of the gray value moments, see `area_center_gray`.

Note, that in the case where the gray value area is zero the length of the axes `Ra` and `Rb` as well as the orientation `Phi` are also set to zero.

---

**Attention**

Note that the operator `elliptic_axis_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

**Parameters**

- `Regions` (input_object) region(-array) object Region(s) to be examined.
- `Ra` (output_control) real(-array) real Major axis of the region.
- `Rb` (output_control) real(-array) real Minor axis of the region.
- `Phi` (output_control) angle.rad(-array) real Angle enclosed by the major axis and the x-axis.

**Result**

`elliptic_axis_gray` returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system::('no_object_result',<Result>).` If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Foundation

**HALCON/HDevelop Reference Manual, 2020-5-13**
**entropy_gray** ( Regions, Image : : : Entropy, Anisotropy )

Determine the entropy and anisotropy of images.

The operator `entropy_gray` creates the histogram of relative frequencies of the gray values in the input image and calculates from these frequencies the entropy and the anisotropy coefficient for each region from `Regions` according to the following formulae:

**Entropy:**

$$ Entropy = - \sum_{i=0}^{255} rel[i] \cdot \log_2(rel[i]) $$

**Anisotropy coefficient:**

$$ Anisotropy = \frac{\sum_{i=0}^{k} rel[i] \cdot \log_2(rel[i])}{Entropy} $$

where

- `rel[i]` = Histogram of relative gray value frequencies
- `i` = Gray value of input image (0...255)
- `k` = Smallest possible gray value with $$\sum_{i=0}^{k} rel[i] \geq 0.5$$

**Attention**

Note that the operator `entropy_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

---

**Parameters**

- `Regions` (input_object) : region(-array) \(\sim object\)Regions where the features are to be determined.
- `Image` (input_object) : singlechannelimage \(\sim object : byte\)Gray value image.
- `Entropy` (output_control) : real(-array) \(\sim real\)Information content (entropy) of the gray values.
  - **Assertion:** \(0 <= Entropy \&\& Entropy <= 8\)
- `Anisotropy` (output_control) : real(-array) \(\sim real\)Measure of the symmetry of gray value distribution.

---

**Complexity**

If \(F\) is the area of the region the runtime complexity is \(O(F + 255)\).

---

**Result**

The operator `entropy_gray` returns the value 2 (H_MSG_TRUE) if an image with defined gray values is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system::('no_object_result',<Result>:)`, the behavior in case of empty region is set via `set_system::('empty_region_result',<Result>:)`. If necessary an exception is raised.

**Module**

Foundation
estimate_noise ( Image : : Method, Percent : Sigma )

Estimate the image noise from a single image.

The operator estimate_noise estimates the standard deviation of additive noise within the domain of the image that is passed in Image. The standard deviation is returned in Sigma.

The operator is useful in the following use cases:

- determination of MinContrast for matching,
- determination of the amplitude for edge filters,
- camera evaluation,
- monitoring errors in camera operation (e.g., user overdrives camera gain).

To estimate the noise, one of the following four methods can be selected in Method:

- 'foerstner': If Method is set to 'foerstner', first for each pixel a homogeneity measure is computed based on the first derivatives of the gray values of Image. By thresholding the homogeneity measure one obtains the homogeneous regions in the image. The threshold is computed based on a starting value for the image noise. The starting value is obtained by applying the method 'immerkaer' (see below) in the first step. It is assumed that the gray value fluctuations within the homogeneous regions are solely caused by the image noise. Furthermore it is assumed that the image noise is Gaussian distributed. The average homogeneity measure within the homogeneous regions is then used to calculate a refined estimate for the image noise. The refined estimate leads to a new threshold for the homogeneity. The described process is iterated until the estimated image noise remains constant between two successive iterations. Finally, the standard deviation of the estimated image noise is returned in 'Sigma'.

  Note that in some cases the iteration falsely converges to the value 0. This happens, for example, if the gray value histogram of the input image contains gaps that are caused either by an automatic radiometric scaling of the camera or frame grabber, respectively, or by a manual spreading of the gray values using a scaling factor > 1.

  Also note that the result obtained by this method is independent of the value passed in Percent.

- 'immerkaer': If Method is set to 'immerkaer', first the following filter mask is applied to the input image:

  \[ M = \begin{bmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{bmatrix} \]

  The advantage of this method is that \( M \) is almost insensitive to image structure but only depends on the noise in the image. Assuming a Gaussian distributed noise, its standard deviation is finally obtained as

  \[ 'Sigma' = \sqrt{\frac{\pi}{26N}} \sum_{Image} |Image' \ast M|, \]

  where \( N \) is the number of image pixels to which \( M \) is applied. Note that the result obtained by this method is independent of the value passed in Percent.

- 'least_squares': If Method is set to 'least_squares', the fluctuations of the gray values with respect to a locally fitted gray value plane are used to estimate the image noise. First, a homogeneity measure is computed based on the first derivatives of the gray values of Image. Homogeneous image regions are determined by selecting the Percent percent most homogeneous pixels in the domain of the input image, i.e., pixels with small magnitudes of the first derivatives. For each homogeneous pixel a gray value plane is fitted to its \( 3 \times 3 \) neighborhood. The differences between the gray values within the \( 3 \times 3 \) neighborhood and the locally fitted plane are used to estimate the standard deviation of the noise. Finally, the average standard deviation over all homogeneous pixels is returned in Sigma.

- 'mean': If Method is set to 'mean', the noise estimation is based on the difference between the input image and a noiseless version of the input image. First, a homogeneity measure is computed based on the first derivatives of the gray values of Image. Homogeneous image regions are determined by selecting the Percent percent most homogeneous pixels in the domain of the input image, i.e., pixels with small magnitudes of the first derivatives. A mean filter is applied to the homogeneous image regions in order to eliminate the noise. It is assumed that the difference between the input image and the thus obtained noiseless
version of the image represents the image noise. Finally, the standard deviation of the differences is returned in \( \Sigma \). It should be noted that this method requires large connected homogeneous image regions to be able to reliably estimate the noise.

Note that the methods 'foerstner' and 'immerkaer' assume a Gaussian distribution of the image noise, whereas the methods 'least_squares' and 'mean' can be applied to images with arbitrarily distributed noise. In general, the method 'foerstner' returns the most accurate results while the method 'immerkaer' shows the fastest computation.

If the image noise could not be estimated reliably, the error 3175 is raised. This may happen if the image does not contain enough homogeneous regions, if the image was artificially created, or if the noise is not of Gaussian type. In order to avoid this error, it might be useful in some cases to try one of the following modifications in dependence of the estimation method that is passed in Method:

- Increase the size of the input image domain (useful for all methods).
- Increase the value of the parameter Percent (useful for methods 'least_squares' and 'mean').
- Use the method 'immerkaer', instead of the methods 'foerstner', 'least_squares', or 'mean'. The method 'immerkaer' does not rely on the existence of homogeneous image regions, and hence is almost always applicable.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

### Parameters

- \( \text{Image} \) (input_object) \( \sim \) singlechannelImage(-array) \( \sim \) object : byte / uint2
  - Input image.

- \( \text{Method} \) (input_control) \( \sim \) string
  - Method to estimate the image noise.
  - Default value: 'foerstner'
  - List of values: \( \text{Method} \in \{'foerstner', 'immerkaer', 'least_squares', 'mean'\} \)

- \( \text{Percent} \) (input_control) \( \sim \) number
  - Percentage of used image points.
  - Default value: 20
  - Suggested values: \( \text{Percent} \in \{1, 2, 5, 7, 10, 15, 20, 30, 40, 50\} \)
  - Restriction: \( 0 < \text{Percent} \&\& \text{Percent} \leq 50. \)

- \( \text{Sigma} \) (output_control) \( \sim \) real(-array) \( \sim \) real
  - Standard deviation of the image noise.
  - Assertion: \( \text{Sigma} \geq 0 \)

### Example

```halcon
read_image (Image, 'combine')
estimate_noise (ImageNoise, 'foerstner', 20, SigmaFoerstner)
estimate_noise (ImageNoise, 'immerkaer', 20, SigmaImmerkaer)
estimate_noise (ImageNoise, 'least_squares', 20, SigmaLeastSquares)
estimate_noise (ImageNoise, 'mean', 20, SigmaMean)
```

### Result

If the parameters are valid, the operator estimate_noise returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the image noise could not be estimated reliably, the error 3175 is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

fit_surface_first_order ( Regions, Image : Algorithm, Iterations, ClippingFactor : Alpha, Beta, Gamma )

Calculate gray value moments and approximation by a first order surface (plane).

The operator fit_surface_first_order calculates the gray value moments and the parameters of the approximation of the gray values by a first order surface. The calculation is done by minimizing the distance between the gray values and the surface. A first order surface is described by the following formula:

\[ \text{Image}(r,c) = \text{Alpha}(r - r\_center) + \text{Beta}(c - c\_center) + \text{Gamma} \]

r_center and c_center are the center coordinates of intersection of the input region with the full image domain. By the minimization process the parameters from \text{Alpha} to \text{Gamma} is calculated.

The algorithm used for the fitting can be selected via \text{Algorithm}:

'\text{regression}' Standard 'least squares' line fitting.
'\text{huber}' Weighted 'least squares' fitting, where the impact of outliers is decreased based on the approach of Huber.
'tukey' Weighted 'least squares' fitting, where outliers are ignored based on the approach of Tukey.

The parameter \text{ClippingFactor} (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for \text{ClippingFactor} the more outliers are detected. The detection of outliers is repeated. The parameter \text{Iterations} specifies the number of iterations. In the modus 'regression' this value is ignored.

Attention
Note that the operator fit_surface_first_order only considers the given \text{Regions} and ignores any previously set domain of the input image \text{Image}.

Parameters

\begin{itemize}
  \item \text{Regions} (input_object) \text{region(-array)} \sim \text{object}
    \text{Regions to be checked.}
  \item \text{Image} (input_object) \text{singlechannelimage} \sim \text{byte / uint2 / direction / cyclic / real}
    \text{Corresponding gray values.}
  \item \text{Algorithm} (input_control) \text{string} \sim \text{string}
    \text{Algorithm for the fitting. Default value: 'regression'}
    \text{List of values: Algorithm \in [‘regression’, ‘huber’, ‘tukey’]}
\end{itemize}
**Features**

- **Iterations** (input_control) ............................................................ integer → integer
  Maximum number of iterations (unused for ‘regression’).
  Default value: 5
  Restriction: Iterations >= 0

- **ClippingFactor** (input_control) .................................................. real → real
  Clipping factor for the elimination of outliers.
  Default value: 2.0
  List of values: ClippingFactor ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
  Restriction: ClippingFactor > 0

- **Alpha** (output_control) ......................................................... real(-array) → real
  Parameter Alpha of the approximating surface.

- **Beta** (output_control) ............................................................ real(-array) → real
  Parameter Beta of the approximating surface.

- **Gamma** (output_control) .......................................................... real(-array) → real
  Parameter Gamma of the approximating surface.

Result

The operator `fit_surface_first_order` returns the value 2 (H_MSG_TRUE) if an image with the defined gray values (’byte’) is entered and the parameters are correct. If necessary an exception is raised.

Parallellization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Possible Successors

- `gen_image_surface_first_order`
  
See also

- `moments_gray_plane`, `fit_surface_second_order`

Module

**fit_surface_second_order** ( Regions, Image : : Algorithm,
  Iterations, ClippingFactor : Alpha, Beta, Gamma, Delta, Epsilon,
  Zeta )

Calculate gray value moments and approximation by a second order surface.

The operator `fit_surface_second_order` calculates the gray value moments and the parameters of the approximation of the gray values by a second order surface. The calculation is done by minimizing the distance between the gray values and the surface. A second order surface is described by the following formula:

\[
\text{Image}(r,c) = \alpha(r-r_{\text{center}})^2 + \beta(c-c_{\text{center}})^2 + \gamma(r-r_{\text{center}})(c-c_{\text{center}}) + \delta(r-r_{\text{center}}) + \epsilon(c-c_{\text{center}}) + \zeta
\]

\(r_{\text{center}}\) and \(c_{\text{center}}\) are the center coordinates of the intersection of the input region with the full image domain. By the minimization process the parameters from \(\alpha\) to \(\zeta\) is calculated.

The algorithm used for the fitting can be selected via `Algorithm`:

HALCON 20.05.0.0
The parameter `ClippingFactor` (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for `ClippingFactor` the more outliers are detected. The detection of outliers is repeated. The parameter `Iterations` specifies the number of iterations. In the modus `regression` this value is ignored.

Attention

Note that the operator `fit_surface_second_order` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

---

### Parameters

- **Regions** (input_object)  
  Region-array  
  Regions to be checked.
- **Image** (input_object)  
  Singlechannelimage  
  Corresponding gray values.
- **Algorithm** (input_control)  
  String  
  Algorithm for the fitting.
  
  **Default value:** 'regression'
  
  **List of values:** `Algorithm ∈ { 'regression', 'tukey', 'huber' }`
- **Iterations** (input_control)  
  Integer  
  Maximum number of iterations (unused for 'regression').
  
  **Default value:** 5
  
  **Restriction:** Iterations >= 0

### Possible Successors

- `gen_image_surface_second_order`
fuzzy_entropy ( Regions, Image : : Apar, Cpar : Entropy )

Determine the fuzzy entropy of regions.

fuzzy_entropy calculates the fuzzy entropy of a fuzzy set. To do so, the image is regarded as a fuzzy set. The entropy then is a measure of how well the image approximates a white or black image. It is defined as follows:

\[ H(X) = \frac{1}{M \times N} \sum_l T_e(l) h(l) \]

where \( M \times N \) is the size of the image, and \( h(l) \) is the histogram of the image. Furthermore,

\[ T_e(l) = -\mu(l) \ln \mu(l) - (1 - \mu(l)) \ln(1 - \mu(l)) \]

Here, \( u(x(m,n)) \) is a fuzzy membership function defining the fuzzy set (see fuzzy_perimeter). The same restrictions hold as in fuzzy_perimeter.

Attention

Note that for fuzzy_entropy, the Regions must lie completely within the previously defined domain. Otherwise an exception is raised.

Parameters

- **Regions** (input_object) ......................................................... region(-array) \( \sim \) object
  - Regions for which the fuzzy entropy is to be calculated.
- **Image** (input_object) ......................................................... singlechannelimage \( \sim \) object : byte
  - Input image containing the fuzzy membership values.
- **Apar** (input_control) ......................................................... integer \( \sim \) integer
  - Start of the fuzzy function.
  - Default value: 0
  - Suggested values: \( Apar \in \{0, 5, 10, 20, 50, 100\} \)
  - Typical range of values: \( 0 \leq Apar \leq 255 \) (lin)
  - Minimum increment: 1
  - Recommended increment: 5
- **Cpar** (input_control) ......................................................... integer \( \sim \) integer
  - End of the fuzzy function.
  - Default value: 255
  - Suggested values: \( Cpar \in \{50, 100, 150, 200, 220, 255\} \)
  - Typical range of values: \( 0 \leq Cpar \leq 255 \) (lin)
  - Minimum increment: 1
  - Recommended increment: 5
  - Restriction: \( Apar \leq Cpar \)
- **Entropy** (output_control) ......................................................... real(-array) \( \sim \) real
  - Fuzzy entropy of a region.

Example

* To find a Fuzzy Entropy from an Image
  read_image(Image, 'monkey')
  fuzzy_entropy(Trans, Trans, 0, 255, Entro)

Result

The operator fuzzy_entropy returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

fuzzy_perimeter ( Regions, Image : : Apar, Cpar : Perimeter )

Calculate the fuzzy perimeter of a region.
The operator fuzzy_perimeter is used to determine the differences of fuzzy membership between an image point and its neighbor points. The right and lower neighbor are taken into account. The fuzzy perimeter is then defined as follows:

\[
p(X) = \sum_{m=1}^{M-1} \sum_{n=1}^{N-1} |\mu_X(x_{m,n}) - \mu_X(x_{m,n+1})| + \sum_{m=1}^{M-1} \sum_{n=1}^{N-1} |\mu_X(x_{m,n}) - \mu_X(x_{m+1,n})|
\]

where \( M \times N \) is the size of the image, and \( u(x(m,n)) \) is the fuzzy membership function (i.e., the input image). This implementation uses Zadeh’s Standard-S function, which is defined as follows:

\[
\mu_X(x) = \begin{cases} 
0, & x \leq a \\
\frac{2}{\Delta b} \left( \frac{x-a}{c-a} \right)^2, & a < x \leq b \\
1 - 2 \left( \frac{x-a}{c-a} \right)^2, & b < x \leq c \\
1, & c \leq x
\end{cases}
\]

The parameters \( a, b \) and \( c \) obey the following restrictions: \( b = \frac{a + c}{2} \) is the inflection point of the function, \( \Delta b = b - a = c - b \) is the bandwidth, and for \( x = b \) \( \mu(x) = 0.5 \) holds. In fuzzy_perimeter, the parameters Apar and Cpar are defined as follows: \( b = \frac{Apar + Cpar}{2} \).

Attention
Note that for fuzzy_perimeter, the Regions must lie completely within the previously defined domain. Otherwise an exception is raised.

Parameters

▷ Regions (input_object) ........................................................... region(-array) ~ object

Regions for which the fuzzy perimeter is to be calculated.

▷ Image (input_object) .......................................................... singlechannelimage ~ object : byte

Input image containing the fuzzy membership values.

▷ Apar (input_control) .......................................................... integer ~ integer

Start of the fuzzy function.

Default value: 0
Suggested values: \( Apar \in \{0, 5, 10, 20, 50, 100\} \)
Typical range of values: \( 0 \leq Apar \leq 255 \) (lin)
Minimum increment: 1
Recommended increment: 5
15.6. FEATURES

⊿ Cpar (input_control) ............................................................ integer \sim integer
End of the fuzzy function.

Default value: 255  
Suggested values: Cpar \in \{50, 100, 150, 200, 220, 255\}

Typical range of values: 0 \leq Cpar \leq 255 (lin)
Minimum increment: 1
Recommended increment: 5
Restriction: Apar <= Cpar

⊿ Perimeter (output_control) .......................................................... real(-array) \sim real
Fuzzy perimeter of a region.

Example

* To find a Fuzzy Entropy from an Image
read_image(Image,'monkey')
fuzzy_perimeter(Trans,Trans,0,255,Per)

Result

The operator fuzzy_perimeter returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Foundation

gen_cooc_matrix ( Regions, Image : Matrix : LdGray, Direction : )

Calculate the co-occurrence matrix of a region in an image.
The operator gen_cooc_matrix determines from the input regions how often the gray values i and j are located next to each other in a certain direction (0, 45, 90, 135 degrees), stores this number in the co-occurrence matrix at the locations (i,j) and (j,i) (the matrix is symmetrical), and finally scales the matrix with the number of entries. LdGray indicates the number of gray values to be distinguished (namely 2^{LdGray}).

Example:

Input image with gray values (scaled with LdGray=2)

0 0 3
1 1 2
1 2 3

Co-occurrence matrices (not scaled)

0:

\begin{array}{ccc}
2 & 0 & 0 \\
0 & 2 & 2 \\
1 & 0 & 1
\end{array}

135:

\begin{array}{ccc}
0 & 1 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{array}

90:

\begin{array}{ccc}
0 & 2 & 0 \\
2 & 2 & 1 \\
1 & 0 & 2
\end{array}

45:

\begin{array}{ccc}
0 & 1 & 0 \\
1 & 2 & 0 \\
0 & 0 & 2
\end{array}

HALCON 20.05.0.0
Attention

Note that the operator `gen_cooc_matrix` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

---

### Parameters

- **Regions** (input_object)  
  Region to be checked.

- **Image** (input_object)  
  Image providing the gray values.

- **Matrix** (output_object)  
  Co-occurrence matrix (matrices).

- **LdGray** (input_control)  
  Number of gray values to be distinguished ($2^{LdGray}$).
  Default value: 6
  List of values: $LdGray \in \{1, 2, 3, 4, 5, 6, 7, 8\}$
  Minimum increment: 1
  Recommended increment: 1

- **Direction** (input_control)  
  Direction of neighbor relation.
  Default value: 0
  List of values: $Direction \in \{0, 45, 90, 135\}$

---

**Result**

The operator `gen_cooc_matrix` returns the value 2 (`H_MSG_TRUE`) if an image with defined gray values is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)`, the behavior in case of empty region is set via `set_system(::'empty_region_result',<Result>:)`. If necessary an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**gray_features** (Regions, Image : : Features : Value )

Calculates gray value features for a set of regions.

`gray_features` has a set of regions (`Regions`) as input. For each of these regions the features (`Features`) are calculated and returned in `Value`. Possible values for `Features`:

- **'area’** Gray value volume of region (see area_center_gray)
- **'row’** Row index of the center of gravity (see area_center_gray)
- **'column’** Column index of the center of gravity (see area_center_gray)
- **'ra’** Major axis of equivalent ellipse (see elliptic_axis_gray)
'rb'  Minor axis of equivalent ellipse (see elliptic_axis_gray)
'phi'  Orientation of equivalent ellipse (see elliptic_axis_gray)
'min'  Minimum gray value (see min_max_gray)
'max'  Maximum gray value (see min_max_gray)
'median'  Median gray value (see min_max_gray, with Percent=50)
'mean'  Mean gray value (see intensity)
'deviation'  Deviation of gray values (see intensity)
'plane_deviation'  Deviation from the approximating plane (see plane_deviation)
'anisotropy'  Anisotropy (see entropy_gray)
'entropy'  Entropy (see entropy_gray)
'fuzzy_entropy'  Fuzzy entropy of region (see fuzzy_entropy, with a fuzzy function from Apar=0 to Cpar=255)
'fuzzy_perimeter'  Fuzzy perimeter of region (see fuzzy_perimeter, with a fuzzy function from Apar=0 to Cpar=255)
'moments_row'  Mixed moments along a row (see moments_gray_plane)
'moments_column'  Mixed moments along a column (see moments_gray_plane)
'alpha'  Approximating plane, parameter Alpha (see moments_gray_plane)
'beta'  Approximating plane, parameter Beta (see moments_gray_plane)

Attention

Several features are processed in the order in which they are entered.

Note that the operator gray_features only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

▷ Regions (input_object) .................................................. region-array  ~ object
  Regions to be examined.
▷ Image (input_object) ...... singlechannelimage  ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  Gray value image.
▷ Features (input_control) .............................................. string(-array)  ~ string
  Names of the features.
  Default value: 'mean'
  List of values: Features ∈ {'area', 'row', 'column', 'ra', 'rb', 'phi', 'min', 'max', 'median', 'mean',
  'deviation', 'plane_deviation', 'anisotropy', 'entropy', 'fuzzy_entropy', 'fuzzy_perimeter', 'moments_row',
  'moments_column', 'alpha', 'beta'}
▷ Value (output_control) ................................................. real(-array)  ~ real
  Value of the features.

Complexity

If $F$ is the area of the region and $N$ the number of features the runtime complexity is $O(F \times N)$.

Result

The operator gray_features returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. If necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

**gray_histo** ( Regions, Image : : : AbsoluteHisto, RelativeHisto )

*Calculate the gray value distribution.*

The operator `gray_histo` calculates for the image (Image) within Regions the absolute (AbsoluteHisto) and relative (RelativeHisto) histogram of the gray values.

Both histograms are tuples of 256 values, which — beginning at 0 — contain the frequencies of the individual gray values of the image.

**AbsoluteHisto** indicates the absolute frequencies of the gray values in integers, and **RelativeHisto** indicates the relative, i.e. the absolute frequencies divided by the area of the image as floating point numbers.

'real', 'int2', 'uint2', and 'int4'-images are transformed into 'byte'-images (first the largest and smallest gray value in the image are determined, and then the original gray values are mapped linearly into the area 0..255) and then processed as mentioned above. The histogram can also be returned directly as a graphic via the operators `set_paint(::WindowHandle,'histogram':)` and `disp_image`.

**Attention**

Note that the operator `gray_histo` only considers the given Regions and ignores any previously set domain of the input image Image.

Real, int2, uint2, and int4 images are reduced to 256 gray values.

`gray_histo` can be executed on OpenCL devices for byte, int1, directional and cyclic images if the OpenCL device supports the cl_khr_local_int32_base_atomics and cl_khr_global_int32_base_atomics extensions (which are optional in OpenCL 1.0). Unlike most other HALCON operators, `gray_histo` can be substantially slower on an OpenCL device if the Image is not completely included in the Regions.

OpenCL support is not available in HALCON XL, as 64 bit atomic integer arithmetic would be required.

**Parameters**

- **Regions** (input_object)  
  Region in which the histogram is to be calculated.

- **Image** (input_object)  
  Image the gray value distribution of which is to be calculated.

- **AbsoluteHisto** (output_control)  
  Absolute frequencies of the gray values.

- **RelativeHisto** (output_control)  
  Frequencies, normalized to the area of the region.

**Complexity**

If F is the area of the region the runtime complexity is O(F + 255).

**Result**

The operator `gray_histo` returns the value 2 (H_MSG_TRUE) if the image has defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)`; the behavior in case of empty region is set via `set_system(::'empty_region_result',<Result>:)`; If necessary an exception is raised.

**Parallelization**

• Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Possible Successors

histo_to_thresh, gen_region_histo

Alternatives

min_max_gray, intensity, gray_histo_abs, gray_histo_range

See also

set_paint, disp_image, histo_2dim, scale_image_max, entropy_gray

Module

Foundation

gray_histo_abs ( Regions, Image : : Quantization : AbsoluteHisto )

Calculate the gray value distribution.

The operator gray_histo_abs calculates for the image (Image) within Regions the absolute (AbsoluteHist) histogram of the gray values.

The parameter Quantization defines, how many frequencies of neighbored gray values are added for one frequency value. The resulting histogram AbsoluteHist is a tuple, whose indices are mapped on the gray values of the input image Image and whose elements contain the frequencies of the gray values. The indices \( i \) of the frequency value are calculated from the gray values \( g \) and the quantisation \( q \) as follows:

\[
i = \left\lceil \frac{g + 0.5}{q} \right\rceil \quad \text{for unsigned image types},
\]

\[
i = \left\lceil \frac{g - (\text{MIN} - 0.5)}{q} \right\rceil \quad \text{for signed image types},
\]

whereas MIN denotes the minimal gray value, e.g., -128 for an int1 image type. Therefore, the size of the tuple results from the ratio of the full domain of gray values and the quantisation, e.g. for images of int2 in \( \left[ \frac{65536}{33} \right] \approx 21846 \). The origin gray value of the signed image types int1 resp. int2 is mapped on the index 128 resp. 32768, negative resp. positive gray values have smaller resp. greater indices.

The histogram can also be returned directly as a graphic via the operators set_paint(:: WindowHandle,’histogram’) and disp_image.

Attention

Note that the operator gray_histo_abs only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

\( \triangleright \) Regions (input_object) : region(-array) \~ object Region in which the histogram is to be calculated.

\( \triangleright \) Image (input_object) : singlechannelimage \~ object : byte / cyclic / direction / int1 / int2 / uint2 Image the gray value distribution of which is to be calculated.

\( \triangleright \) Quantization (input_control) : number \~ real / integer Quantization of the gray values.

Default value: 1.0

Suggested values: Quantization ∈ \{1.0, 2.0, 3.0, 5.0, 10.0\}

Restriction: Quantization \( \geq 1.0 \)

\( \triangleright \) AbsoluteHisto (output_control) : histogram-array \~ integer Absolute frequencies of the gray values.
**Result**
The operator `gray_histo_abs` returns the value 2 (H_MSG_TRUE) if the image has defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)`, the behavior in case of empty region is set via `set_system(::'empty_region_result',<Result>:)`. If necessary an exception is raised.

**Parallelization**

**Module**

<table>
<thead>
<tr>
<th>gray_histo_range</th>
<th>( Regions, Image : : Min, Max, NumBins : Histo, BinSize )</th>
</tr>
</thead>
</table>

Calculate the gray value distribution of a single channel image within a certain gray value range.

`gray_histo_range` calculates the gray value distribution `Histo` of the single channel `Image` within `Regions` and the gray value range `[Min,Max]`. The values for `Min` and `Max` are rounded down to the next integer if the `Image` is not of type `real`. The gray value range is divided into `NumBins` bins of the same size, which is returned in `BinSize`. If a gray value lies between two bins the gray value is assigned to the smaller bin.

If the `Image` is of type `real` `BinSize = \frac{\text{Max} - \text{Min}}{\text{NumBins}}`. If the `Image` has discrete gray values the size of a bin is computed with `BinSize = \frac{\text{Max} - \text{Min} + 1}{\text{NumBins}}`. Since the accuracy of the histogram `Histo` can be adjusted with `NumBins`, the calculation of the gray value histogram with `gray_histo_range` is most useful for images of type `real` and images of type `integer`, which have a high bit depth.

**Attention**
Note that the operator `gray_histo_range` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

If the `Image` has discrete gray values the value of `BinSize` may cause the following effects: For `BinSize > 1` multiple neighboring gray values are assigned to the same bin. If `BinSize` is an integer the gray values are distributed uneven among the bins, e.g., for `BinSize = 1.5` the first and second gray value are assigned to the first bin, the third gray value is assigned to the second bin, and the fourth and fifth gray value are assigned to the third bin. This becomes noticeable in several peeks in the histogram `Histo`. If `BinSize < 1` some classes are not assigned by any gray value, e.g., for `BinSize = 0.5` the first gray value is assigned to the first bin and the second gray value is assigned to the third bin. The histogram `Histo` shows some gaps, which resembles the structure of a comb.

If the `Image` is of type `real` and `Min = Max`, all pixels of the corresponding gray value are assigned only to the first bin.

**Parameters**

- **Regions** (input_object) .......................................................... region(-array) ➔ object
  Region in which the histogram is to be calculated.
- **Image** (input_object) ................................ singlechannelimage ➔ object : byte / cyclic / direction / int1 / uint2 / int2 / int4 / int8 / real
  Input image.
15.6. FEATURES

Min (input_control) ................................................................. real → real / integer
Minimum gray value.
Default value: 0
Suggested values: Min ∈ \{0\}

Max (input_control) ................................................................. real → real / integer
Maximum gray value.
Default value: 255
Suggested values: Max ∈ \{255\}
Restriction: Max ≥ Min

NumBins (input_control) .......................................................... integer → integer
Number of bins.
Default value: 256
Suggested values: NumBins ∈ \{16, 32, 64, 128, 256\}
Restriction: NumBins ≥ 1

Histo (output_control) ........................................................... histogram(-array) → integer
Histogram to be calculated.

BinSize (output_control) .......................................................... real → real
Bin size.

If the parameters are valid, the operator gray_histo_range returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Module

gray_projections ( Region, Image : : Mode : HorProjection, VertProjection )

Calculate horizontal and vertical gray-value projections.

gray_projections calculates the horizontal and vertical gray-value projections, i.e., the mean values in the horizontal and vertical direction of the gray values of the input image Image within the input region Region.

If Mode = 'simple' is selected the projection is performed in the direction of the coordinate axes of the image, i.e.:

\[
\text{HorProjection}(r) = \frac{1}{n(r+r')} \sum_{(r+r',c+c') \in \text{Region}} \text{Image}(r+r',c+c')
\]

\[
\text{VertProjection}(c) = \frac{1}{n(c+c')} \sum_{(r+r',c+c') \in \text{Region}} \text{Image}(r+r',c+c')
\]
Here, \((r', c')\) denotes the upper left corner of the smallest enclosing axis-parallel rectangle of the input region (see \texttt{smallest_rectangle1}), and \(n(x)\) denotes the number of region points in the corresponding row \(r + r'\) or column \(c + c'\). Hence, the horizontal projection returns a one-dimensional function that reflects the vertical gray value changes. Likewise, the vertical projection returns a function that reflects the horizontal gray value changes.

If \(\text{Mode} = \text{'rectangle'}\) is selected the projection is performed in the direction of the major axes of the smallest enclosing rectangle of arbitrary orientation of the input region (see \texttt{smallest_rectangle2}). Here, the horizontal projection direction corresponds to the larger axis, while the vertical direction corresponds to the smaller axis. In this mode, all gray values within the smallest enclosing rectangle of arbitrary orientation of the input region are used to compute the projections.

Attention

The operator \texttt{gray_projections} only considers the given \texttt{Region} and ignores any previously set domain of the input image \texttt{Image}.

If \(n(x) = 0\), i.e., if there are no region points in the corresponding row \(r + r'\) or column \(c + c'\), the respective value of \texttt{HorProjection} or \texttt{VertProjection} is set to \(-1\).

\texttt{gray_projections} can be executed on an OpenCL device for the 'simple' mode if the OpenCL device supports the cl\_khr\_global\_int32\_base\_atomics OpenCL extension. For processing images of type real, the OpenCL device must support the cl\_khr\_fp64 and cl\_khr\_int64\_base\_atomics extensions.

**Parameters**

- \(\text{Region} \ (\text{input}_\text{object})\) \hspace{1cm} \text{region} \sim \text{object}
  Region to be processed.
- \(\text{Image} \ (\text{input}_\text{object})\) \hspace{1cm} \text{singlechannelimage} \sim \text{object} : \text{byte / int2 / uint2 / real}
  Grayvalues for projections.
- \(\text{Mode} \ (\text{input}_\text{control})\) \hspace{1cm} \text{string} \sim \text{string}
  Method to compute the projections.
  \textbf{Default value}: 'simple'
  \textbf{List of values}: Mode \in \{ 'simple', 'rectangle' \}
- \(\text{HorProjection} \ (\text{output}_\text{control})\) \hspace{1cm} \text{real-array} \sim \text{real}
  Horizontal projection.
- \(\text{VertProjection} \ (\text{output}_\text{control})\) \hspace{1cm} \text{real-array} \sim \text{real}
  Vertical projection.

**Parallelization**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

\begin{verbatim}
halcon_1dMetrology
\end{verbatim}

\begin{verbatim}
histo_2dim ( Regions, ImageCol, ImageRow : Histo2Dim : )
\end{verbatim}

Calculate the histogram of two-channel gray value images.

The operator \texttt{histo_2dim} calculates the 2-dimensional histogram of two images within \texttt{Regions}. The gray values of channel 1 (\texttt{ImageCol}) are interpreted as row index, those of channel 2 (\texttt{ImageRow}) as column index. The gray value at one point \(P(g_1, g_2)\) in the output image \texttt{Histo2Dim} indicates the frequency of the gray value combination \((g_1, g_2)\) with \(g_1\) indicating the line index and \(g_2\) the column index.

Attention

Note that the operator \texttt{histo_2dim} only considers the given \texttt{Regions} and ignores any previously set domain of the input images.
15.6. FEATURES

Parameter

- **Regions** (input_object) .......................... region(-array) \(\leadsto\) object  
  Region in which the histogram is to be calculated.
- **ImageCol** (input_object) ......................... (multichannel-)image \(\leadsto\) object : byte / direction / cyclic / int1  
  Channel 1.
- **ImageRow** (input_object) ......................... (multichannel-)image \(\leadsto\) object : byte / direction / cyclic / int1  
  Channel 2.
- **Histo2Dim** (output_object) ........................ image \(\leadsto\) object : int4  
  Histogram to be calculated.

Example

```
read_image(Image,'monkey')
get_domain(Image, Domain)
gauss_filter(Image, ImageGauss, 7)
histo_2dim(Domain,ImageGauss, Image,Histo2Dim)
develop_display(Histo2Dim)
```

Complexity

If \( F \) is the plane of the region, the runtime complexity is \( O(F + 256^2) \).

Result

The operator histo_2dim returns the value 2 (H_MSG_TRUE) if both images have defined gray values. The behavior in case of empty input (no input images available) is set via the operator set_system(\#: 'no_object_result',<Result>:), the behavior in case of empty region is set via set_system(\#: 'empty_region_result',<Result>:). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Predecessors

decompose3, decompose2, draw_region

Successors

threshold, class_2dim_sup, pouring, local_max, gray_skeleton

Alternatives

gray_histo, gray_histo_abs

See also

get_grayval

Module

intensity (Regions, Image : : : Mean, Deviation )

Calculate the mean and deviation of gray values.

The operator intensity calculates the mean and the deviation of the gray values in the input image within Regions. If \( R \) is a region, \( p \) a pixel from \( R \) with the gray value \( g(p) \) and \( F \) the plane (\( F = |R| \)), the features are defined by:

\[
\text{Mean} := \frac{\sum_{p \in R} g(p)}{F}
\]

\[
\text{Deviation} := \sqrt{\frac{\sum_{p \in R} (g(p) - \text{Mean})^2}{F}}
\]
Attention

Note that the operator intensity only considers the given Regions and ignores any previously set domain of the input image Image. The calculation of Deviation does not follow the usual definition if the region of the image contains only one pixel. In this case 0.0 is returned.

Parameters

- **Regions (input_object)**: region(-array) object
  Regions in which the features are calculated.
- **Image (input_object)**: singlechannelimage object
  Gray value image.
- **Mean (output_control)**: real(-array) real
  Mean gray value of a region.
- **Deviation (output_control)**: real(-array) real
  Deviation of gray values within a region.

Complexity

If \( F \) is the area of the region, the runtime complexity is \( O(F) \).

Result

The operator intensity returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system(::’no_object_result’,<Result>:), the behavior in case of empty region is set via set_system(::’empty_region_result’,<Result>:). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

threshold

Alternatives

select_gray, min_max_gray

See also

mean_image, gray_histo, gray_histo_abs

Module

Foundation

min_max_gray ( Regions, Image : : Percent : Min, Max, Range )

Determine the minimum and maximum gray values within regions.

The operator min_max_gray creates the histogram of the absolute frequencies of the gray values within Regions in the input image Image (see gray_histo) and calculates the number of pixels Percent corresponding to the area of the input image. Then it goes inwards on both sides of the histogram by this number of pixels and determines the smallest and the largest gray value:

e.g.:

Area = 60, percent = 5, i.e. 3 pixels
  histogram = [2,8,0,7,13,0,0,…,0,10,10,5,3,1,1]
  \Rightarrow Maximum = 255, Minimum = 0, Range = 255

min_max_gray returns: Maximum = 253, Minimum = 1, Range = 252

For images of type int4, int8, and real, the above calculation is not performed via histograms, but using a rank selection algorithm. If Percent is set to 50, Min = Max = Median. If Percent is 0 no histogram is calculated in order to enhance the runtime.
Attention

Note that the operator `min_max_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

### Parameters

- **Regions** (input_object)  region(-array) \(\leadsto\) object
  Regions, the features of which are to be calculated.
- **Image** (input_object)  singlechannelimage \(\leadsto\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Gray value image.
- **Percent** (input_control)  number \(\leadsto\) real / integer
  Percentage below (above) the absolute maximum (minimum).
  **Default value:** 0
  **Suggested values:** `Percent \in \{0, 1, 2, 5, 7, 10, 15, 20, 30, 40, 50\}`
  **Restriction:** \(0 \leq \text{Percent} \leq 50\)
- **Min** (output_control)  real(-array) \(\leadsto\) real
  “Minimum” gray value.
- **Max** (output_control)  real(-array) \(\leadsto\) real
  “Maximum” gray value.
  **Assertion:** `Max \geq Min`
- **Range** (output_control)  real(-array) \(\leadsto\) real
  Difference between `Max` and `Min`.
  **Assertion:** `Range \geq 0`

### Example

* Threshold segmentation with training region:
  ```
  read_image(Image,'fabrik')
  draw_region(Region,WindowHandle)
  min_max_gray(Region,Image,5,Min,Max,Range)
  threshold(Image,SegmentedRegion,Min,Max)
  dev_display(SegmentedRegion)
  ```

### Result

The operator `min_max_gray` returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(:'no_object_result',<Result>:)`. The behaviour in case of an empty region is set via the operator `set_system(:'empty_region_result',<Result>:)`. If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

draw_region, gen_circle, gen_ellipse, gen_rectangle1, threshold, regiongrowing

### Possible Successors

threshold

### Alternatives

select_gray, intensity

### See also

gray_histo, scale_image, scale_image_max, learn_ndim_norm

### Module

Foundation
moments_gray_plane ( Regions, Image : : : MRow, MCol, Alpha, Beta, Mean )

Calculate gray value moments and approximation by a plane.

The operator `moments_gray_plane` calculates the gray value moments and the parameters of the approximation of the gray values by a plane. The calculation is carried out according to the following formula:

\[
M_{\text{Row}} = \frac{1}{F^2} \sum_{(r,c) \in \text{Regions}} (r - \bar{r})(\text{Image}(r,c) - \text{Mean})
\]

\[
M_{\text{Col}} = \frac{1}{F^2} \sum_{(r,c) \in \text{Regions}} (c - \bar{c})(\text{Image}(r,c) - \text{Mean})
\]

\[
\alpha = \frac{M_{\text{Row}} F m_{02} - m_{11} M_{\text{Col}}}{m_{20} m_{02} - m_{11}^2} \quad \beta = \frac{m_{20} M_{\text{Col}} F - M_{\text{Row}} F m_{11}}{m_{20} m_{02} - m_{11}^2}
\]

where \( F \) is the plane, \( \bar{r}, \bar{c} \) the center, and \( m_{11}, m_{20}, \) and \( m_{02} \) the scaled moments of \( \text{Regions} \).

The parameters \( \alpha, \beta \) and \( \text{Mean} \) describe a plane above the region:

\[
\text{Image}'(r,c) = \alpha(r - \bar{r}) + \beta(c - \bar{c}) + \text{Mean}
\]

Thus \( \alpha \) indicates the gradient in the direction of the line axis ("down"), \( \beta \) the gradient in the direction of the column axis (to the "right").

Attention

Note that the operator `moments_gray_plane` only considers the given \( \text{Regions} \) and ignores any previously set domain of the input image \( \text{Image} \).

Parameters

- `Regions` (input_object) \( \cdots \) \( \text{region(-array)} \) \( \sim \) object
  Regions to be checked.
- `Image` (input_object) \( \cdots \) \( \text{singlechannelimage} \) \( \sim \) object : byte / direction / cyclic / uint2 / real
  Corresponding gray values.
- `MRow` (output_control) \( \cdots \) \( \text{real(-array)} \) \( \sim \) real
  Mixed moments along a line.
- `MCol` (output_control) \( \cdots \) \( \text{real(-array)} \) \( \sim \) real
  Mixed moments along a column.
- `Alpha` (output_control) \( \cdots \) \( \text{real(-array)} \) \( \sim \) real
  Parameter \( \alpha \) of the approximating plane.
- `Beta` (output_control) \( \cdots \) \( \text{real(-array)} \) \( \sim \) real
  Parameter \( \beta \) of the approximating plane.
- `Mean` (output_control) \( \cdots \) \( \text{real(-array)} \) \( \sim \) real
  Mean gray value.

Result

The operator `moments_gray_plane` returns the value 2 (H_MSG_TRUE) if an image with the defined gray values ("byte") is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)`; the behavior in case of empty region is set via `set_system(::'empty_region_result',<Result>:)`; if necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`draw_region, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, threshold, regiongrowing`

15.6. FEATURES

Module

plane_deviation ( Regions, Image : : : Deviation )

Calculate the deviation of the gray values from the approximating image plane.

The operator plane_deviation calculates the deviation of the gray values in Image from the approximation of the gray values through a plane. Contrary to the standard deviation in case of intensity slanted gray value planes also receive the value zero. The gray value plane is calculated according to gen_image_gray_ramp. If \( F \) is the area of the region, \( \alpha \), \( \beta \), and \( \mu \) the parameters of the image plane, and \( (r',c') \) the center of the region, Deviation is defined by:

\[
\text{Deviation} = \sqrt{\frac{\text{sum}_{(r,c) \in \text{Regions}} ((\alpha(r-r') + \beta(c-c') + \mu) - \text{Image}(r,c))^2}{F}}.
\]

Attention

Note that the operator plane_deviation only considers the given Regions and ignores any previously set domain of the input image Image. It should be noted that the calculation of Deviation does not follow the usual definition. It is defined to return the value 0.0 for an image with only one pixel.

Parameters

\( \triangleright \) Regions (input_object) .............................................................. region(-array) \( \leadsto \) object
Regions, of which the plane deviation is to be calculated.

\( \triangleright \) Image (input_object) ......................................................... singlechannelimage \( \leadsto \) object : byte / cyclic
Gray value image.

\( \triangleright \) Deviation (output_control) ..................................................... real(-array) \( \leadsto \) real
Deviation of the gray values within a region.

Complexity

If \( F \) is the area of the region the runtime complexity amounts to \( O(F) \).

Result

The operator plane_deviation returns the value 2 (H_MSG_TRUE) if Image is of the type ‘byte’.
The behavior in case of empty input (no input images available) is set via the operator set_system(:: ‘no_object_result’,<Result>); the behavior in case of empty region is set via set_system(:: ‘empty_region_result’,<Result>);. If necessary an exception is raised.

Parallelization

\( \bullet \) Multithreading type: reentrant (runs in parallel with non-exclusive operators).
\( \bullet \) Multithreading scope: global (may be called from any thread).
\( \bullet \) Automatically parallelized on tuple level.

Alternatives

Module

Foundation
The operator `select_gray` has a number of regions (Regions) as input. For each of these regions the (Features) are calculated. The region is transferred (duplicated) into the output SelectedRegions, if each (Operation = 'and') or at least one (Operation = 'or') of the calculated features is within the limits. The limits are defined by the parameters Min and Max. Thereby, Min and Max can also be set to 'min' or 'max', respectively, corresponding to setting the smallest or largest value possible for this feature. The parameter Image contains an image which returns the gray values for calculating the features. Condition:

\[ \text{Min}, \leq \text{Features}, (\text{Regions, Image}) \leq \text{Max}, \]

- 'area' Gray value volume of region (see `area_center_gray`)
- 'row' Row index of the center of gravity (see `area_center_gray`)
- 'column' Column index of the center of gravity (see `area_center_gray`)
- 'ra' Major axis of equivalent ellipse (see `elliptic_axis_gray`)
- 'rb' Minor axis of equivalent ellipse (see `elliptic_axis_gray`)
- 'phi' Orientation of equivalent ellipse (see `elliptic_axis_gray`)
- 'min' Minimum gray value (see `min_max_gray`)
- 'max' Maximum gray value (see `min_max_gray`)
- 'median' Median gray value (see `min_max_gray`, with Percent=50)
- 'mean' Mean gray value (see `intensity`)
- 'deviation' Deviation of gray values (see `intensity`)
- 'plane_deviation' Deviation from the approximating plane (see `plane_deviation`)
- 'anisotropy' Anisotropy (see `entropy_gray`)
- 'entropy' Entropy (see `entropy_gray`)
- 'fuzzy_entropy' Fuzzy entropy of region (see `fuzzy_entropy`, with a fuzzy function from Apar=0 to Cpar=255)
- 'fuzzy_perimeter' Fuzzy perimeter of region (see `fuzzy_perimeter`, with a fuzzy function from Apar=0 to Cpar=255)
- 'moments_row' Mixed moments along a row (see `moments_gray_plane`)
- 'moments_column' Mixed moments along a column (see `moments_gray_plane`)
- 'alpha' Approximating plane, parameter Alpha (see `moments_gray_plane`)
- 'beta' Approximating plane, parameter Beta (see `moments_gray_plane`)

**Attention**

Note that the operator `select_gray` only considers the given Regions and ignores any previously set domain of the input image Image. If only one feature is used the value of Operation is meaningless. Several features are processed in the order in which they are entered. The maximum number of features is limited to 100.

**Parameters**

- **Regions** (input_object) region-array object
  Regions to be examined.
- **Image** (input_object) singlechannelimage object: byte / direction / cyclic / int1 / int2 / uint2 / uint4 / real
  Gray value image.
- **SelectedRegions** (output_object) region-array object
  Regions having features within the limits.
15.6. FEATURES

Features (input_control) .................................................. string(-array) \sim string

Names of the features.
Default value: 'mean'

Operation (input_control) .................................................. string \sim string

Logical connection of features.
Default value: ‘and’
List of values: Operation ∈ {‘and’, ‘or’}

Min (input_control) .................................................. number(-array) \sim real / integer / string

Lower limit(s) of features or ‘min’.
Default value: 128.0
Suggested values: Min ∈ {0.5, 1.0, 10.0, 20.0, 50.0, 128.0, 255.0, 1000.0, ‘min’}

Max (input_control) .................................................. number(-array) \sim real / integer / string

Upper limit(s) of features or ‘max’.
Default value: 255.0
Suggested values: Max ∈ {0.5, 1.0, 10.0, 20.0, 50.0, 128.0, 255.0, 1000.0, ‘max’}

If $F$ is the area of the region and $N$ the number of features the runtime complexity is $O(F \ast N)$.

Result

The operator select_gray returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(::‘no_object_result’,<Result>:), the behavior in case of empty region is set via set_system(::‘empty_region_result’,<Result>:). If necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors

connection, mean_image, entropy_image, sobel_amp, median_separate

Possible Successors

select_shape, shape_trans, reduce_domain, count_obj

deviation_image, entropy_gray, intensity, mean_image, min_max_gray, select_obj

Module

Foundation

shape_histo_all ( Region, Image : : Feature : AbsoluteHisto,
RelativeHisto )

Determine a histogram of features along all threshold values.

The operator shape_histo_all carries out 255 threshold operations within Region with the gray values of Image. The entry $i$ in the histogram corresponds to the number of connected components/holes of this image segmented with the threshold $i$ (Feature = ‘connected_components’, 'holes') or the mean value of the feature values of the regions segmented in this way (Feature = ‘convexity’, ‘compactness’, ‘anisometry’), respectively.

The histogram can also be displayed directly as a graphic via the operators set_paint(:: WindowHandle,’component_histogram’) and disp_image.

Attention

The operator shape_histo_all expects a region and exactly one gray value image as input. Because of the power of this operator the runtime of shape_histo_all is relatively large!
Note that the operator `shape_histo_all` only considers the given `Region` and ignores any previously set domain of the input image `Image`.

--- Parameters ---

- **Region** (input_object) region \( \rightsquigarrow \) object
  Region in which the features are to be examined.

- **Image** (input_object) \( \rightsquigarrow \) object : byte
  Gray value image.

- **Feature** (input_control) \( \rightsquigarrow \) string
  Feature to be examined.
  Default value: `'connected_components'`
  List of values: `Feature \( \in \{ 'connected_components', 'convexity', 'compactness', 'anisometry', 'holes' \}`

- **AbsoluteHisto** (output_control) \( \rightsquigarrow \) histogram-array
  Absolute distribution of the feature.

- **RelativeHisto** (output_control) \( \rightsquigarrow \) histogram-array
  Relative distribution of the feature.

--- Example ---

* Simulation of shape_histo_all with feature 'connected_components':*
* `my_shape_histo_all(Region, Image, AbsHisto, RelHisto):`
  `reduce_domain(Region, Image, RegionGray)`
  `for i := 0 to 255 by 1`
  `  threshold(RegionGray, Seg, i, 255)`
  `  connect_and_holes(Seg, NumConnected, _)`
  `  AbsHisto[i] := NumConnected`
  `endfor`
  `Sum := 0`
  `for i := 0 to 255 by 1`
  `  Sum := Sum+AbsHisto[i]`
  `endfor`
  `for i := 0 to 255 by 1`
  `  RelHisto[i] := AbsHisto[i]/Sum`
  `endfor`

--- Complexity ---

If \( F \) is the area of the input region and \( N \) the mean number of connected components the runtime complexity is \( O(255(F + \sqrt{F} \sqrt{N})) \).

--- Result ---

The operator `shape_histo_all` returns the value 2 (H_MSG_TRUE) if an image with the defined gray values is entered. The behavior in case of empty input (no input images) is set via the operator `set_system(:: 'no_object_result',<Result>:)`, the behavior in case of empty region is set via `set_system(:: 'empty_region_result',<Result>:)`. If necessary an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Possible Successors ---

`histo_to_thresh, threshold, gen_region_histo`

--- Alternatives ---

`shape_histo_point`

--- See also ---

`connection, convexity, compactness, connect_and_holes, entropy_gray, gray_histo, set_paint, count_obj`
Module

shape_histo_point ( Region, Image : Feature, Row, Column : AbsoluteHisto, RelativeHisto )

Determine a histogram of features along all threshold values.

Like shape_histo_all the operator shape_histo_point carries out 255 threshold value operations within Region with the gray values of Image. Contrary to shape_histo_all only the segmented region containing the pixel (Row, Column) is taken into account here. The entry \( i \) in the histogram then corresponds to the number of holes of this region segmented with the threshold \( i \) (Feature = 'holes') or the feature value of the region (Feature ∈ {'convexity', 'compactness', 'anisometry'}), respectively.

The histogram can also be displayed directly as a graphic via the operators set_paint(::WindowHandle,'component_histogram:') and disp_image.

Attention

Note that the operator shape_histo_point only considers the given Region and ignores any previously set domain of the input image Image.

Parameters

- Region (input_object) . . . region → object
  Region in which the features are to be examined.

- Image (input_object) . . . singlechannelimage → object : byte
  Gray value image.

- Feature (input_control) . . . string → string
  Feature to be examined.
  Default value: 'convexity'
  List of values: Feature ∈ {'convexity', 'compactness', 'anisometry', 'holes'}

- Row (input_control) . . . point.y → integer
  Row of the pixel which the region must contain.
  Default value: 256
  Suggested values: Row ∈ {10, 50, 100, 200, 300, 400}

- Column (input_control) . . . point.x → integer
  Column of the pixel which the region must contain.
  Default value: 256
  Suggested values: Column ∈ {10, 50, 100, 200, 300, 400}

- AbsoluteHisto (output_control) . . . histogram-array → real / integer
  Absolute distribution of the feature.

- RelativeHisto (output_control) . . . histogram-array → real
  Relative distribution of the feature.

Result

The operator shape_histo_point returns the value 2 (H_MSG_TRUE) if an image with defined gray values is entered. The behavior in case of empty input (no input images available) is set via the operator set_system (:'no_object_result',<Result>), the behavior in case of empty region is set via set_system(:'empty_region_result',<Result>). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_mbutton, area_center

Possible Successors

histo_to_thresh, threshold, gen_region_histo
15.7 Format

**change_format** ( Image : ImagePart : Width, Height : )

*Change image size.*

The operator `change_format` increases or decreases the size of the input images to the indicated height or width, respectively. If the image is reduced, parts are cut off at the “right” or “lower” edge of the image, respectively. If the image is enlarged, the additional areas are set to 0. The definition domain of the new image is equal to the domain of the input image, clipped to the size of the new image. No zooming is carried out.

**Parameters**

- **Image** (input_object) ...... (multichannel-)image(-array)  `~` object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Input image.

- **ImagePart** (output_object) ...... (multichannel-)image(-array)  `~` object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Image with new format.

- **Width** (input_control) ................................................................. `~` extent.x  `~` integer
  
  Width of new image.

  Default value: 512

  **Suggested values:** Width ∈ \{32, 64, 128, 256, 512, 768, 1024\}

- **Height** (input_control) ................................................................. `~` extent.y  `~` integer
  
  Height of new image.

  Default value: 512

  **Suggested values:** Height ∈ \{32, 64, 128, 256, 512, 525, 1024\}

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Successors**

- `disp_image`

**Alternatives**

- `crop_part`

**See also**

- `zoom_image_size`, `zoom_image_factor`

**Module**

Foundation

---

**crop_domain** ( Image : ImagePart : : )

*Cut out of defined gray values.*
The operator **crop_domain** cuts a rectangular area from the input images. This rectangle is the smallest surrounding rectangle of the domain of the input image. The new image matrix has the size of the rectangle.

### Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) \( \leadsto \) object : byte / direction / cyclic / int1 / int2 / int8 / real
  
  Input image.

- **ImagePart** (output_object) ...... (multichannel-)image(-array) \( \leadsto \) object : byte / direction / cyclic / int1 / int2 / int8 / real
  
  Image area.

### Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Successors

- disp_image

### Alternatives

- **crop_part**, **crop_rectangle1**, **change_format**, **reduce_domain**

### See also

- zoom_image_size, zoom_image_factor

### Module

**crop_domain_rel** ( Image : ImagePart : Top, Left, Bottom, Right : )

Cut out an image area relative to the domain.

**crop_domain_rel** cuts a rectangular area from the input images. The area is determined by the surrounding rectangle of the domain of the input image. The rectangle can be influenced by the control parameters to modify at the top (**Top**), at the left (**Left**), at the bottom (**Bottom**), and at the right (**Right**). Positive values result in a smaller, negative values in a larger size. If all parameters are set to zero, the region remains unchanged.

### Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) \( \leadsto \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  
  Input image.

- **ImagePart** (output_object) ...... (multichannel-)image(-array) \( \leadsto \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  
  Image area.

- **Top** (input_control) ......................................................... integer \( \leadsto \) integer
  
  Number of rows clipped at the top.
  
  **Default value**: -1
  
  **Suggested values**: Top \( \in \) \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}

- **Left** (input_control) .......................................................... integer \( \leadsto \) integer
  
  Number of columns clipped at the left.
  
  **Default value**: -1
  
  **Suggested values**: Left \( \in \) \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}

- **Bottom** (input_control) ..................................................... integer \( \leadsto \) integer
  
  Number of rows clipped at the bottom.
  
  **Default value**: -1
  
  **Suggested values**: Bottom \( \in \) \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}
\( \textbf{Right} \) (input_control) \hspace{1cm} \textbf{integer} \sim \textbf{integer}

Number of columns clipped at the right.

**Default value:** -1

**Suggested values:** \( \text{Right} \in \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\} \)

---

\( \text{Result} \)

\( \text{crop\_domain\_rel} \) returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system('no\_object\_result',<Result>)` and the behavior in case of an empty input region via `set_system('empty\_region\_result',<Result>)`. If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

---

**Possible Predecessors**

reduce\_domain, threshold, connection, region\_growing, pouring

**Alternatives**

\( \text{crop\_domain}, \text{crop\_rectangle} \)

---

**See also**

\( \text{smallest\_rectangle}, \text{intersection}, \text{gen\_rectangle}, \text{clip\_region} \)

---

**Module**

Foundation

---

\( \textbf{crop\_part} \) ( Image : ImagePart : Row, Column, Width, Height : )

Cut out one or more rectangular image areas.

The operator \( \textbf{crop\_part} \) cuts one or more rectangular area from each of the input images. The areas are indicated by rectangles, which are defined by the coordinates of their upper left corner and by their size. The upper left corners of the rectangles must be within the image. At the right side and at the bottom, the rectangles may exceed the image, but the domain of the output images is set so that only the part that can be derived from the input image is contained. If the rectangular areas fall completely within the image, then each of the resulting images has the size of its corresponding rectangle.

---

**Parameters**

- **Image** (input_object) \hspace{1cm} (multichannel-)image(-array) \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

  Input image.

- **ImagePart** (output_object) \hspace{1cm} (multichannel-)image(-array) \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

  Image area.

- **Row** (input_control) \hspace{1cm} \text{rectangle.origin.y}(-array) \sim \text{integer}

  Line index of upper left corner of image area.

  **Default value:** 100

  **Suggested values:** \( \text{Row} \in \{10, 20, 50, 100, 200, 300, 500\} \)

  **Typical range of values:** \( 0 \leq \text{Row} \leq 1024 \)

- **Column** (input_control) \hspace{1cm} \text{rectangle.origin.x}(-array) \sim \text{integer}

  Column index of upper left corner of image area.

  **Default value:** 100

  **Suggested values:** \( \text{Column} \in \{10, 20, 50, 100, 200, 300, 500\} \)

  **Typical range of values:** \( 0 \leq \text{Column} \leq 1024 \)
### Width (input_control) ........................................ rectangle.extent.x(-array) \sim integer
- **Default value:** 128
- **Suggested values:** Width \in \{32, 64, 128, 256, 512, 768\}
- **Typical range of values:** 0 \leq Width \leq 1024

### Height (input_control) ........................................ rectangle.extent.y(-array) \sim integer
- **Default value:** 128
- **Suggested values:** Height \in \{32, 64, 128, 256, 512, 525\}
- **Typical range of values:** 0 \leq Height \leq 1024

---

**Parallelization**
- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Successors**

---

### **crop_rectangle1** ( Image : ImagePart : Row1, Column1, Row2, Column2 : )

**Cut out one or more rectangular image areas.**

The operator **crop_rectangle1** cuts one or more rectangular areas from each of the input images. The areas are indicated by rectangles, which are defined by the coordinates of their upper left and their lower right corners. The upper left corners must be within the image. At the right side and at the bottom, the rectangles may exceed the image, but the domain of the output images is set so that only the part that can be derived from the input image is contained. If the rectangular areas fall within the image, then each of the resulting images has the size of its corresponding rectangle.

---

### Parameters

- **Image** (input_object) ........ (multichannel-)image(-array) \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
- **Input image.**

- **ImagePart** (output_object) ........ (multichannel-)image(-array) \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
- **Image area.**

- **Row1** (input_control) ...................... rectangle.origin.y(-array) \sim integer
  - **Default value:** 100
  - **Suggested values:** Row1 \in \{10, 20, 50, 100, 200, 300, 500\}
  - **Typical range of values:** 0 \leq Row1 \leq 1024

- **Column1** (input_control) ...................... rectangle.origin.x(-array) \sim integer
  - **Default value:** 100
  - **Suggested values:** Column1 \in \{10, 20, 50, 100, 200, 300, 500\}
  - **Typical range of values:** 0 \leq Column1 \leq 1024
tile_channels (Image : TiledImage : NumColumns, TileOrder : )

Tile multiple images into a large image.

tile_channels tiles an image consisting of multiple channels into a large single-channel image. The input image Image contains Num images of the same size, which are stored in the individual channels. The output image TiledImage contains a single channel image, where the Num input channels have been tiled into NumColumns columns. In particular, this means that tile_channels cannot tile color images. For this purpose, tile_images can be used. The parameter TileOrder determines the order in which the images are copied into the output in the cases in which this is not already determined by NumColumns (i.e., if NumColumns != 1 and NumColumns != Num). If TileOrder = 'horizontal' the images are copied in the horizontal direction, i.e., the second channel of Image will be to the right of the first channel. If TileOrder = 'vertical' the images are copied in the vertical direction, i.e., the second channel of Image will be below the first channel. The domain of TiledImage is obtained by copying the domain of Image to the corresponding locations in the output image. If Num is not a multiple of NumColumns the output image will have undefined gray values in the lower right corner of the image. The output domain will reflect this.

Parameters

- **Image** (input_object) .... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Input image.

- **TiledImage** (output_object) .... singlechannelimage(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Tiled output image.

- **NumColumns** (input_control) ... integer \(\sim\) integer
  Number of columns to use for the output image.
  **Default value:** 1
  **Suggested values:** NumColumns \(\in\) {1, 2, 3, 4, 5, 6, 7}
  **Restriction:** NumColumns \(\geq\) 1

- **TileOrder** (input_control) ... string
  Order in which the images are copied into the output image.
  **Suggested values:** 'horizontal', 'vertical', 'top', 'bottom', 'left', 'right', 'center'
  **Typical range of values:** 'horizontal', 'vertical'

- **Row2** (input_control) ... integer
  Line index of lower right corner of image area.
  **Default value:** 200
  **Suggested values:** Row2 \(\in\) {10, 20, 50, 100, 200, 300, 500}
  **Typical range of values:** 0 \(\leq\) Row2 \(\leq\) 1024

- **Column2** (input_control) ... integer
  Column index of lower right corner of image area.
  **Default value:** 200
  **Suggested values:** Column2 \(\in\) {10, 20, 50, 100, 200, 300, 500}
  **Typical range of values:** 0 \(\leq\) Column2 \(\leq\) 1024

- **Parallelization** ...
  - Supports OpenCL compute devices.

tile_images (Images : TiledImage : NumColumns, TileOrder : )

Tile multiple image objects into a large image.

tile_images tiles multiple input image objects, which must contain the same number of channels, into a large image. The input image object Images contains Num images, which may be of different size. The output image TiledImage contains as many channels as the input images. In the output image the Num input images have been tiled into NumColumns columns. Each tile has the same size, which is determined by the maximum width and height of all input images. If an input image is smaller than the tile size it is copied to the center of the respective tile. The parameter TileOrder determines the order in which the images are copied into the output in the cases in which this is not already determined by NumColumns (i.e., if NumColumns != 1 and NumColumns != Num). If TileOrder = 'horizontal' the images are copied in the horizontal direction, i.e., the second image of Images will be to the right of the first image. If TileOrder = 'vertical' the images are copied in the vertical direction, i.e., the second image of Images will be below the first image. The domain of TiledImage is obtained by copying the domains of Images to the corresponding locations in the output image. If Num is not a multiple of NumColumns the output image will have undefined gray values in the lower right corner of the image. The output domain will reflect this.
Parameters

- **Images** (input_object) ...... (multichannel-)image-array ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Input images.

- **TiledImage** (output_object) ...... (multichannel-)image ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Tiled output image.

- **NumColumns** (input_control) ....................................................... integer ~ integer
  Number of columns to use for the output image.
  Default value: 1
  Suggested values: NumColumns ∈ {1, 2, 3, 4, 5, 6, 7}
  Restriction: NumColumns ≥ 1

- **TileOrder** (input_control) ......................................................... string ~ string
  Order of the input images in the output image.
  Default value: 'vertical'
  List of values: TileOrder ∈ {'horizontal', 'vertical'}

Example

* Grab 5 (multi-channel) images and stack them vertically.

```c
gen_empty_obj (Images)
for I := 1 to 5 by 1
    grab_image_async (ImageGrabbed, AcqHandle, -1)
    concat_obj (Images, ImageGrabbed, Images)
endfor
tile_images (Images, TiledImage, 1, 'vertical')
```

Result

tile_images returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system(::{'no_object_result'}, <Result>:)`. If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

```c
append_channel
tile_channels, tile_images_offset
```

Alternatives

```c
change_format, crop_part, crop_rectangle1
```

See also

Module

```
tile_images_offset ( Images : TiledImage : OffsetRow, OffsetCol,
                    Row1, Col1, Row2, Col2, Width, Height :
                )
```

Tile multiple image objects into a large image with explicit positioning information.

tile_images_offset tiles multiple input image objects, which must contain the same number of channels, into a large image. The input image object Images contains Num images, which may be of different size. The output image TiledImage contains as many channels as the input images. The size of the output image is determined by the parameters Width and Height. The position of the upper left corner of the input images in
the output images is determined by the parameters `OffsetRow` and `OffsetCol`. Both parameters must contain exactly `Num` values. Optionally, each input image can be cropped to an arbitrary rectangle that is smaller than the input image. To do so, the parameters `Row1`, `Col1`, `Row2`, and `Col2` must be set accordingly. If any of these four parameters is set to `-1`, the corresponding input image is not cropped. In any case, all four parameters must contain `Num` values. If the input images are cropped the position parameters `OffsetRow` and `OffsetCol` refer to the upper left corner of the cropped image. If the input images overlap each other in the output image (while taking into account their respective domains), the image with the higher index in `Images` overwrites the image data of the image with the lower index. The domain of `TiledImage` is obtained by copying the domains of `Images` to the corresponding locations in the output image.

**Attention**

If the input images all have the same size and tile the output image exactly, the operator `tile_images` usually will be slightly faster.

**Parameters**

- **Images** (input_object) …… (multichannel-image-array) ⇒ `object` : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  - Input images.
- **TiledImage** (output_object) …… (multichannel-image) ⇒ `object` : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  - Tiled output image.
- **OffsetRow** (input_control) ……………………………………………………………… point.y(-array) ⇒ `integer`
  - Row coordinate of the upper left corner of the input images in the output image.
  - **Default value:** 0
  - **Suggested values:** `OffsetRow` ∈ {0, 50, 100, 150, 200, 250}
- **OffsetCol** (input_control) ……………………………………………………………… point.x(-array) ⇒ `integer`
  - Column coordinate of the upper left corner of the input images in the output image.
  - **Default value:** 0
  - **Suggested values:** `OffsetCol` ∈ {0, 50, 100, 150, 200, 250}
- **Row1** (input_control) ……………………………………………………………… rectangle.origin.y(-array) ⇒ `integer`
  - Row coordinate of the upper left corner of the copied part of the respective input image.
  - **Default value:** -1
  - **Suggested values:** `Row1` ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- **Col1** (input_control) ……………………………………………………………… rectangle.origin.x(-array) ⇒ `integer`
  - Column coordinate of the upper left corner of the copied part of the respective input image.
  - **Default value:** -1
  - **Suggested values:** `Col1` ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- **Row2** (input_control) ……………………………………………………………… rectangle.corner.y(-array) ⇒ `integer`
  - Row coordinate of the lower right corner of the copied part of the respective input image.
  - **Default value:** -1
  - **Suggested values:** `Row2` ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- **Col2** (input_control) ……………………………………………………………… rectangle.corner.x(-array) ⇒ `integer`
  - Column coordinate of the lower right corner of the copied part of the respective input image.
  - **Default value:** -1
  - **Suggested values:** `Col2` ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- **Width** (input_control) ……………………………………………………………… extent.x ⇒ `integer`
  - Width of the output image.
  - **Default value:** 512
  - **Suggested values:** `Width` ∈ {32, 64, 128, 256, 512, 768, 1024, 2048, 4096}
- **Height** (input_control) ……………………………………………………………… extent.y ⇒ `integer`
  - Height of the output image.
  - **Default value:** 512
  - **Suggested values:** `Height` ∈ {32, 64, 128, 256, 512, 525, 1024, 2048, 4096}

**Example**

* Example 1
  * Grab 2 (multi-channel) NTSC images, crop the bottom 5 lines off
  * of each image, the right 5 columns off of the first image, and
* the left five lines off of the second image, and put the cropped images side-by-side.
gen_empty_obj (Images)
for I := 1 to 2 by 1
   grab_image_async (ImageGrabbed, AcqHandle, -1)
   concat_obj (Images, ImageGrabbed, Images)
endfor
tile_images_offset (Images, TiledImage, [0,635], [0,0], [0,0], \ [0,5], [474,474], [634,639], 635, 950)

* Example 2
* Enlarge image by 15 rows and columns on all sides
EnlargeColsBy := 15
EnlargeRowsBy := 15
get_image_pointer1 (Image, Pointer, Type, WidthImage, HeightImage)
tile_images_offset (Image, EnlargedImage, EnlargeRowsBy, EnlargeColsBy, \ -1, -1, -1, -1, WidthImage + EnlargeColsBy*2, \ HeightImage + EnlargeRowsBy*2)

Result
tile_images_offset returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(:: ‘no_object_result’,<Result>). If necessary, an exception is raised.

Paralleliation

15.8 Manipulation

overpaint_gray ( ImageDestination, ImageSource : : : )

Overpaint the gray values of an image.

overpaint_gray copies the gray values of the image given in ImageSource into the image in ImageDestination. Only the gray values of the domain of ImageSource are copied (see reduce_domain).

If you do not want to modify ImageDestination itself, you can use the operator paint_gray, which returns the result in a newly created image.

Attention

overpaint_gray modifies the content of an already existing image (ImageDestination). Besides, even other image objects may be affected. For example, if you created ImageDestination via copy_obj from another image object (or vice versa), overpaint_gray will also modify the image matrix of this other image object. Therefore, overpaint_gray should only be used to overpaint newly created image objects. Typical operators for this task are, e.g., gen_image_const (creates a new image with a specified size), gen_image_proto
15.8. MANIPULATION

(creates an image with the size of a specified prototype image) or **copy_image** (creates an image as the copy of a specified image).

---

**Parameters**

- **ImageDestination** *(input_object) ...... (multichannel-)image* ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field

  Input image to be painted over.

- **ImageSource** *(input_object) ...... (multichannel-)image* ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field

  Input image containing the desired gray values.

---

**Example**

* Copy a circular part of the image 'monkey' into a new image (New1):

```plaintext
read_image(Image,'monkey')
gen_circle(Circle,200,200,150)
reduce_domain(Image,Circle,Mask)
* New image with black (0) background
gen_image_proto(Image,New1,0.0)
* Copy a part of the image 'monkey' into New1
overpaint_gray(New1,Mask)
```

---

**Result**

overpaint_gray returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ImageDestination**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**Possible Predecessors**

paint_region, overpaint_region

---

**Module**

Foundation

---

**overpaint_region** *( Image, Region : : Grayval, Type : )*

Overpaint regions in an image.

**overpaint_region** paints the regions given in **Region** with a constant gray value into the image given in **Image**. These gray values can either be specified for each channel once, valid for all regions, or for each region separately. To define the latter, group the channel gray values *g* of each region and concatenate them to a tuple according to the regions’ order, e.g., for a three channel image:
If the input image is of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. The parameter Type determines whether the region should be painted filled ('fill') or whether only its boundary should be painted ('margin').

If you do not want to modify Image itself, you can use the operator paint_region, which returns the result in a newly created image.

overpaint_region modifies the content of an already existing image (Image). Besides, even other image objects may be affected: For example, if you created Image via copy_obj from another image object (or vice versa), overpaint_region will also modify the image matrix of this other image object. Therefore, overpaint_region should only be used to overpaint newly created image objects. Typical operators for this task are, e.g., gen_image_const (creates a new image with a specified size), gen_image_proto (creates an image with the size of a specified prototype image) or copy_image (creates an image as the copy of a specified image).

Parameters

- Image (input_object) ...... (multichannel-)image ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image in which the regions are to be painted.
- Region (input_object) .............................................. region(-array) ~ object
  Regions to be painted into the input image.
- Grayval (input_control) .............................................. number(-array) ~ real / integer
  Desired gray values of the regions.
  Default value: 255.0
  Suggested values: Grayval ∈ {0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0}
- Type (input_control) .............................................. string ~ string
  Paint regions filled or as boundaries.
  Default value: 'fill'
  List of values: Type ∈ {'fill', 'margin'}

Example

* Paint a rectangle into a new image (New1)

  gen_rectangle1(Rectangle, 100.0, 100.0, 300.0, 300.0)
  * generate a black image
  gen_image_const(New1, 'byte', 768, 576)
  * paint a white rectangle
  overpaint_region(New1, Rectangle, 255.0, 'fill')

Result

overpaint_region returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system (::'no_object_result', <Result>). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- Image
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
read_image, gen_image_const, gen_image_proto, reduce_domain

Alternatives
set_grayval, paint_region, paint_xld

reduce_domain, set_draw, paint_gray, overpaint_gray, gen_image_const

Module
Foundation

**paint_gray** (ImageSource, ImageDestination : MixedImage : :)

Paint the gray values of an image into another image.

**paint_gray** paints the gray values of the image given in **ImageSource** into the image in **ImageDestination** and returns the resulting image in **MixedImage**. Only the gray values of the domain of **ImageSource** are copied (see **reduce_domain**).

As an alternative to **paint_gray**, you can use the operator **overpaint_gray**, which directly paints the gray values into **ImageDestination**.

**Parameters**

- **ImageSource** (input_object) ...... (multichannel-)image ↦ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  
  Input image containing the desired gray values.

- **ImageDestination** (input_object) ...... (multichannel-)image ↦ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  
  Input image to be painted over.

- **MixedImage** (output_object) ...... image ↦ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  
  Result image.

**Example**

* Copy a circular part of the image 'monkey' into the image 'fabrik':

read_image(Image,'monkey')
gen_circle(Circle,200,200,150)
reduce_domain(Image,Circle,Mask)
read_image(Image2,'fabrik')
read_image(Image,'monkey')
paint_gray(Mask,Image2,MixedImage)

**Result**

**paint_gray** returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

paint_region, overpaint_region

**Module**

Foundation

---

**paint_region** ( Region, Image : ImageResult : Grayval, Type : )

*Paint regions into an image.*

paint_region paints the regions given in Region with a constant gray value into the image given in Image and returns the result in ImageResult. These gray values can either be specified for each channel once, valid for all regions, or for each region separately. To define the latter, group the channel gray values \( g \) of each region and concatenate them to a tuple according to the regions’ order, e.g., for a three channel image:

\[ g(\text{channel1}, \text{region1}), g(\text{channel2}, \text{region1}), g(\text{channel3}, \text{region1}), g(\text{channel1}, \text{region2}), \ldots \]

If the input image is of type ’direction’, gray values that are not in the value range that is valid for ’direction’ images are set to the value 255 to mark them as invalid. The parameter Type determines whether the region should be painted filled (’fill’) or whether only its boundary should be painted (’margin’).

As an alternative to paint_region, you can use the operator overpaint_region, which directly paints the regions into Image.

**Parameters**

- **Region** (input_object) ........................................... region(-array) \( \sim \) object
  Regions to be painted into the input image.
- **Image** (input_object) ...... (multichannel-)image \( \sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image in which the regions are to be painted.
- **ImageResult** (output_object) ...... image \( \sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image containing the result.
- **Grayval** (input_control) ........................................... number(-array) \( \sim \) real / integer
  Desired gray values of the regions.
  **Default value:** 255.0
  **Suggested values:** Grayval \( \in \{0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0\}
- **Type** (input_control) ........................................... string \( \sim \) string
  Paint regions filled or as boundaries.
  **Default value:** ’fill’
  **List of values:** Type \( \in \{’fill’, ’margin’\}

**Example**

* Paint a rectangle into the image ’monkey’

read_image(Image,’monkey’)
generate_rectangle(Rectangle,100.0,100.0,300.0,300.0)
* paint a white rectangle
paint_region(Rectangle,Image,ImageResult,255.0,’fill’)

**Result**

paint_region returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::’no_object_result’,<Result>::). If necessary, an exception is raised.

---

**Parallelization**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
read_image, gen_image_const, gen_image_proto, reduce_domain

Alternatives
set_grayval, overpaint_region, paint_xld

See also
reduce_domain, paint_gray, overpaint_gray, set_draw, gen_image_const

Foundation

**paint_xld** ( XLD, Image : ImageResult : Grayval : )

*Paint XLD objects into an image.*

paint_xld paints the XLD objects XLD of type contour or polygon with the constant gray values Grayval into each channel of the background image given in Image and returns the result in ImageResult. Open contours of XLD objects are closed and their enclosed regions are filled up. The rim of the subpixel XLD objects is painted onto the background image using anti-aliasing.

Filling up XLD-objects that have crossings or segments that are very close (lying in neighboring pixels) does not work correctly and leads to artifacts. The set_system parameter ‘neighborhood’ defines whether diagonal neighbors are filled as well as orthogonal neighbors.

Grayval contains the gray values for painting the XLD objects. These gray values can either be specified for each channel once, valid for all XLD objects, or for each XLD object separately. To define the latter, group the channel gray values \( g \) of each XLD object and concatenate them to a tuple according to the order of the XLD objects, e.g., for a three channel image:

\[
g(\text{channel1}, \text{xld1}), g(\text{channel2}, \text{xld1}), g(\text{channel3}, \text{xld1}), g(\text{channel1}, \text{xld2}), \ldots
\]

If the input image is of type ‘direction’, gray values that are not in the value range that is valid for ‘direction’ images are set to the value 255 to mark them as invalid.

**Parameters**

- **XLD** (input_object) .................. xld(-array) \( \rightarrow \) object
  XLD objects to be painted into the input image.
- **Image** (input_object) ....... (multichannel-)image \( \rightarrow \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
  Image in which the xld objects are to be painted.
- **ImageResult** (output_object) ........ image \( \rightarrow \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
  Image containing the result.
- **Grayval** (input_control) .................. number(-array) \( \rightarrow \) real / integer
  Desired gray value of the xld object.

**Default value:** 255.0

**Suggested values:** Grayval \( \in \{ 0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0 \} \)

**Example**

* Paint colored xld objects into a gray image

* read and copy image to generate a three channel image
  read_image(Image1, 'green-dot')
  copy_image(Image1, Image2)
copy_image(Image1,Image3)
compose3(Image1,Image2,Image3,Image)
* extract subpixel border
threshold_sub_pix(Image1,Border,128)
* select the circle and the arrows
select_obj(Border,circle,14)
select_obj(Border,arrows,16)
concat_obj(circle,arrows,green_dot)
* paint a green circle and white arrows (to paint all
* objects e.g. blue, pass [0,0,255] tuple for GrayVal)
paint_xld(green_dot,Image,ImageResult,[0,255,0,255,255,255])

Result

paint_xld returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::{‘no_object_result’,<Result>:}). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
read_image,gen_image_const,gen_image_proto,gen_contour_polygon_xld,
threshold_sub_pix

Alternatives
set_grayval,paint_gray,paint_region

See also

gen_image_const

Module

set_grayval ( Image : : Row, Column, Grayval : )

Set single gray values in an image.

set_grayval sets the gray values of the input image Image at the positions (Row,Column) to the values specified by Grayval. If Image is a multi-channel image, you can either set a single gray value for a pixel and thus set it for all available channels, or you can set the gray values g for all channels individually by concatenating them within Grayval. For example, for a three-channel image three gray values (according to the order of the channels) are specified for each pixel:

\[ g(\text{channel0}, \text{pixel0}), g(\text{channel1}, \text{pixel0}), g(\text{channel2}, \text{pixel0}), g(\text{channel0}, \text{pixel1}), \ldots \]  

Please note that for complex or vector field images, two gray values per pixel must be specified (per channel). If the image is of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid.

Attention

The operator set_grayval produces quite some overhead. Typically, it is used to set single gray values of an image. It is not suitable for programming image processing operations such as filters. In this case it is more useful to use the operator get_image_pointer1 and to directly use the C or C++ interface for integrating own procedures.

Note also that set_grayval modifies the content of an already existing image (Image). Besides, even other image objects may be affected: For example, if you created Image via copy_obj from another image object,
set_grayval will also modify the image matrix of this other image object. Therefore, set_grayval should only be used to overpaint newly created image objects.

**Parameters**

- **Image** (input_object)  
  Image to be modified.

- **Row** (input_control)  
  Row coordinates of the pixels to be modified.

- **Grayval** (input_control)  
  Gray values to be used.

**Return**

set_grayval returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::’no_object_result’,<Result>:). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **Image**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### 15.9 Type Conversion

**complex_to_real** (ImageComplex : ImageReal, ImageImaginary : :)

Convert a complex image into two real images.

complex_to_real converts a complex image ImageComplex into two real images ImageReal and ImageImaginary, which contain the real and imaginary part of the complex image.
Parameters

- **ImageComplex** (input_object) ... singlechannelimage(-array) \(\sim\) object : complex
  Complex image.

- **ImageReal** (output_object) ... image(-array) \(\Rightarrow\) object : real
  Real part.

- **ImageImaginary** (output_object) ... image(-array) \(\Rightarrow\) object : real
  Imaginary part.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

See also

real_to_complex

Module

Foundation

**convert_image_type** ( Image : ImageConverted : NewType : )

Convert the type of an image.

`convert_image_type` converts images of an arbitrary type into an arbitrary new image type. If the conversion is done from a larger to a smaller gray value range (e.g., from 'int4' to 'byte'), too large or too small values are simply "clipped". If the result images are of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. It is therefore advisable to adapt the range of gray values by calling `scale_image` before calling this operator. For images of type complex, only the real part is converted. The imaginary part is ignored. This facilitates an efficient conversion of images that have been transformed back from the frequency domain. Such images always have an imaginary part of 0.

Attention

The conversion to the 'int8' image format is only available on 64 bit systems! If the source and destination image type are identical, no new image matrix is allocated.

Parameters

- **Image** (input_object) ... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image whose image type is to be changed.

- **ImageConverted** (output_object) ... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Converted image.

- **NewType** (input_control) ... string \(\sim\) string
  Desired image type (i.e., type of the gray values).
  Default value: 'byte'
  List of values: NewType \(\in\) {'int1', 'int2', 'uint2', 'int4', 'int8', 'byte', 'real', 'direction', 'cyclic', 'complex'}

Result

`convert_image_type` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Parallelization

- Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on domain level.

Possible Predecessors

scale_image

Module

Foundation

real_to_complex ( ImageReal, ImageImaginary : ImageComplex : : )

Convert two real images into a complex image.

real_to_complex converts two real images ImageReal and ImageImaginary, which contain the real and imaginary part of a complex image, into a complex image ImageComplex.

Parameters

▷ ImageReal (input_object) singlechannelimage(-array) object : real
  Real part.
▷ ImageImaginary (input_object) singlechannelimage(-array) object : real
  Imaginary part.
▷ ImageComplex (output_object) image(-array) object : complex
  Complex image.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

complex_to_real

Module

Foundation

real_to_vector_field ( Row, Col : VectorField : Type : )

Convert two real-valued images into a vector field image.

real_to_vector_field converts two real-valued images Row and Col into a vector field image VectorField. The input images contain the vector components in the row and column direction, respectively. The semantic type of VectorField is set with Type.

Parameters

▷ Row (input_object) singlechannelimage(-array) object : real
  Vector component in the row direction.
▷ Col (input_object) singlechannelimage(-array) object : real
  Vector component in the column direction.
▷ VectorField (output_object) image(-array) object : vector_field
  Displacement vector field.
Type (input_control) .................................................. string  ~ string
Semantic kind of the vector field.
Default value: 'vector_field_relative'
List of values: Type ∈ ['vector_field_relative', 'vector_field_absolute']

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

vector_field_to_real

Module

vector_field_to_real ( VectorField : Row, Col : : )

Convert a vector field image into two real-valued images.

vector_field_to_real converts the vector field image VectorField into two real-valued images Row and Col. The output images contain the vector components in the row and column direction, respectively.

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Inspection

16.1 Bead Inspection

```
apply_bead_inspection_model ( Image : LeftContour, RightContour,
    ErrorSegment : BeadInspectionModel : ErrorType )
```

Inspect beads in an image, as defined by the bead inspection model.

The operator `apply_bead_inspection_model` applies the bead inspection model `BeadInspectionModel` to the input `Image`. The output parameter `ErrorSegment` indicates the positions of detected errors. The parameter `ErrorType` indicates the type of the detected errors. For more details on the possible errors, refer to the parameters’ description and figures in `create_bead_inspection_model`. The value of 'ErrorType' can be:

'no bead': No bead could be detected at this position.

'incorrect position': The center of the bead found at this position is further away from the contour than allowed by `PositionTolerance`.

'too thin': The bead is thinner than allowed by `TargetThickness` and `ThicknessTolerance`.

'too thick': The bead is thicker than allowed by `TargetThickness` and `ThicknessTolerance`.

Values of the generic parameters set through `create_bead_inspection_model` or `set_bead_inspection_param` highly affect the inspection results of the same model. For more details on those parameters, please refer to `create_bead_inspection_model`.

---

---

The operator `apply_bead_inspection_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.
Multithreading type: reentrant (runs in parallel with non-exclusive operators).
Multithreading scope: global (may be called from any thread).
Processed without parallelization.

This operator modifies the state of the following input parameter:

• BeadInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

clear_bead_inspection_model ( : : BeadInspectionModel : )

Delete the bead inspection model and free the allocated memory.

The operator clear_bead_inspection_model deletes a bead inspection model that was created by create_bead_inspection_model. All memory used by the model is freed. The handle of the model is passed in BeadInspectionModel. It is invalid after the operator call.

Parameters

▷ BeadInspectionModel (input_control) ................. bead_inspection_model ~ handle

Handle of the bead inspection model.

Result

The operator clear_bead_inspection_model returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred bead inspection model can be freed correctly. Otherwise, an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• BeadInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
**create_bead_inspection_model** (BeadContour : TargetThickness,
ThicknessTolerance, PositionTolerance, Polarity, GenParamName,
GenParamValue : BeadInspectionModel)

Create a model to inspect beads or adhesive in images.

create_bead_inspection_model creates a model to inspect beads or adhesive in images.

**The basic principle of bead inspection**

The bead inspection operators enable the user to define a reference contour that indicates the position and shape of a bead or adhesive on a certain product. Images of such products can then be inspected to verify that a bead or adhesive exists at the positions defined by the contour and that it is of acceptable thickness. The images must already be aligned with the given contour.

The operator create_bead_inspection_model returns a handle to the bead inspection model in BeadInspectionModel, which can later be used to perform other operations related to bead inspection. These operations include the modification of the bead inspection model parameters and performing the inspection on input images as defined by the model.

**Providing the model contour**

In order to inspect beads, a contour serving as the model for the bead must be provided in BeadContour. Such a contour can be generated, e.g., by using the operators gen_contour_polygon_xld or gen_contour_nurbs_xld. The contour must be defined to be aligned to the beads in the input images. To achieve this, the user can draw the XLD directly on a reference image in the graphics window (with draw_polygon or draw_nurbs). To inspect beads consisting of multiple parts, multiple models must be created.

**Mandatory parameters**

In order to inspect beads, the following parameters must be set:

**TargetThickness**: defines the optimal bead thickness in pixels.

**ThicknessTolerance**: determines the acceptable thickness deviation from the TargetThickness.

**PositionTolerance**: specifies the allowed position deviation from the defined contour.

**Polarity**: indicates whether to search for beads or adhesive.

**GenParamName** and **GenParamValue**: allow for additional parameters and values to be specified for the inspection model.

The mandatory parameters for a bead inspection model

In order to inspect beads, the following parameters must be set:

**TargetThickness**: defines the optimal bead thickness in pixels.
**ThicknessTolerance**: defines the tolerance to the bead’s thickness in pixels. The bead is accepted if its thickness is within the range:

\[
\text{TargetThickness} - \text{ThicknessTolerance}, \text{TargetThickness} + \text{ThicknessTolerance}
\]

**PositionTolerance**: defines the tolerance to the bead’s position in pixels. The ‘bead position’ is the center of the detected bead. The bead is accepted if the distance between its center and the contour’s position is less than the PositionTolerance.

**Polarity**: defines the polarity of the bead in the images to inspect. ‘light’ if the bead is lighter than its background, ‘dark’ otherwise.

### Edge extraction parameters

Bead inspection relies on edge extraction to identify the edges of beads. Accordingly, correct initialization of the measure_pos parameters helps improve bead inspection results. In particular, the following 2 parameters are included as generic parameters in the bead inspection model:

- ‘sigma’: As defined in measure_pos, ‘sigma’ is the standard deviation of the Gaussian smoothing kernel. The value of ‘sigma’ depends on the quality of the images to be inspected, namely on the amount of noise. ‘sigma’ is set to 2.0 by default.
- ‘threshold’: As defined in measure_pos, ‘threshold’ sets the minimum edge amplitude to be extracted. Setting a higher value for ‘threshold’ helps to avoid the extraction of noise edges and select salient edges. ‘threshold’ cannot be less than 1 and is set to 30 by default.

The Measure Assistant can be used to find suitable values for these two parameters.

---

**Parameters**

- **BeadContour** (input_object): XLD contour specifying the expected bead’s shape and position.
- **TargetThickness** (input_control): Optimal bead thickness.
  - Default value: 50
  - Typical range of values: 5 ≤ TargetThickness
- **ThicknessTolerance** (input_control): Tolerance of bead’s thickness with respect to TargetThickness.
  - Default value: 15
  - Typical range of values: 0 ≤ ThicknessTolerance
- **PositionTolerance** (input_control): Tolerance of the bead’s center position.
  - Default value: 15
  - Typical range of values: 0 ≤ PositionTolerance
- **Polarity** (input_control): The bead’s polarity.
  - Default value: 'light'
  - List of values: Polarity ∈ {'light', 'dark'}
- **GenParamName** (input_control): Names of the generic parameters that can be adjusted for the bead inspection model.
  - Default value: []
  - List of values: GenParamName ∈ {'sigma', 'threshold'}
- **GenParamValue** (input_control): Values of the generic parameters that can be adjusted for the bead inspection model.
  - Default value: []
  - Suggested values: GenParamValue ∈ {0.6, 1.0, 4.0, 5.0, 10.0, 50.0}
- **BeadInspectionModel** (output_control): Handle for using and accessing the bead inspection model.

---

**Example**

* Read the image of the bead to be inspected.
  read_image (Image, 'bead/adhesive_bead_01')
* Define the reference path of the adhesive beads.
16.1. BEAD INSPECTION

**gen_contour_nurbs_xld** (ContourRef, \
[610.974, 533.443, 461.763, 393.009, 330.106, 287.683, \n270.129, 265.74, 265.74, 300.849, 331.569, 376.917, \n438.357, 489.557, 539.294], \n[418.581, 424.27, 439.441, 473.574, 526.67, 574.078, \n644.241, 708.715, 765.604, 818.7, 866.107, 915.411, \n966.611, 998.848, 993.159], \n'auto', \n[15, 15, 15, 15, 15, 15, 15, 15, 15, 15, 15, 15, 15, 15], \n3, 1, 5)

* Create the bead inspection model, identifying the bead's parameters
create_bead_inspection_model (ContourRef, 14, 7, 30, 'dark', [], [], BeadInspectionModel)

* Apply the bead inspection model to the image
apply_bead_inspection_model (Image, LeftContour, RightContour, \
ErrorSegment, BeadInspectionModel, ErrorType)

---

**Result**

The operator `create_bead_inspection_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- BeadInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**get_bead_inspection_param** ( :: BeadInspectionModel, 
GenParamName : GenParamValue )

Get the value of a parameter in a specific bead inspection model.

The operator `get_bead_inspection_param` is used to query the values of the different parameters of a bead inspection model. The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. All these parameters can be set and changed at any time with the operator `set_bead_inspection_param`. Multiple parameters can be queried with a single call to `get_bead_inspection_param`.

---

HALCON 20.05.0.0
The parameters that can be queried are 'target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma' and 'threshold'. Only the model's contour cannot be queried. Refer to set_bead_inspection_param and create_bead_inspection_model for a detailed description of all supported parameters.

The operator get_bead_inspection_param returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

See also
create_bead_inspection_model, set_bead_inspection_param

2D Metrology

set_bead_inspection_param ( : : BeadInspectionModel, GenParamName, GenParamValue : )

Set parameters of the bead inspection model.

The operator set_bead_inspection_param is used to set parameters of a bead inspection model in order to adapt it to a particular inspection task. All parameters except for the model's contour can be set with this operator. A new bead inspection model should be used when a new contour is introduced. The current values of all parameters can be queried with the operator get_bead_inspection_param.

Parameters that can be set

The following parameters are essential and inspection model specific. It is vital for the inspection’s success to identify accurate values for those parameters:

'target_thickness': sets the TargetThickness.
'thickness_tolerance': sets the ThicknessTolerance.
'position_tolerance': sets the PositionTolerance.
'polarity': sets the bead's Polarity.
'sigma'
'threshold'

For more details, refer to the parameters’ description in create_bead_inspection_model.
16.2 OCV

**Parameters**

- **BeadInspectionModel** (input_control) .................................. bead_inspection_model \(\sim\) handle
  Handle of the bead inspection model.
- **GenParamName** (input_control) ............................................. attribute.name(-array) \(\sim\) string
  Name of the model parameter that shall be adjusted for the specified bead inspection model.
  **Default value:** 'target_thickness'
  **List of values:** GenParamName \(\in\) ['target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma', 'threshold']
- **GenParamValue** (input_control) ........................................... attribute.value(-array) \(\sim\) string / integer / real
  Value of the model parameter that shall be adjusted for the specified bead inspection model.
  **Default value:** 40
  **Suggested values:** GenParamValue \(\in\) {40, 10, 15, 0.6, 1.0, 4.0, 5.0, 'light', 'dark'}

**Result**

The operator `set_bead_inspection_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

### 16.2 OCV

**close_ocv** ( : : OCVHandle : )

Clear an OCV tool.

`close_ocv` closes an open OCV tool and frees the memory. The OCV tool has been created using `create_ocv_proj` or `read_ocv`. The handle is after this call no longer valid.

**Parameters**

- **OCVHandle** (input_control) ............................................... ocv \(\sim\) handle
  Handle of the OCV tool which has to be freed.

**Example**
read_ocv("ocv_file", &ocv_handle);
for (i=0; i<1000; i++)
{
    grab_image_async(&Image, fg_handle, -1);
    reduce_domain(Image, ROI, &Pattern);
    do_ocv_simple(Pattern, ocv_handle, "A",
        "true", "true", "false", "true", 10,
        &Quality);
}
close_ocv(ocv_handle);

Result

close_ocv returns 2 (H_MSG_TRUE), if the handle is valid. Otherwise, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:
• OCVHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

See also

close_ocr

Module

OCR/OCV

---

**create_ocv_proj** ( : : PatternNames : OCVHandle )

Create a new OCV tool based on gray value projections.

create_ocv_proj creates a new OCV tool. This tool will be used to train good-patterns for the optical character verification. The training is done using the operator traind_ocv_proj. Thus traind_ocv_proj is normally called after create_ocv_proj.

The pattern comparison is based on the gray projections: For every training pattern the horizontal and vertical gray projections are calculated by summing up the gray values along the rows and columns inside the region of the pattern. This operation is applied to the training patterns and the test patterns. For the training patterns the result is stored inside the OCV tool to save runtime while comparing patterns. The OCV is done by comparing the corresponding projections. The Quality is the similarity of the projections.

Input for create_ocv_proj are the names of the patterns (PatternNames) which have to be trained. The number and the names can be chosen arbitrary. In most case only one pattern will be trained, thus only one name has to be specified. The names will be used when doing the OCV (do_ocv_simple). It is possible to specify more names than actually used. These might be trained later.

To close the OCV tool, i.e. to free the memory, the operator close_ocv is called.

Parameters

- **PatternNames** (input_control) .................................................. string(-array) \~ string
  List of names for patterns to be trained.
  Default value: 'a'
- **OCVHandle** (output_control) .................................................. ocv \~ handle
  Handle of the created OCV tool.
Example

```c
create_ocv_proj("A", &ocv_handle);
draw_region(&ROI, window_handle);
reduce_domain(Image, ROI, &Sample);
traind_ocv_proj(Sample, ocv_handle, "A", "single");
```

Result

`create_ocv_proj` returns 2 (`H_MSG_TRUE`), if the parameters are correct. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`traind_ocv_proj, write_ocv, close_ocv`

Alternatives

`create_ocr_class_box`

Module

OCR/OCV

deserialize_ocv ( : : SerializedItemHandle : : OCVHandle )

Deserialize a serialized OCV tool.

`deserialize_ocv` deserializes an OCV tool, that was serialized by `serialize_ocv` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCV tool is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCV tool with the handle `OCVHandle`. After deserializing the tool the training can be completed for those patterns which have not been trained so far. Otherwise, a pattern comparison can be applied directly by calling `do_ocv_simple`.

Parameters

- `SerializedItemHandle` (input_control)  ......................... serialized_item  ~ handle Handle of the serialized item.
- `OCVHandle` (output_control)  .............................................. ocv  ~ handle Handle of the OCV tool.

Result

If the parameters are valid, the operator `deserialize_ocv` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
Possible Predecessors
fread_serialized_item, receive_serialized_item, serialize_ocv

Possible Successors
do_ocv_simple, close_ocv

Module

do_ocv_simple ( Pattern : : OCVHandle, PatternName, AdaptPos, AdaptSize, AdaptAngle, AdaptGray, Threshold : Quality )

Verification of a pattern using an OCV tool.
do_ocv_simple evaluates the pattern in (Pattern). Before the evaluation the good-pattern has to be trained by using the operator traind_ocv_proj. Both patterns should have roughly the same (relative) extent and shape. To specify which of the trained patterns is used as reference its name is specified in PatternName. The next four parameters influence the automatic adaption: AdaptPos and AdaptSize refer to the geometry of the pattern. AdaptPos specifies whether a shift of the position will be adapted automatically. AdaptSize is used to adapt to changes in the size of the pattern. AdaptAngle is not implemented. The parameter AdaptGray controls the adaption to changes of the grayvalues. This comprises additive and multiplicative changes of the intensity.

The parameter Threshold specifies the minimum difference of the gray values to be treated as an error. In this case the percentage of wrong pixels is returned. If the value is below 0 the sum of all errors normalized with respect to the size is returned.

The result of the operator is the Quality of the pattern with a value between 0 and 1. The value 1 corresponds to a pattern with no faults. The value 0 corresponds to a very big fault.

Parameters

- Pattern (input_object) singlechannelimage(-array) -> object : byte
  Characters to be verified.
- OCVHandle (input_control) ocv -> handle
  Handle of the OCV tool.
- PatternName (input_control) string(-array) -> string
  Name of the character.
    Default value: 'a'
- AdaptPos (input_control) string -> string
  Adaption to vertical and horizontal translation.
    Default value: 'true'
    List of values: AdaptPos ∈ ['true', 'false']
- AdaptSize (input_control) string -> string
  Adaption to vertical and horizontal scaling of the size.
    Default value: 'true'
    List of values: AdaptSize ∈ ['true', 'false']
- AdaptAngle (input_control) string -> string
  Adaption to changes of the orientation (not implemented).
    Default value: 'false'
    List of values: AdaptAngle ∈ ['false']
- AdaptGray (input_control) string -> string
  Adaption to additive and scaling gray value changes.
    Default value: 'true'
    List of values: AdaptGray ∈ ['true', 'false']
- Threshold (input_control) number -> real
  Minimum difference between objects.
    Default value: 10
    Suggested values: Threshold ∈ [-1.0, 0.0, 1.0, 5.0, 10.0, 15.0, 20.0, 30.0, 40.0, 50.0, 60.0, 80.0, 100.0, 150.0]
16.2. OCV

▌ Quality (output_control) ................................................................. real(-array) \( \sim \) real
Evaluation of the character.

Typical range of values: \( 0.0 \leq \text{Quality} \leq 1.0 \)

do_ocv_simple returns 2 (H_MSG_TRUE), if the handle and the characters are correct. Otherwise, an exception is raised.

Result

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

create_ocv_proj

Module

OCR/OCV

▌ read_ocv ( : : FileName : OCVHandle )

Reading an OCV tool from file.

read_ocv reads an OCV tool from file. The tool will contain the same information that it contained when saving it with write_ocv. After reading the tool the training can be completed for those patterns which have not been trained so far. Otherwise a pattern comparison can be applied directly by calling do_ocv_simple.

As extension ‘.ocv’ is used. If this extension is not given with the file name it will be added automatically.

Parameters

▌ FileName (input_control) ............................................................. filename.read \( \sim \) string
Name of the file which has to be read.
Default value: ‘test_ocv’
File extension: .ocv

▌ OCVHandle (output_control) ....................................................... ocv \( \sim \) handle
Handle of read OCV tool.

Example

read_ocv("ocv_file",&ocv_handle);
for (i=0; i<1000; i++)
{
    grab_image_async(&Image,fg_handle,-1);
    reduce_domain(Image,ROI,&Pattern);
    do_ocv_simple(Pattern,ocv_handle,"A",
        "true","true","false","true",10,
        &Quality);
}
close_ocv(ocv_handle);

Result

read_ocv returns 2 (H_MSG_TRUE), if the file is correct. Otherwise, an exception is raised.

Parallelization

HALCON 20.05.0.0
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module
OCR/OCV

serialize_ocv ( : : OCVHandle : SerializedItemHandle )

Serialize an OCV tool.

serialize_ocv serializes the data of an OCV tool (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocv is converted to a serialized item. The OCV tool is defined by the handle OCVHandle. The serialized OCV tool is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocv.

Parameters
¬ OCVHandle (input_control) ........................................... ocv \(\sim\) handle
Handle of the OCV tool.
¬ SerializedItemHandle (output_control) ..........................serialized_item \(\sim\) handle
Handle of the serialized item.

Result
If the parameters are valid, the operator serialize_ocv returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
OCR/OCV

traind_ocv_proj ( Pattern : : OCVHandle, Name, Mode : )

Training of an OCV tool.

traind_ocv_proj trains patterns for an OCV tool that has been created using the operators create_ocv_proj or read_ocv. For this training one or multiple patterns are provided to the system. Such a pattern consists of an image with a reduced domain (ROI) for the area of the pattern. Note that the pattern should
not only contain foreground pixels (e.g., dark pixels of a character) but also background pixels. This can be implemented e.g., by the smallest surrounding rectangle of the pattern. Without this context, an evaluation of the pattern is not possible.

If more than one pattern has to be trained, this can be achieved by multiple calls (one for each pattern) or by calling traind_ocv_proj once with all patterns and a tuple of the corresponding names. The result will be in both cases the same. However, using multiple calls will normally result in a longer execution time than using one call with all patterns.

**Parameters**

- **Pattern**: (input_object) singlechannelimage(-array) \(\sim\) object: byte
  - Pattern to be trained.

- **OCVHandle**: (input_control) ocv: handle
  - Handle of the OCV tool to be trained.

- **Name**: (input_control) string(-array)
  - Name(s) of the object(s) to analyse.
  - Default value: 'a'

- **Mode**: (input_control) string
  - Mode for training (only one mode implemented).
  - Default value: 'single'
  - List of values: Mode \(\in\) {'single'}

**Example**

```c
create_ocv_proj("A", &ocv_handle);
draw_region(&ROI, window_handle);
reduce_domain(Image, ROI, &Sample);
traind_ocv_proj(Sample, ocv_handle, "A", "single");
```

**Result**

traind_ocv_proj returns 2 (H_MSG_TRUE), if the handle and the training pattern(s) are correct. Otherwise, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **OCVHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

**Module**

OCR/OCV

```
write_ocv ( : : OCVHandle, FileName : )
```

Saving an OCV tool to file.
write_ocv writes an OCV tool to file. This can be used to save the result of a training (traind_ocv_proj). The whole information contained in the OCV tool is stored in the file. The file can be reloaded afterwards using the operator read_ocv.

As file extension `.ocv` is used. If this extension is not given with the file name, it will be added automatically.

Parameters

- **OCVHandle** (input_control)  ~ handle
  Handle of the OCV tool to be written.

- **FileName** (input_control)  ~ string
  Name of the file where the tool has to be saved.
  Default value: `test_ocv`
  File extension: `.ocv`

Result

write_ocv returns 2 (H_MSG_TRUE), if the data is correct and the file can be written. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

16.3 Structured Light

This chapter describes operators for using structured light.

Concept of Structured Light

The basic concept behind structured light is the display of known patterns onto a display or projector. The way those patterns appear in the scene after hitting surfaces helps to further analyze the surfaces.

To use structured light, a model must first be created using `create_structured_light_model`. The model type is specified in `ModelType`. Currently, only the model type 'deflectometry' is supported. Deflectometry is the procedure of analyzing the reflections of known patterns from specular or semi-specular surfaces. In such a setup, for every pattern image projected on the screen, a camera image of the reflection is acquired. Deformations of the pattern in the camera image imply a defect on the specular surface.

In the following, the steps that are required to perform defect detection on specular surfaces are described briefly.

Create a structured light model: In the first step, a structured light model is created with

- `create_structured_light_model`

or read with

- `read_structured_light_model`. 
16.3. STRUCTURED LIGHT

Set the model parameters: The different structured light model parameters can then be set with set_structured_light_model_param or queried with get_structured_light_model_param. The pattern parameters 'pattern_width', 'pattern_height', 'pattern_orientation', and 'pattern_type' specify along with the stripe parameters 'min_stripe_width' and 'single_stripe_width' the specifications of the pattern images to be generated and projected onto the specular surface. Finally, the 'persistence' parameter can be enabled to debug intermediate results.

Generate the pattern images: The pattern images are to be generated with gen_structured_light_pattern after setting all relevant parameters. Please ensure that the output images are as needed in the particular setup.

Project the patterns and acquire the camera images: At this stage, the pattern images are shown on the display and reflected by the specular surface. The respective reflected image is acquired by the camera for each pattern image.

Decode the acquired images: The acquired CameraImages can be decoded with decode_structured_light_pattern. Upon calling this operator, the correspondence images are created and stored in the model StructuredLightModel.

Get the results: Now the decoded 'correspondence_image', as well as other results can be queried with get_structured_light_object. The 'defect_image' can be generated and queried with get_structured_light_object. For more details of the different objects that can be queried, please refer to the operator’s documentation.

Further operators

The structured light model offers various other operators that help access and update the various parameters of the model.

The operator write_structured_light_model enables writing the structured light model to a file. Please note that previously generated pattern images are not written in this file. A structured light model file can be read using read_structured_light_model.

Furthermore, it is possible to serialize and deserialize the structured light model using serialize_structured_light_model and deserialize_structured_light_model.

Further Information

See also the “Solution Guide Basics” for further details.

`clear_structured_light_model` ( : : StructuredLightModel : )

Clear a structured light model and free the allocated memory.

The operator clear_structured_light_model deletes a structured light model that was created by create_structured_light_model. All memory used by the model is freed. The handle of the model is passed in StructuredLightModel. It is invalid after the operator call.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

Parameters

- **StructuredLightModel**: Handle of the structured light model.

Result

The operator clear_structured_light_model returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred structured light model can be freed correctly. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_structured_light_model

3D Metrology

create_structured_light_model (ModelType : StructuredLightModel)

Create a structured light model.

create_structured_light_model creates a new structured light model of type ModelType. Currently, only the type 'deflectometry' is supported.

The parameters of the structured light model can be queried with get_structured_light_model_param and manipulated by calls to set_structured_light_model_param.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

Parameters

- ModelType (input_control) string -> string
  The type of the created structured light model.
  Default value: 'deflectometry'

- StructuredLightModel (output_control) structured_light_model -> handle
  Handle for using and accessing the structured light model.

Example

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)

Result

The operator create_structured_light_model returns the value 2 (H_MSG_TRUE) if the structured light model can be allocated correctly. Otherwise, an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_structured_light_model_param, get_structured_light_model_param

3D Metrology

Decode the camera images acquired with a structured light setup.

decode_structured_light_pattern decodes the camera images \( \texttt{CameraImages} \) that have been previously acquired with a structured light setup. The correspondence images and other intermediate results that are created by the decoding process are stored in the model \( \texttt{StructuredLightModel} \) and can be accessed afterwards using the operator \( \texttt{get_structured_light_object} \).

In the following, the decoding process is explained in detail:

As mentioned in \( \texttt{gen_structured_light_pattern} \) the first purpose is to find out whether a pixel is in a region where a light stripe is reflected or where a dark stripe is reflected. To simplify this decision process the normalization images are used and a locally varying threshold is determined that is able to cope with objects of varying reflectance and lighting conditions. During the decoding of the acquired camera images all Gray code images are then compared with the previously calculated threshold. A pixel within the image is classified as bright if its gray value is greater or equal this threshold.

Furthermore, the pattern region is segmented during the decoding process. The segmentation is controlled by the parameter ‘\( \texttt{min\_gray\_difference} \)’ (see \( \texttt{set_structured_light_model_param} \)).

Assuming that \( n \) Gray code images have been processed, we get a \( n \)-bit binary code for each pixel. From this sequence the row and column coordinates up to ‘\( \texttt{min\_stripe\_width}/2 \)’ of the monitor can be derived.

If the \( \texttt{StructuredLightModel} \) is a hybrid system consisting not only of Gray code images but also of phase shift images (see \( \texttt{gen_structured_light_pattern} \)), the next step is to decode the latter ones. The result is a subpixel-precise correspondence image between the monitor coordinates and the camera coordinates that contains the information which camera pixel observes which monitor pixel.

If the ‘\( \texttt{pattern\_type} \)’ of the \( \texttt{StructuredLightModel} \) is set to ‘\( \texttt{single\_stripe} \)’, the first step in the decoding process is to decide which single stripe shed its light on a camera pixel. The Gray code sequence and phase are then used to refine the position within the found single stripe.

In real world setups it may occur that the detected Gray code sequence of a pixel is wrong. This can then lead to values in the correspondence images which represent monitor rows or columns larger than the monitor width and height. To avoid these problems, the last step of the decoding process is to remove these values from the correspondence images.

---

**Parameters**

- \( \texttt{CameraImages} \) (input_object) ......................... (multichannel-image-array) ~ object: byte / uint2
  Acquired camera images.

- \( \texttt{StructuredLightModel} \) (input_control) ......................... structured_light_model ~ handle
  Handle of the structured light model.

---

**Example**

* Create the model
  \[ \texttt{create_structured_light_model ('deflectometry', StructuredLightModel)} \]
* Set the size of the monitor
  \[ \texttt{set_structured_light_model_param (StructuredLightModel, \ 'pattern\_width', 1600)} \]
  \[ \texttt{set_structured_light_model_param (StructuredLightModel, \ 'pattern\_height', 1200)} \]
* Set the smallest width of the stripes in the pattern
  \[ \texttt{set_structured_light_model_param (StructuredLightModel, \ 'min\_stripe\_width', 8)} \]
* Generate the patterns to project
  \[ \texttt{gen_structured_light_pattern (PatternImages, StructuredLightModel)} \]
* Set the expected black/white contrast in the region of interest
  \[ \texttt{set_structured_light_model_param (StructuredLightModel, \ 'min\_gray\_difference', 70)} \]
* Decode the camera images
  \[ \texttt{decode_structured_light_pattern (CameraImages, StructuredLightModel)} \]
* Get the computed correspondences and defects

---
get_structured_light_object (CorrespondenceImages, StructuredLightModel, 'correspondence_image')
set_structured_light_model_param (StructuredLightModel, 'derivative_sigma', Sigma)
get_structured_light_object (DefectImage, StructuredLightModel, 'defect_image')

The operator `decode_structured_light_pattern` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**deserialize_structured_light_model**

```c
: : : SerializedItemHandle : StructuredLightModel
```

**Deserialize a structured light model.**

deserialize_structured_light_model deserializes a structured light model that was serialized by `serialize_structured_light_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized structured light model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created structured light model with the handle `StructuredLightModel`.

---

**Parameters**

- **SerializedItemHandle** (input_control) .......... serialized_item ~ handle
  Handle of the serialized item.
- **StructuredLightModel** (output_control) ........... structured_light_model ~ handle
  Handle of the structured light model.

---

**Example**

* Deserialize the model
  `deserialize_structured_light_model (SerializedItemHandle, StructuredLightModel)`

* Get a previously decoded result
  `get_structured_light_object (CorrespondenceImages, StructuredLightModel, 'correspondence_image')`
* Decode new camera images
  `decode_structured_light_pattern(CameraImages, StructuredLightModel)`
* Get the decoded result
  `get_structured_light_object(CorrespondenceImagesNew, StructuredLightModel, 'correspondence_image')`

---

**Result**

The operator `deserialize_structured_light_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

```plaintext

gen_structured_light_pattern ( )

: PatternImages : StructuredLightModel : )
```

Generate the pattern images to be displayed in a structured light setup.

`gen_structured_light_pattern` generates the pattern images that need to be displayed in a structured light setup. Several parameters such as the width and height of the images, the pattern type and the minimal stripe width need to be set in advance in the model `StructuredLightModel` using `set_structured_light_model_param`. Dependent on the set parameters of the `StructuredLightModel`, the number and the appearance of the pattern images vary.

In general, the pattern images can be divided into four groups of images:

- Normalization images
- Gray code images
- Phase shift images
- Single stripe images

**General information about the image types**

**Normalization images:**

Decoding of Gray code images relies upon being able to know whether a pixel is in a region where a light stripe is reflected or where a dark stripe is reflected. To allow a robust decoding even for large variations in the surface reflectance, normalization images are used to simplify the process of identifying light and dark regions. The simplest but in most cases also sufficient approach is to generate one entirely black and one entirely white image. During the decoding of the acquired camera images (see `decode_structured_light_pattern`) all Gray
code images are then compared with the mean of the dark and the bright image and a pixel within the image is classified as bright if its gray value is greater or equal the previously calculated mean.

Another approach is to use the Gray code images as explained in the next section and generate an inverted version of these images. A pixel is then classified as light, if its gray value in the first image is brighter than the gray value of the inverted version.

**Gray code images:**

Before performing any practical task such as detecting defects, the first step in any structured light measurement process is to find a mapping between the pixel plane of the camera and the pixel plane of the monitor. This can be achieved by displaying a series of images that uniquely encode the rows and columns of the monitor. Since Gray code images have some advantages compared to other pattern types, they are typically used for the encoding. An example of a series of vertical and horizontal Gray code images can be seen in the subsequent figure.

![Image series of vertical and horizontal Gray code images as generated by gen_structured_light_pattern. The patterns are typically displayed on the monitor from the coarsest pattern to the finest one while the stripe width is halved at each level.](image)

Although using Gray code images is a very simple, yet suitable approach, it comes with certain limitations. One drawback is that often many Gray code images are required to achieve a spatial resolution sufficient for practical applications. However, with increasingly finer resolution of the stripes, a correct decoding becomes harder and harder because of blurring effects introduced by the optics involved in the measurement process. To overcome these limitations, the third group of pattern images (phase shift images) can be generated.

**Phase shift images:**

Phase shift images usually use periodic patterns such as sine or cosine waves to reconstruct the phase and in combination with Gray code images the correspondences between the monitor and the camera coordinates. To allow a decoding that is robust despite variations in the surface reflectance and has a relaxed noise influence, four phase shift images per orientation (vertical or horizontal) are generated. Each image is a cosine wave with phase shifts of $\frac{k\pi}{2}$, where $k = 0, \ldots, 3$.

![Image series of vertical and horizontal phase shift images as generated by gen_structured_light_pattern.](image)

The main advantage of using phase shift images, is that in contrast to Gray code images subpixel-precise correspondences between the monitor and the camera coordinates can be calculated. Since the images are periodic, the
encoding is unique up to integer multiples of the period length. In order to achieve a unique encoding over the entire image, the combination with the Gray code image is necessary.

**Single stripe images:**
Single stripe images are dark with one bright stripe. The bright stripe is shifted over the images such that each monitor pixel is contained in exactly one stripe. To decide which bright stripe is reflected in the area observed by a camera pixel, the brightest pixel value within the sequence of single stripe images is chosen during decoding. This allows a decoding that is robust despite variations in the surface reflectance.

The Gray code sequence and phase are then used to refine the position within the found single stripe. Thus, while additional single stripe images are generated, the number of created Gray code images will typically decrease slightly.

**Information about the generation of the image types**

**Generating the normalization images:**
As mentioned above, HALCON offers two different kinds of normalization images. By default, the 'normalization' method is set to 'global' which results in the generation of an entirely black and an entirely white image. To change the method such that each Gray code is additionally inverted, `set_structured_light_model_param` has to be called using the method 'inverted_pattern'.

The main advantage of using a global normalization is that the number of images is significantly smaller while simultaneously providing satisfying results. Only in cases of partially specular surfaces, the other method might be more robust and should be chosen if the global normalization leads to wrong decoding results.

**Generating the Gray code images:**
The size, the number and the appearance of the Gray code images is dependent on the following parameters (see `set_structured_light_model_param`): 'pattern_width', 'pattern_height', 'min_stripe_width' and 'pattern_orientation'.

Image series of vertical and horizontal single stripe images as generated by `gen_structured_light_pattern` for 'pattern_type' set to 'single_stripe'.

Image series of vertical and horizontal Gray code images as generated by `gen_structured_light_pattern` for 'pattern_type' set to 'single_stripe'.

HALCON 20.05.0.0
The first two parameters determine the size of the generated Gray code images and should usually be set to the size of the monitor that is used to display the pattern images. The parameter 'min_stripe_width' sets the width (in pixels) of the finest stripe of the pattern images that are generated. Additionally, all three parameters have a major influence on the number of created Gray code images.

Let \( \text{max\_stripe\_width} = 2^{\lceil \log_2(\text{pattern\_width}) \rceil} \) be the maximum stripe width in vertical direction and \( \text{max\_stripe\_width} = 2^{\lceil \log_2(\text{pattern\_height}) \rceil} \) be the maximum stripe width in horizontal direction. Then the number of Gray code images \( \text{num\_images} \) with stripes oriented in one of the two directions (either horizontal or vertical) is given by

\[
\text{num\_images} = \lceil \log_2(2 \cdot \text{max\_stripe\_width}/\text{min\_stripe\_width}) \rceil
\]

The parameter 'pattern\_orientation' sets the orientation of the Gray code (and phase shift) images that are generated. By default, images with vertical stripes as well as images with horizontal stripes are created. It is also possible to generate images with stripes having only one of the two directions. However, this is not recommended, because changes in the surface can then only be detected in one direction. Solely, if changes on the surface should be ignored or if defects are to be expected in only one direction, this parameter should be changed using `set_structured_light_model_param`.

Generating the phase shift images:
Since phase shift images are suitable to overcome the practical limitations of Gray code images their generation is recommended and enabled by default.

In case that the accuracy using Gray code images only is sufficient, the creation of phase shift images can be deactivated using `set_structured_light_model_param` by setting the 'pattern\_type' to the value 'gray\_code'.

Generating the single stripe images:
In case that using Gray code and phase shift images only is not robust enough (this might happen, for example, on semi-specular surfaces), the creation of single stripe images can be activated using `set_structured_light_model_param` by setting the 'pattern\_type' to the value 'single\_stripe'.

The number and the appearance of the single stripe images depends on the parameter 'single\_stripe\_width' which sets the width in pixels (see `set_structured_light_model_param`).

While additional single stripe images are generated, the number of created Gray code images will typically decrease slightly. To calculate the number of Gray code images, 'max\_stripe\_width' is replaced by 'single\_stripe\_width' in the formula above.

The use of these images is described in the introduction to the chapter Inspection / Structured Light.

---

### Parameters

- **PatternImages** (output_object) ......................... (multichannel-)image(-array) \( \sim \) object : byte
  Generated pattern images.

- **StructuredLightModel** (input_control) ......................... structured_light_model \( \sim \) handle
  Handle of the structured light model.

---

* Create the model
  `create_structured_light_model ('deflectometry', StructuredLightModel)`

* Set the size of the monitor
  `set_structured_light_model_param (StructuredLightModel, \`
  'pattern\_width', 1600)`

  `set_structured_light_model_param (StructuredLightModel, \`
  'pattern\_height', 1200)`

* Set the smallest width of the stripes in the pattern
  `set_structured_light_model_param (StructuredLightModel, \`
  'min\_stripe\_width', 8)`

* Generate the patterns to project
  `gen_structured_light_pattern (PatternImages, StructuredLightModel)`

* Decode the camera images
  `decode_structured_light_pattern (CameraImages, StructuredLightModel)`

---

16.3. STRUCTURED LIGHT

The operator `gen_structured_light_pattern` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- set_structured_light_model_param

Possible Successors

- decode_structured_light_pattern
- create_structured_light_model, get_structured_light_model_param, get_structured_light_object

See also

- create_structured_light_model
- get_structured_light_model_param
- get_structured_light_object

Module

3D Metrology

---

```hal
get_structured_light_model_param ( : : StructuredLightModel, GenParamName : GenParamValue )
```

Query parameters of a structured light model.

The operator `get_structured_light_model_param` is used to query the values of the different parameters of a structured light model (`StructuredLightModel`). The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. It is possible to query multiple parameters with a single call to `get_structured_light_model_param`. All parameters which can be manipulated by `set_structured_light_model_param` can be queried. Please refer to the documentation of `set_structured_light_model_param` for an explanation of the individual parameters.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

---

**Parameters**

- **StructuredLightModel** (input_control) .......... `structured_light_model` handle
  Handle of the structured light model.
- **GenParamName** (input_control) .......... `attribute.name(-array)` `string`
  Name of the queried model parameter.
  **Default value:** 'min_stripe_width'
  **List of values:** `GenParamName ∈ {'derivative_sigma', 'min_gray_difference', 'min_stripe_width', 'normalization', 'pattern_height', 'pattern_orientation', 'pattern_type', 'pattern_width', 'single_stripe_width', 'persistence'}`
- **GenParamValue** (output_control) .......... `attribute.value(-array)` `integer` / `real` / `string`
  Value of the queried model parameter.

---

**Example**

* Create the model
  `create_structured_light_model ('deflectometry', StructuredLightModel)`
* Get the default value
get_structured_light_model_param (StructuredLightModel, \  'min_stripe_width', Default)
* Set the value
set_structured_light_model_param (StructuredLightModel, \  'min_stripe_width', 64)
* Get the value
get_structured_light_model_param (StructuredLightModel, 'min_stripe_width', \  MinStripeWidth)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)

Result
The operator get_structured_light_model_param returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

set_structured_light_model_param

Module
3D Metrology

get_structured_light_object ( : Object : StructuredLightModel,  
    ObjectName : )

Get (intermediate) iconic results of a structured light model.

With the operator get_structured_light_object you can access and inspect (intermediate) iconic results of a structured light measurement setup that has already been decoded using decode_structured_light_pattern.

On the one hand, this is useful to query the results of the decoding process ('correspondence_image') together with further processed results i.e. the defect image ('defect_image'). On the other hand, get_structured_light_object is also useful for troubleshooting the decoding process. Note that to collect the intermediate results, the 'persistence' mode has to be enabled for the StructuredLightModel (see set_structured_light_model_param) before decoding the model.

Objects that can be accessed without persistence mode enabled:

'correspondence_image': Image that describes the correspondences between the monitor and the camera. If the decoding has been performed in vertical and horizontal direction, both correspondence images are returned in an array. Otherwise, only the image of the appropriate direction is returned.

'pattern_region': Segmented region in which the camera images have been decoded. This region is identical to the domain of the correspondence images.

'defect_image': Image that describes possible defects on the surface which reflects the projected patterns towards the camera. Basically, high gray values in the defect image indicate that the gradients of the correspondence images differ significantly from gradients in the neighborhood.

Objects that can be accessed only when in persistence mode:

If the decoding has been performed in vertical and horizontal direction, images of both directions are returned in an array. Otherwise, only the images of the appropriate direction are returned.
'binarized_image': Images of the Gray code sequence where white and black gray values indicate that the camera pixel observed reflections of white or black regions of the projected patterns. If 'normalization' was set to 'inverted_pattern' using set_structured_light_model_param, this refers to the first image of an inverted pair.

'decoded_phase_shift_image': Decoded phase shift images containing the phase or angle corresponding to the projected phase images. One phase period covers stripes in the projected pattern of an extent 'min_stripe_width'.

'decoded_single_stripe_image': Decoded single stripe image computed solely from the single stripe images. The correspondence image is a combination of this image with the Gray code and phase shift images, if 'pattern_type' is set to 'single_stripe'.

'gray_code_correspondence_image': Correspondence image computed solely from the Gray code images. If 'pattern_type' is set to 'gray_code_and_phase_shift', the actual correspondence image is a combination of this image with the decoded phase shift images. If 'pattern_type' is set to 'single_stripe', the actual correspondence image is a combination of this image with the decoded phase shift images and the decoded single stripe images.

Parameters

- **Object** (output_object) .......................................... (multichannel-)object(-array) $\rightsquigarrow$ object
  Iconic result.

- **StructuredLightModel** (input_control) .................. structured_light_model $\rightsquigarrow$ handle
  Handle of the structured light model.

- **ObjectName** (input_control) .............................. string(-array) $\rightsquigarrow$ string
  Name of the iconic result to be returned.

  **Default value:** 'correspondence_image'

  **Suggested values:** ObjectName $\in$ ['correspondence_image', 'pattern_region', 'decoded_single_stripe_image', 'binarized_image', 'decoded_phase_shift_image', 'gray_code_correspondence_image', 'defect_image']

Example

* Create the model
  create_structured_light_model ('deflectometry', StructuredLightModel)

* Generate the patterns to project
  gen_structured_light_pattern (PatternImages, StructuredLightModel)

* Decode the camera images
  decode_structured_light_pattern (CameraImages, StructuredLightModel)

* Get the computed correspondences and defects
  get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
   'correspondence_image')

  set_structured_light_model_param (StructuredLightModel, \
   'derivative_sigma', Sigma)

  get_structured_light_object (DefectImage, StructuredLightModel, \
   'defect_image')

Result

The operator get_structured_light_object returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_structured_light_model (
:

:

FileName :

StructuredLightModel )

Read a structured light model from a file.
read_structured_light_model reads the structured light model StructuredLightModel that has
been stored with write_structured_light_model. The default HALCON file extension for the structured
light model is ’hslm’.
It can be helpful to write a model after setting all the optimal parameters for a particular setup. The model can be
read later to easily regenerate pattern images. The objects already generated in the model before writing it can be
also revisited later after reading the model.
For an explanation of the concept of structured light and its supported applications, see the introduction of chapter
Inspection / Structured Light.
Parameters
. FileName (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . filename.read ; string
File name.
File extension: .hslm
. StructuredLightModel (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . structured_light_model ; handle
Handle of the structured light model.
Example
* Read the model
read_structured_light_model ('ExampleModel.hslm', StructuredLightModel)
* Get a previously decoded result
get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
'correspondence_image')
* Decode new camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the decoded result
get_structured_light_object (CorrespondenceImagesNew, StructuredLightModel, \
'correspondence_image')
Result
The operator read_structured_light_model returns the value 2 (H_MSG_TRUE) if the given parameters
are valid. Otherwise, an exception will be raised.
Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific
operators even though the handle is used as an input parameter by those operators.

serialize_structured_light_model ( :
    : : StructuredLightModel : SerializedItemHandle )

Serialize a structured light model.
serialize_structured_light_model serializes a structured light model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The structured light model is defined by the handle StructuredLightModel. The serialized structured light model is returned by the handleSerializedItemHandle and can be deserialized by deserialize_structured_light_model.

Parameters

▷ StructuredLightModel (input_control) ......................... structured_light_model ↦ handle
Handle of the structured light model.
▷ SerializedItemHandle (output_control) .......................... serialized_item ↦ handle
Handle of the serialized item.

Example

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Serialize the model
serialize_structured_light_model (StructuredLightModel, \SerializedItemHandle)

Result

The operator serialize_structured_light_model returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors

clear_structured_light_model, fwrite_serialized_item, send_serialized_item,

set_structured_light_model_param ( : : StructuredLightModel,
    GenParamName, GenParamValue : )

Set parameters of a structured light model.
The operator set_structured_light_model_param is used to manipulate the parameters of a structured light model StructuredLightModel. The current parameter settings can be queried with the operator get_structured_light_model_param.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

General parameters:
'persistence': Enables (GenParamValue='true') or disables (GenParamValue='false') the 'persistence' mode of the structured light model. When in persistence mode, the model stores intermediate results of the decoding, which can be inspected later by get_structured_light_object.

Note that the model might need significant memory space in this mode. Therefore, we recommend to enable this mode only during the setup and for debugging a structured light model setup.

If 'persistence' is changed, all results of the model are cleared.

Values: 'true', 'false', 1, 0
Default: 'false'

Parameters which influence the appearance of the generated pattern images:

'pattern_width': Sets the width of the pattern images that are generated while calling gen_structured_light_pattern. Usually, the value should be set to the width of the monitor that is used to display the pattern images.

The value of 'pattern_width' has to be larger than the value 'min_stripe_width'/2. In case that 'pattern_type' is 'single_stripe', it also has to be larger than 'single_stripe_width'/2.

If 'pattern_width' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 1
Default: 1024

'pattern_height': Sets the height of the pattern images that are generated while calling gen_structured_light_pattern. Usually, the value should be set to the height of the monitor that is used to display the pattern images.

The value of 'pattern_height' has to be larger than the value 'min_stripe_width'/2. In case that 'pattern_type' is 'single_stripe', it also has to be larger than 'single_stripe_width'/2.

If 'pattern_height' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 1
Default: 1024

'min_stripe_width': Sets the width (in pixels) of the finest stripe of the pattern images that are generated while calling gen_structured_light_pattern.

The value has to be a power of two. Furthermore, it has to be smaller or equal the minimum of the parameters 'pattern_width' and 'pattern_height' after rounding both up to their next power of two. In case that 'pattern_type' is 'single_stripe', it also has to be smaller or equal the 'single_stripe_width'.

If 'min_stripe_width' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 4 and a power of 2
Default: 32

'normalization': Sets the normalization mode of the structured light model. If the parameter is set to 'global', gen_structured_light_pattern generates two additional pattern images composed of a black and a white image. These images are then used in the decoding process to determine the actual pattern region. If instead, the value 'inverted_pattern' is chosen, each Gray code image is additionally inverted and the pattern region is segmented iteratively using the Gray code images and their inverted version.

If 'normalization' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: 'global', 'inverted_pattern'
Default: 'global'

'pattern_orientation': Sets the orientation of the pattern images that are generated while calling gen_structured_light_pattern. If the parameter is set to 'both', pattern images with vertical stripes as well as pattern images with horizontal stripes are created. For 'vertical' the pattern images consist of vertical stripes only, whereas for 'horizontal' only horizontal stripes are generated.
If ‘pattern_orientation’ is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: ‘both’, ‘vertical’, ‘horizontal’
Default: ‘both’

‘pattern_type’: Sets the type of the pattern images that are generated while calling gen_structured_light_pattern.

<table>
<thead>
<tr>
<th>‘pattern_type’</th>
<th>Generated Images</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘gray_code’</td>
<td>Gray code images</td>
</tr>
<tr>
<td>‘gray_code_and_phase_shift’</td>
<td>Gray code images and phase shift images</td>
</tr>
<tr>
<td>‘single_stripe’</td>
<td>Single stripe images, Gray code images and phase shift images</td>
</tr>
</tbody>
</table>

Usually, ‘gray_code_and_phase_shift’ leads to more accurate results than ‘gray_code’ because the combination between Gray code and phase images yields sub-pixel precise monitor coordinates. ‘single_stripe’ can increase robustness in case of only partially specular surfaces.

If ‘pattern_type’ is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: ‘gray_code_and_phase_shift’, ‘gray_code’, ‘single_stripe’
Default: ‘gray_code_and_phase_shift’

‘single_stripe_width’: Sets the width (in pixels) of the single stripe that is generated while calling gen_structured_light_pattern using the ‘pattern_type’ ‘single_stripe’.

The value has to be a power of two and has to be greater or equal ‘min_stripe_width’. Furthermore, it has to be smaller or equal the minimum of the parameters ‘pattern_width’ and ‘pattern_height’ after rounding both up to their next power of two.

Note that ‘single_stripe_width’ can only be set in case that ‘pattern_type’ is ‘single_stripe’. When ‘pattern_type’ is changed to ‘single_stripe’, ‘single_stripe_width’ is set to some power of two roughly halfway between the currently set ‘min_stripe_width’ and the minimum of ‘pattern_width’ and ‘pattern_height’.

If ‘single_stripe_width’ is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 4 and a power of 2
Default: power of two roughly halfway between the currently set ‘min_stripe_width’ and ‘pattern_width’, ‘pattern_height’

Parameters which influence the segmentation of the pattern region:

‘min_gray_difference’: Sets the minimum gray value difference for the Gray code images. This value is used within decode_structured_light_pattern to determine the binarized images. Thereby, for each pixel of the camera images the gray value difference between the lighted and the unlighted case is calculated. If the gray value difference of a pixel is smaller than ‘min_gray_difference’, it is excluded from the domain of the binarized images (see get_structured_light_object) and thus also from further calculations.

If ‘min_gray_difference’ is set to the value 0, the segmented region is identical to the input region of the camera images with the only exception that pixels with a decoding result outside the pattern images are excluded.

Values: integer values larger or equal to 0
Default: 30

Parameters which influence the defect image:

‘derivative_sigma’: Sets the sigma of the Gaussian (i.e. the amount of smoothing) that is used for the convolution of the correspondence image(s) to calculate the defect image.

Values: float or integer value larger or equal 0.01
Default: 2
CHAPTER 16 INSPECTION

Parameters

- **StructuredLightModel** (input_control)  
  Handle of the structured light model.

- **GenParamName** (input_control)  
  Name of the model parameter to be adjusted.
  
  Default value: 'min_stripe_width'
  
  List of values: GenParamName ∈ ['derivative_sigma', 'min_gray_difference', 'min_stripe_width', 'normalization', 'pattern_height', 'pattern_orientation', 'pattern_type', 'pattern_width', 'single_stripe_width', 'persistence']

- **GenParamValue** (input_control)  
  New value of the model parameter.
  
  Default value: 32
  
  Suggested values: GenParamValue ∈ {0, 0.01, 0.5, 0.7, 1, 1.4, 5, 50.0, 64, 128, 256, 1024, 'true', 'false', 'both', 'vertical', 'horizontal', 'global', 'inverted_pattern', 'gray_code_and_phase_shift', 'gray_code', 'single_stripe'}

Example

* Create the model
  `create_structured_light_model ('deflectometry', StructuredLightModel)`
* Set the size of the monitor
  `set_structured_light_model_param (StructuredLightModel, 'pattern_width', 1600)`
  `set_structured_light_model_param (StructuredLightModel, 'pattern_height', 1200)`
* Set the smallest width of the stripes in the pattern
  `set_structured_light_model_param (StructuredLightModel, 'min_stripe_width', 8)`
* Generate the patterns to project
  `gen_structured_light_pattern (PatternImages, StructuredLightModel)`
* Set the expected black/white contrast in the region of interest
  `set_structured_light_model_param (StructuredLightModel, 'min_gray_difference', 70)`
* Decode the camera images
  `decode_structured_light_pattern (CameraImages, StructuredLightModel)`
* Get the computed correspondences and defects
  `get_structured_light_object (CorrespondenceImages, StructuredLightModel, 'correspondence_image')`
  `get_structured_light_object (DefectImage, StructuredLightModel, 'defect_image')`

Result

The operator `set_structured_light_model_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **StructuredLightModel**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

write_structured_light_model ( : : StructuredLightModel,
FileName :

)

Write a structured light model to a file.
write_structured_light_model writes the structured light model StructuredLightModel to the
file given by FileName. The default HALCON file extension for the structured light model is ’hslm’. The
structured light model can be then read with read_structured_light_model. It should be noted that
write_structured_light_model does not write any previously generated pattern images in the structured light model. In other words, only the parameters of the model and objects that were already generated will be written in the file. The list of structured light objects and how to generate each can be found in
get_structured_light_object.
For an explanation of the concept of structured light and its supported applications, see the introduction of chapter
Inspection / Structured Light.
Parameters
. StructuredLightModel (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . structured_light_model ; handle
Handle of the structured light model.
. FileName (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . filename.write ; string
File name.
File extension: .hslm
Example
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Write the model
write_structured_light_model (StructuredLightModel, 'ExampleModel.hslm')
Result
The operator write_structured_light_model returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.
Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

16.4 Texture Inspection

This chapter describes the operators for texture inspection.

Concept of the texture inspection model

The texture inspection model enables the inspection of textured surfaces with only having to set few parameters. The algorithm requires images of flawless texture for training. The training process extracts texture features from the training images and trains a texture inspection model that is based on Gaussian Mixture Model (GMM) classifiers. After a successful training, texture images can be compared to the texture inspection model and potential defects can be identified. Texture inspection works on image pyramids. This way, multiple frequency ranges of the texture are analyzed.

It is possible to use multi-channel images in the texture inspection pipeline.

In the following, the steps that are required to perform the texture inspection are described briefly.

Create a texture inspection model: In a first step, a texture inspection model is created with

* create_texture_inspection_model

or read with

* read_texture_inspection_model.

Add training samples: The operator

* add_texture_inspection_model_image

adds sample images to the texture inspection model.

Images that have been added to the texture inspection model with the help of add_texture_inspection_model_image can be viewed with get_texture_inspection_model_image. If all or a part of the added images are not needed for the current texture inspection, they can be removed from the model using remove_texture_inspection_model_image.

Train a texture inspection model: The texture inspection model is trained with

* train_texture_inspection_model.

In the training process an image pyramid is created. For each pyramid level a Gaussian Mixture Model (GMM) is trained and a 'novelty_threshold' is determined. The 'novelty_threshold' helps to distinguish between flawless and defective texture. After the training, it is possible to query the novelty thresholds with get_texture_inspection_model_param.

Several parameters influence the training. They can be set with
16.4. TEXTURE INSPECTION

We recommend the following proceeding for the training:

- Set initial parameters for the training, if needed:
  - `'patch_normalization'`: Setting this parameter to `'weber'`, the features of the used texture patches are normalized making the texture inspection model more robust against illumination changes. Note, however, that sometimes a normalization might not be desired, e.g., if the brightness is needed to discriminate between flawless and defective parts. In that case, a controlled illumination is absolutely necessary for a successful classification.
  - `'patch_rotational_robustness'`: Setting this parameter to `'true'`, the features of the used texture patches are sorted in a way that is robust against rotational changes. This can be used if it is difficult to train all possible orientations of the textured surface via training samples.

- Train the texture inspection model (using the default parameters): The initial training of the texture inspection model may be very time consuming, depending on the number of training images and their resolution. The following time saving strategies can be considered:
  - Zoom the images: Often, the texture inspection works even better on low resolution images. If it is known that the full resolution of the images is not needed, you can significantly reduce the training time by zooming the images. Zooming the image down by a factor of 2, e.g., reduces the training time by factor 4.
  - Accelerate the training: Another, but more risky strategy is to increase the threshold for the stopping criterion of the classifier optimization by setting the parameter `'gmm_em_threshold'`, e.g., from 0.001 to 0.1. This leads to shorter training times but also to a possibly less accurate texture inspection model. If this strategy is used, we strongly recommend to reduce `'gmm_em_threshold'` again after most of the parameters have been adjusted.

- Check the result of the training: Use a set of images with defective textures, classify them with the trained texture inspection model and check the results as is described for the step 'Apply the texture inspection model'. If the results are not satisfying, further parameters can be adjusted for the training. The most important parameters are:
  - `'num_levels'` or `'levels'`: The number of used pyramid levels or the explicitly used pyramid levels. Higher pyramid levels work on coarser texture features. If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then runtime can be reduced by setting the pyramid levels of interest explicitly with `'levels'`. If for example the `'levels'` are set to [1,3], the training and the texture classification are only performed on the first and third level.
  - `'sensitivity'`: Controls how strict the novelty thresholds are set. This way, the sensitivity to novelties can be adjusted. In general, positive values lead to fewer detected defects and negative values lead to less detected defects.
  - `'novelty_threshold'`: Sets the novelty threshold manually. This can be used for fine tuning if the results of the automatic estimation are not optimal.

- Repeat the training, if needed: If parameters were adjusted, usually the texture inspection model has to be retrained.

**Apply the texture inspection model:** After successfully training the texture inspection model it can be used to classify textured surfaces. Each test image can be compared to the texture inspection model with

- `apply_texture_inspection_model`
For each test image the operator returns a 'novelty_region', which indicates where the image has high deviations to the trained texture samples. The 'novelty_region' is generated by combining the novelty regions of the different pyramid levels. The novelty regions of adjacent levels in the image pyramid are intersected with each other. This step helps to improve the robustness towards noise within the single pyramid level responses. The intersected novelty regions are then added to the returned 'novelty_region'. If a pyramid level has no adjacent pyramid level, the region itself is added to the 'novelty_region'. If, for example, 'num_levels' is set to 1, no adjacent pyramid level exists and the 'novelty_region' is the novelty region of the first pyramid level.

For debugging, the parameter 'gen_result_handle' can be set to 'true' with set_texture_inspection_model_param. This way, the novelty score images and novelty regions of the individual pyramid levels are stored in a result handle. They can then be read with

* get_texture_inspection_result_object.

In general, the novelty score images describe how well each pixel fits to the texture inspection model that was created within the training process. The novelty regions of the single pyramid levels are then calculated by applying the 'novelty_threshold' to the corresponding novelty score images.

Inspecting the novelty score images and the novelty regions provides you with hints which kinds of errors are detectable on which pyramid levels. Thus, you can decide whether parameters for the training and the classification should be adjusted, e.g., whether it is reasonable to explicitly select only a subset of pyramid levels using the parameter 'levels'.

The resulting 'novelty_score_image' (1) and the resulting 'novelty_region' (2) for the test image above.
Further operators

The functionality of the texture inspection can be altered by various parameters. The parameters can be queried with `get_texture_inspection_model_param` and altered with calls to `set_texture_inspection_model_param`.

It is possible to write a texture inspection model to file with the operator `write_texture_inspection_model`. Thereby, only the texture inspection model is stored. The images which were possibly added can be queried with the help of `get_texture_inspection_model_image` and stored separately by calling `write_object`.

To help reduce the memory required by the texture inspection model, it is possible to delete previously added images from the model with `remove_texture_inspection_model_image`.

Furthermore, it is possible to serialize and deserialize the texture inspection model with `serialize_texture_inspection_model` and `deserialize_texture_inspection_model`.

Glossary

In the following, the most important terms that are used in the context of texture inspection are described:

**Training images** Images that are used for training.

**Test images** Images which are compared to the trained texture inspection model.

**Patch** A collection of neighboring pixels.

**Texture feature** The pixel values within a patch.

**Sample** A texture feature that is used for training.

**Novelty Score** In the test process the texture features of the test images are compared to the texture inspection model and their 'novelty score' is calculated. The larger this value, the more probable it is that the individual texture feature does not fit to the texture inspection model.

**Novelty Threshold** The novelty threshold is determined during the training process. Texture features with a novelty score below the novelty threshold fit to the texture inspection model. Texture features with a higher novelty score do not.

```
add_texture_inspection_model_image (Image : TextureInspectionModel : Indices)
```

Add training images to the texture inspection model.

`add_texture_inspection_model_image` adds training images to the texture inspection model (`TextureInspectionModel`). The domain of the training images is considered in all further calculations. Since the feature extraction considers a certain neighborhood of each pixel, no features can be extracted for pixels at the border of the domain. The border size (`Border`) depends on the 'patch_size' and computes to

\[
\text{Border} = \frac{\text{patch\_size}}{2} - 1.
\]

All images which are added to the texture inspection model are used within the training process (see `train_texture_inspection_model` for more information). Furthermore, it is possible to query all of the images passed to the texture inspection model with `get_texture_inspection_model_image`.

Every added image receives an index (`Indices`), which allows the user to generate an assignment between the added images and his image data. By calls of `remove_texture_inspection_model_image`, the index can further be used to delete images from the model that are not needed anymore.

It is possible to add either gray-scale images or multichannel images. However, all of the passed images should have the same number of channels.

For an explanation of the concept of the texture inspection see the introduction of chapter `Inspection / Texture Inspection`. 
Parameters

- **Image** (input_object) ..................... (multichannel-image-array) \(\sim\) object : byte / uint2 / real
  Image of flawless texture.
- **TextureInspectionModel** (input_control) .................. texture_inspection_model \(\sim\) handle
  Handle of the texture inspection model.
- **Indices** (output_control) .................................................. integer-array \(\sim\) integer
  Indices of the images that have been added to the texture inspection model.

Example

* Create texture inspection model
  ```
  create_texture_inspection_model ('basic', TextureInspectionModel)
  ```
* Make this short example fast:
  ```
  set_texture_inspection_model_param (TextureInspectionModel, \n    'gmm_em_max_iter', 1)
  ```
* Read and add training images
  ```
  read_image (TrainImage, 'carpet/carpet_01')
  add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \n    Indices)
  ```
* Train the model
  ```
  train_texture_inspection_model (TextureInspectionModel)
  ```
* Read and apply a test image
  ```
  read_image (TrainImage, 'carpet/carpet_02')
  apply_texture_inspection_model (TestImage, DefectCandidates, \n    TextureInspectionModel, \n    TextureInspectionResultID)
  ```

Result

The operator `add_texture_inspection_model_image` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- create_texture_inspection_model,
- set_texture_inspection_model_param,
- get_texture_inspection_model_param

Possible Successors

- train_texture_inspection_model,
- clear_texture_inspection_model,
- remove_texture_inspection_model_image,
- get_texture_inspection_model_image

Matching

**apply_texture_inspection_model** ( Image : NoveltyRegion : 
  TextureInspectionModel : TextureInspectionResultID )

Inspection of the texture within an image.
The operator `apply_texture_inspection_model` compares `Image` with the trained texture inspection model `TextureInspectionModel`. `Image` can either be a single image or a tuple of images. It is possible to pass either gray-scale or multichannel images. Hereby, the operator expects that the passed `Image` has the same number of channels than the model was trained with. The runtime of the `apply_texture_inspection_model` scales roughly linearly with the number of image channels. However, models using colored images are generally better at detecting colored texture defects.

Pixels that do not fit to the texture inspection model are returned in `NoveltyRegion`. Furthermore, if `gen_result_handle` has been set to 'true' with `set_texture_inspection_model_param`, the operator also returns the result handle `TextureInspectionResultID` with more detailed information on the texture classification. If `gen_result_handle` is set to 'false', `TextureInspectionResultID` is empty.

For an explanation of the concept of the texture inspection see the introduction of chapter `Inspection / Texture Inspection`.

For each pyramid level texture features are extracted and classified with the corresponding GMM classifier. The resulting novelty score is then compared to the novelty threshold of the current pyramid level and classified as defective or not. The defective pixels are collected in a novelty region for each pyramid level. These novelty regions are then combined to the final novelty region returned in `NoveltyRegion`. The novelty regions of adjacent levels in the image pyramid are intersected with each other. This step helps to improve the robustness towards noise within the single pyramid level responses. The intersected novelty regions are then added to the returned `novelty_region`. If a pyramid level has no adjacent pyramid level the region itself is added to the `novelty_region`. If, for example, `num_levels` is set to 1, no adjacent pyramid level exists and the `novelty_region` is the novelty region of the first pyramid level.

If `gen_result_handle` is set to 'true', the result handle `TextureInspectionResultID` contains novelty score images and the resulting novelty regions for each pyramid level.

This information is useful for debugging and fine tuning of the model parameters (e.g., the novelty thresholds) and can be accessed with `get_texture_inspection_result_object`.

--- Parameters ---

- **Image** (input_object) {multichannel-image-array} ~ object: byte / uint2 / real
  Image of the texture to be inspected.
- **NoveltyRegion** (output_object) {region-array} ~ object
  Novelty regions.
- **TextureInspectionModel** (input_control) {texture_inspection_model} ~ handle
  Handle of the texture inspection model.
- **TextureInspectionResultID** (output_control) {texture_inspection_result} ~ handle
  Handle of the inspection results.

--- Example ---

* Create texture inspection model  
  create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters  
  set_texture_inspection_model_param (TextureInspectionModel, 'gen_result_handle', 'true')
* Make this short example fast:  
  set_texture_inspection_model_param (TextureInspectionModel, 'gmm_em_max_iter', 1)
* Read and add training images  
  read_image (TrainImage, 'carpet/carpet_01')
  add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)
* Train the model  
  train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image  
  read_image (TestImage, 'carpet/carpet_02')
  apply_texture_inspection_model (TestImage, DefectCandidates, TextureInspectionModel, TextureInspectionResultID)
The operator `apply_texture_inspection_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- `TextureInspectionResultID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

- `train_texture_inspection_model`

**Possible Successors**

- `get_texture_inspection_result_object`, `get_texture_inspection_model_param`, `clear_texture_inspection_result`, `clear_texture_inspection_model`

**Module**

```
clear_texture_inspection_model { : : TextureInspectionModel : } ...
```

Clear a texture inspection model and free the allocated memory.

The operator `clear_texture_inspection_model` deletes a texture inspection model that was created by `create_texture_inspection_model`. All memory used by the model is freed. The handle of the model is passed in `TextureInspectionModel`. It is invalid after the operator call.

For an explanation of the concept of the texture inspection see the introduction of chapter *Inspection / Texture Inspection*.

**Parameters**

- `TextureInspectionModel` (input_control)  ...
  `texture_inspection_model(-array) ~ handle`

  Handle of the texture inspection model.

**Example**

* Create texture inspection model
  `create_texture_inspection_model ('basic', TextureInspectionModel)`
* Read and add training images
  `read_image (TrainImage, 'carpet/carpet_01')`
  `add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)`
* Train the model
  `train_texture_inspection_model (TextureInspectionModel)`
* Read and apply a test image
  `read_image (TestImage, 'carpet/carpet_02')`
  `apply_texture_inspection_model (TestImage, DefectCandidates, TextureInspectionModel, TextureInspectionResultID)`
### 16.4. TEXTURE INSPECTION

---

The operator `clear_texture_inspection_model` returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred texture inspection model can be freed correctly. Otherwise, an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TextureInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

See also `create_texture_inspection_model`

---

### Module

Matching

---

#### `clear_texture_inspection_result`

```markdown
(input_control) . . . . . . . . . . . texture_inspection_result(-array) ;
```

Clear a texture inspection result handle and free the allocated memory.

The operator `clear_texture_inspection_result` clears the texture inspection result `TextureInspectionResultID` that was created by `apply_texture_inspection_model`. All memory used by the model is freed. The handle of the model is invalid after the operator call.

For an explanation of the concept of the texture inspection see the introduction of chapter `Inspection / Texture Inspection`.

---

**Parameters**

- `TextureInspectionResultID` (input_control) ........... texture_inspection_result(-array) ➞ `handle`
  Handle of the texture inspection results.

---

**Example**

* Create texture inspection model
  ```
  create_texture_inspection_model ('basic', TextureInspectionModel)
  *
  * Make this short example fast:
    ```
    set_texture_inspection_model_param (TextureInspectionModel, \ 
      'gmm_em_max_iter', 1)
    *
    * Set parameter to generate a result handle
      ```
      set_texture_inspection_model_param (TextureInspectionModel, \ 
        'gen_result_handle', 'true')
      *
    * Read and add training images
      ```
      read_image (TrainImage, 'carpet/carpet_01')
      add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \ Indices)
      *
    * Train the model
      ```
      train_texture_inspection_model (TextureInspectionModel)
      *
    * Read and apply a test image
      ```
      read_image (TestImage, 'carpet/carpet_02')
      apply_texture_inspection_model (TestImage, DefectCandidates, \ TextureInspectionModel, \ TextureInspectionResultID)
      ```
    ```
The operator `clear_texture_inspection_result` returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred texture inspection model can be freed correctly. Otherwise, an exception will be raised.

Parallellization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TextureInspectionResultID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `apply_texture_inspection_model`

### Module

#### `create_texture_inspection_model`

Create a texture inspection model.

`create_texture_inspection_model` creates a new texture inspection model of type `ModelType`. Currently, only the model type `'basic'` is supported.

The parameters of the texture inspection can be queried with `get_texture_inspection_model_param` and manipulated by calls to `set_texture_inspection_model_param`.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

### Parameters

- `ModelType` (input_control) : string
  The type of the created texture inspection model.
- `TextureInspectionModel` (output_control) : texture_inspection_model
  Handle for using and accessing the texture inspection model.

### Example

* Create texture inspection model
`create_texture_inspection_model ('basic', TextureInspectionModel)`
* Make this short example fast:
`set_texture_inspection_model_param (TextureInspectionModel, \gmm_em_max_iter', 1)`
* Read and add training images
`read_image (TrainImage, 'carpet/carpet_01')`
`add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)`
* Train the model
`train_texture_inspection_model (TextureInspectionModel)`
* Read and apply a test image
`read_image (TestImage, 'carpet/carpet_02')`
`apply_texture_inspection_model (TestImage, DefectCandidates, TextureInspectionModel, TextureInspectionResultID)`
16.4. TEXTURE INSPECTION

Result

The operator create_texture_inspection_model returns the value 2 (H_MSG_TRUE) in the texture inspection model can be allocated correctly. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_texture_inspection_model_param, get_texture_inspection_model_param, add_texture_inspection_model_image

Module

deserialize_texture_inspection_model ( : :SerializedItemHandle : TextureInspectionModel )

Deserialize a serialized texture inspection model.

deserialize_texture_inspection_model deserializes a texture inspection model, that was serialized by serialize_texture_inspection_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized texture inspection model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created texture inspection model with the handle TextureInspectionModel.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters

- SerializedItemHandle (input_control) ......................... serialized_item ~ handle
Handle of the serialized item.
- TextureInspectionModel (output_control) ..................... texture_inspection_model ~ handle
Handle of the texture inspection model.

Example

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \ 'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \ 'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \ Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Serialize texture inspection model
serialize_texture_inspection_model (TextureInspectionModel, \ SerializedItemHandle)
* Deserialize in Model

deserialize_texture_inspection_model (SerializedItemHandle, \
    TextureInspectionModelSerialized)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
    TextureInspectionModelSerialized, \
    TextureInspectionResultID)

If the parameters are valid, the operator deserialize_texture_inspection_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

fread_serialized_item, receive_serialized_item, 
serialize_texture_inspection_model

**Possible Successors**

apply_texture_inspection_model

**See also**

create_texture_inspection_model, write_texture_inspection_model, 
serialize_texture_inspection_model

**Module**

Matching

---

get_texture_inspection_model_image ( 
    : ModelImages : TextureInspectionModel : )

Get the training images contained in a texture inspection model.

The operator get_texture_inspection_model_image returns all training images contained in a texture inspection model TextureInspectionModel that were added by add_texture_inspection_model_image.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

**Parameters**

- **ModelImages** (output_object) .........................(multichannel-)image-array  ~ object : byte / uint2 
  Training images contained in the texture inspection model.
- **TextureInspectionModel** (input_control) ..................texture_inspection_model  ~ handle 
  Handle of the texture inspection model.

**Example**

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, 'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (ModelImages, TextureInspectionModel, Indices)

* Get added training images
get_texture_inspection_model_image (ModelImagesOut, TextureInspectionModel)

---

**Result**

The operator `get_texture_inspection_model_image` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

---

**Possible Predecessors**

create_texture_inspection_model, set_texture_inspection_model_param,
get_texture_inspection_model_param, add_texture_inspection_model_image

**Possible Successors**

train_texture_inspection_model, clear_texture_inspection_model,
remove_texture_inspection_model_image

---

**Module**

Matching

---

`get_texture_inspection_model_param` ( : : TextureInspectionModel,
GenParamName : GenParamValue )

Query parameters of a texture inspection model.

The operator `get_texture_inspection_model_param` is used to query the values of the different parameters of a texture inspection model (TextureInspectionModel). The names of the desired parameters are passed in the parameter GenParamName, the corresponding values are returned in GenParamValue. It is possible to query multiple parameters with a single call to `get_texture_inspection_model_param`. All parameters which can be manipulated by `set_texture_inspection_model_param` can be queried. Please refer to the documentation of `set_texture_inspection_model_param` for an explanation of the individual parameters. It is furthermore possible to query the following parameters:

'gmm_centers': Returns the number of Gaussian distributions which were determined as optimal within the training process. The value can be used as a reference for future texture inspection models. The range of the possible number of distributions is determined by the settings of the parameters 'gmm_pmincenters' and 'gmm_pmaxcenters'. Each image pyramid level can have a different number of Gaussian distributions. By adding an index, the number of Gaussian distributions for specific pyramid levels can be queried. For example, 'gmm_centers_3' returns the number of Gaussian distributions for the third pyramid level.

'image_indices': Returns the indices of the images that have been added to the texture inspection model using `add_texture_inspection_model_image`. Only indices of images are returned that are currently in the texture inspection model and have not been deleted with `remove_texture_inspection_model_image`.

'trained_covartype': Returns the type of covariance matrix that was used during training. The user has the possibility to set the preferred type of covariance matrix by setting 'gmm_covartype' with `set_texture_inspection_model_param`. However, if the training with the preferred covariance type fails, training is re-initialized with a less strict 'gmm_covartype'. Hence, if training with 'diag' fails, a further training with 'spherical' is attempted.

---

HALCON 20.05.0.0
In order to avoid confusions regarding the returned tuple length, multivalued parameters, such as 'image_indices', 'gmm_centers', 'levels' and 'novelty_threshold' can only be queried alone i.e. without passing any other parameter to get_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

**Parameters**

- **TextureInspectionModel** (input_control) texture_inspection_model handle
  Handle of the texture inspection model.

- **GenParamName** (input_control) GenParamName string(-array)
  Name of the queried model parameter.
  **Default value:** 'novelty_threshold'
  **List of values:** GenParamName ∈ {'num_levels', 'levels', 'gen_result_handle', 'novelty_threshold', 'sensitivity', 'patch_normalization', 'patch_rotational_robustness', 'patch_size', 'gmm_centers', 'gmm_sigma', 'gmm_pmincenters', 'gmm_pmaxcenters', 'gmm_preprocessing', 'gmm_ncomp', 'gmm_randseed', 'gmm_em_max_iter', 'gmm_em_threshold', 'gmm_em_regularize', 'gmm_covartype', 'image_indices', 'trained_covartype'}

- **GenParamValue** (output_control) GenParamValue string(-array)
  Value of the queried model parameter.

**Example**

* Create texture inspection model
  ```
  create_texture_inspection_model ('basic', TextureInspectionModel)
  *
  * Make this short example fast:
    ```
    set_texture_inspection_model_param (TextureInspectionModel, 
        'gmm_em_max_iter', 1)
    *
    * Get parameters
      ```
      get_texture_inspection_model_param (TextureInspectionModel, 'patch_size', 
          PatchSize)
      *
      * Read and add training images
        ```
        read_image (TrainImage, 'carpet/carpet_01')
        add_texture_inspection_model_image (TrainImage, TextureInspectionModel, 
            Indices)
        *
      * Train the model
        ```
        train_texture_inspection_model (TextureInspectionModel)
        *
      * Read and apply a test image
        ```
        read_image (TestImage, 'carpet/carpet_02')
        apply_texture_inspection_model (TestImage, DefectCandidates, 
            TextureInspectionModel, 
            TextureInspectionResultID)
        *
      **Result**
      The operator get_texture_inspection_model_param returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- create_texture_inspection_model, train_texture_inspection_model

**Possible Successors**

- add_texture_inspection_model_image, train_texture_inspection_model

**See also**

set_texture_inspection_model_param

Module

get_texture_inspection_result_object (  
  : Object : TextureInspectionResultID,  
  : ResultName : )

Query iconic results of a texture inspection.

get_texture_inspection_result_object queries the iconic result ResultName of the handle TextureInspectionResultID returned by apply_texture_inspection_model. The result handle TextureInspectionResultID was only created when 'gen_result_handle' was set to 'true' with set_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

In the following the possible parameter values for ResultName are listed:

'novelty_region': Returns the novelty regions of all pyramid levels in an object tuple. To query the novelty regions of single pyramid levels the corresponding index has to be added, e.g., 'novelty_region_1'. Please note that if a tuple of images was passed to apply_texture_inspection_model, it is only possible to query the novelty regions for the first image within the tuple.

'novelty_score_image': Returns the novelty score images of all pyramid levels in an object tuple. To query the novelty regions of single pyramid levels the corresponding index has to be added, e.g., 'novelty_score_image_1'. Please note that if a tuple of images was passed to apply_texture_inspection_model, it is only possible to query the novelty score images for the first image within the tuple.

Parameters

Object (output_object) object(-array) ~ object  
Returned iconic object.

TextureInspectionResultID (input_control) texture_inspection_result handle  
Handle of the texture inspection result.

ResultName (input_control) string(-array) ~ string / integer  
Name of the iconic object to be returned.

Default value: 'novelty_region'

List of values: ResultName ∈ {'novelty_score_image', 'novelty_region'}

Example

* Create texture inspection model  
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters  
set_texture_inspection_model_param (TextureInspectionModel, \  
  'gen_result_handle', 'true')
  * Make this short example fast:  
set_texture_inspection_model_param (TextureInspectionModel, \  
  'gmm_em_max_iter', 1)
  * Read and add training images  
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \  
  Indices)
  * Train the model  
train_texture_inspection_model (TextureInspectionModel)
  * Read and apply a test image  
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \  
  TextureInspectionModel, \  
  TextureInspectionResultID)

HALCON 20.05.0.0
* Get result objects

get_texture_inspection_result_object (Object, TextureInspectionResultID, 'novelty_score_image')

--- Result ---

The operator get_texture_inspection_result_object returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Possible Predecessors ---

apply_texture_inspection_model

--- Possible Successors ---

clear_texture_inspection_result, clear_texture_inspection_model

--- Module ---

Matching

```
read_texture_inspection_model ( FileName : TextureInspectionModel )
```

Read a texture inspection model from a file.

read_texture_inspection_model reads a texture inspection model that has been stored with write_texture_inspection_model. Since the training of a texture inspection model can consume a relatively long time, the texture inspection model is typically trained in an offline process and written to a file with write_texture_inspection_model. In the online process the texture inspection model is read with read_texture_inspection_model and subsequently used for evaluation with apply_texture_inspection_model. The default HALCON file extension for the texture inspection model is '.htim'.

After reading a trained texture inspection model, it is possible to classify test images using apply_texture_inspection_model. However, retraining this model can only be done, if the read model has images. Furthermore, modifying parameters of the model leads to an entire retraining.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

--- Parameters ---

- **FileName** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . filename.read  ~ string
  File name.
  File extension: .htim
- **TextureInspectionModel** (output_control) . . . . . . . . . . . . . . . . . . . texture_inspection_model  ~ handle
  Handle of the texture inspection model.

--- Example ---

* Create texture inspection model

create_texture_inspection_model ('basic', TextureInspectionModel)

* Make this short example fast:

set_texture_inspection_model_param (TextureInspectionModel, 'gmm_em_max_iter', 1)

* Read and add training images

read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
**16.4. TEXTURE INSPECTION**

* Train the model
  `train_texture_inspection_model (TextureInspectionModel)`

* Write out texture inspection model
  `write_texture_inspection_model (TextureInspectionModel, 'ExampleModel.hitim')`

* Read in Model
  `read_texture_inspection_model ('ExampleModel.hitim', TextureInspectionModelRead)`

* Read and apply a test image
  `read_image (TestImage, 'carpet/carpet_02')`
  `apply_texture_inspection_model (TestImage, DefectCandidates, TextureInspectionModelRead, TextureInspectionResultID)`

**Result**

If the parameters are valid, the operator `read_texture_inspection_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Predecessors**

- `write_texture_inspection_model`

**Possible Successors**

- `apply_texture_inspection_model`

**See also**

**Module**

---

```plaintext
remove_texture_inspection_model_image ( 
  : : TextureInspectionModel, Indices : RemainingIndices )
```

Clear all or a user-defined subset of the images of a texture inspection model.

The function `remove_texture_inspection_model_image` clears all or certain selected images that have been stored in a texture inspection model `TextureInspectionModel`.

On the other hand, the usage of `remove_texture_inspection_model_image` is recommended to reduce the storage space of a saved texture inspection model. This is especially of advantage if the texture inspection model has been trained in an offline process and written with `write_texture_inspection_model`. In this case, test images can still be classified using `apply_texture_inspection_model`, while the required storage space is reduced to a minimum. On the other hand, it offers a simple way to delete certain selected images of the texture inspection model that are not needed (anymore) for a subsequent classification process. This allows the user to proceed with an entirely configured model, while only the used image data has to be tuned to solve the underlying inspection problem. Please note that after removing images from the model a retraining is required.

In order to specifically delete images from the texture inspection model, the indices of the respective images have to be specified in the parameter `Indices`. A validation of all images that are still in the texture inspection model can be made using the value `image_indices` in `get_texture_inspection_model_param`. If the user...
still passes unassigned indices to delete images, these indices are ignored. Besides the above mentioned option, remove_texture_inspection_model_image also allows to set the parameter Indices to the value 'all'. In this case, all images of the texture inspection model are deleted.

It should be noted that after deleting all images, the model can only be (re)trained, if new images are added using add_texture_inspection_model_image. In the case that only a subset of all images has been deleted, a call of train_texture_inspection_model requires all steps of the training to be executed, since potentially still available training data does not match the used data.

After calling remove_texture_inspection_model_image, the remaining indices of the images that are still in the texture inspection model are returned in the parameter RemainingIndices.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

### Parameters

- **TextureInspectionModel** (input_control) texture_inspection_model(-array) handle
  - Handle of the texture inspection model.

- **Indices** (input_control) Indices of the images to be deleted from the texture inspection model.

- **RemainingIndices** (output_control) Indices of the images that remain in the texture inspection model.

### Example

```c
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)
* Get added training images
get_texture_inspection_model_image (TrainImageOut, TextureInspectionModel)
* Remove training images
remove_texture_inspection_model_image (TextureInspectionModel, Indices, RemainingIndices)
```

### Result

If the parameters are valid, the operator remove_texture_inspection_model_image returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- train_texture_inspection_model

add_texture_inspection_model_image

### Module

serialize_texture_inspection_model ( : : TextureInspectionModel : SerializedItemHandle )

Serialize a texture inspection model.

serialize_texture_inspection_model serializes a texture inspection model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The texture inspection model is defined by the handle TextureInspectionModel. The serialized texture inspection model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_texture_inspection_model.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters

▷ TextureInspectionModel (input_control) ................. texture_inspection_model ~ handle
   Handle of the texture inspection model.
▷ SerializedItemHandle (output_control) ......................... serialized_item ~ handle
   Handle of the serialized item.

Example

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \   'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \   'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \   Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Serialize texture inspection model
serialize_texture_inspection_model (TextureInspectionModel, \   SerializedItemHandle)
* Deserialize in Model
deserialize_texture_inspection_model (SerializedItemHandle, \   TextureInspectionModelSerialized)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \   TextureInspectionModelSerialized, \   TextureInspectionResultID)

Result

If the parameters are valid, the operator serialize_texture_inspection_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

set_texture_inspection_model_param ( : : TextureInspectionModel,
    GenParamName, GenParamValue : )

Set parameters of a texture inspection model.

The operator set_texture_inspection_model_param is used to manipulate the parameters of a texture inspection model TextureInspectionModel. The current parameter settings can be queried with the operator get_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

General parameters:

'num_levels': Determines the number of pyramid levels used within the texture inspection process. The number of pyramid levels affects the inspection results as well as the runtime of train_texture_inspection_model and apply_texture_inspection_model. Per default the number of levels is estimated by the size of the training images. It should be noted, that no more than 5 pyramid levels are used by the estimation process.

Changing this parameter can require a complete new training of the texture inspection model. No retraining is required if the number of levels of a trained texture inspection model are merely reduced.

If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then you can save a lot of runtime by setting the levels of interest explicitly with 'levels'.

Values: integer values larger or equal to 1 or 'auto'
Default: 'auto'

'levels': Determines the pyramid levels used within the texture inspection process. The number of pyramid levels affects the inspection results as well as the runtime of train_texture_inspection_model and apply_texture_inspection_model. Per default the pyramid levels are determined by the value of 'num_levels'. If for example 'num_levels' is set to four, then the texture inspection is performed for levels 1 to 4. If all available levels should be trained, the value has to be set to 'auto'.

Changing this parameter can require a complete new training of the texture inspection model. No retraining is required if the number of levels of a trained texture inspection model are merely reduced.

If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then you can save a lot of runtime by excluding unwanted levels by setting the pyramid levels with 'levels' explicitly.

In order to avoid confusions regarding the returned tuple length, 'levels' can only be set alone i.e. without passing any other parameter to set_texture_inspection_model_param.

Values: a monotonically increasing tuple of integer values larger or equal to 1, or 'auto'
Default: 'auto'

'gen_result_handle': This parameter determines whether or not a result handle is returned by apply_texture_inspection_model. If set to 'true', the individual pyramid level results can be queried from the texture result handle with get_texture_inspection_result_object. This is useful for debugging and fine tuning.

If set to 'false', apply_texture_inspection_model only returns a novelty region.

Values: 'true', 'false'
Default: 'false'

Parameters which influence the automatic novelty threshold calculation:
'novelty_threshold': This parameter sets the values of the novelty thresholds, which distinguish between defective and non-defective texture. The novelty thresholds are passed as a tuple and are set for all pyramid levels at once. Therefore, the number of elements must be equal to the number of pyramid levels 'num_levels'.

Setting the novelty thresholds prior to training has no effect since the training automatically determines novelty thresholds. Hence the novelty thresholds should be adapted after the training. A typical use case is the fine tuning to optimize the results of apply_texture_inspection_model. Please note, if the novelty thresholds have been set explicitly, a new call of train_texture_inspection_model will re-estimate the novelty thresholds automatically and overwrite any explicitly set novelty thresholds.

It is possible to add an index to set the novelty threshold of a specific pyramid level. For example, 'novelty_threshold_3' sets the novelty threshold for the third pyramid level.

Values: integer or float values larger or equal to 0 and smaller or equal to 710

Default: Is determined by train_texture_inspection_model

'sensitivity': This parameter influences the sensitivity of the novelty thresholds which are determined during the training with train_texture_inspection_model. Per default 'sensitivity' is set to 0.0, which means the novelty thresholds from the training are used directly when calling apply_texture_inspection_model. If a negative value for the parameter 'sensitivity' is used, the value is added to the novelty boundaries. Hence, a sensitivity value below 0.0 increments the novelty thresholds and therefore leads to potentially fewer detected errors. If instead a positive value is set, the novelty thresholds are decremented which leads to potentially more detected errors.

The automatically determined novelty thresholds can be changed after the training with the parameter 'novelty_threshold'.

Values: float or integer value

Default: 0.0

Parameters that influence the texture features:

'patch_normalization': Determines the method used to normalize the texture features. A normalization is required if the lighting between different images is not consistent. If set to 'weber', the patches are normalized in accordance with the Weber-Fechner law. If the parameter is set to 'none', no feature normalization is performed.

Changing this parameter requires a complete new training of the texture inspection model.

Values: 'none', 'weber'

Default: 'none'

'patch_rotational_robustness': If set to 'true', the texture features are sorted in a way to obtain a certain amount of rotational invariance. Sorting the features leads to a loss of feature information and generally makes the texture inspection less sensitive. Also, the runtime is slightly increased. If the parameter is set to 'false', the texture features are not sorted.

Alternatively, it is possible to capture all possible rotations within the training images. Increasing the training images leads to an increase of the training time.

Changing this parameter requires a complete new training of the texture inspection model.

Values: 'true', 'false'

Default: 'false'

'patch_size': This parameter determines the diameter of the extracted texture feature patches in pixels. Higher patch sizes increase the runtime significantly. Therefore this parameter should only be changed with great care. First try to change the image resolution or the number of pyramids used.

Changing this parameter requires a complete new training of the texture inspection model.

Values: odd integer values between 1 and 11

Default: 5

Advanced parameters that influence the GMM classifiers:

Internally, the texture inspection model uses a Gaussian Mixture Model (GMM) classifier. In general, it is recommended not to change the GMM parameters, but for experienced users this is still possible.

Changing these parameters requires a new training of the texture inspection model.

In the following, the parameters which influence the GMM classifiers are described. For more information on classification with GMM classifiers, see create_class_gmm and train_class_gmm.
'gmm_sigma': This parameter determines the standard deviation of the Gaussian noise which is added to the training samples (see `add_sample_class_gmm`).
Values: integer or float values larger or equal to 0.0
Default: 0.0

'gmm_pmincenters': This parameter determines the minimum number of Gaussian distributions per class. 'gmm_pmincenters' cannot be set to a value larger than the current value of 'gmm_pmaxcenters'.
Values: integer value larger or equal to 1 and less or equal to 'gmm_pmaxcenters'
Default: 12

'gmm_pmaxcenters': This parameter determines the maximum number of Gaussian distributions per class. 'gmm_pmaxcenters' cannot be set to a value smaller than the current value of 'gmm_pmincenters'.
Values: integer value larger or equal to 'gmm_pmincenters'
Default: 12

'gmm_preprocessing': This parameter determines the type of preprocessing used to transform the feature vectors.
Values: 'principal_components', 'normalization', 'none'
Default: 'normalization'

'gmm_ncomp': This parameter manipulates the preprocessing in case 'principal_components' is chosen as the preprocessing method. More specifically, it determines the dimension of the transformed feature vectors. It needs to be chosen such that it is smaller than the feature dimension, which is $\text{PatchSize} \times \text{PatchSize}$. If the PatchSize is changed such that $\text{PatchSize} \times \text{PatchSize} < \text{gmm_ncomp}$, the parameter is manipulated accordingly.
Values: integer value larger or equal to 1
Default: 15

'gmm_randseed': This parameter determines the initialization value for the random number generator, which is required to initialize the GMM with random values.
Values: integer value
Default: 42

'gmm_em_max_iter': This parameter determines the maximum number of iterations of the expectation maximization algorithm.
Values: integer values larger or equal to 0
Default: 100

'gmm_em_threshold': This parameter determines the threshold for the relative change of the error for the expectation maximization algorithm to terminate.
Values: integer or float value larger or equal to 0 and smaller than 1.0
Default: 0.001

'gmm_em_regularize': This parameter determines the regularization value for preventing covariance matrix singularity within the training process.
Values: integer or float values larger or equal to 0 and smaller than 1.0
Default: 0.0001

'gmm_covartype': This parameter determines the type of covariance matrix that is used internally.
Values: 'spherical', 'diag', 'full'
Default: 'diag'

Changing the parameters of a trained texture inspection model
If parameters of a texture inspection model are manipulated after a successful call of `train_texture_inspection_model`, the texture inspection model usually needs to be retrained. Depending on which parameters are changed, different parts of the training need to be recalculated.

A manipulation of the parameters 'gmm_*' requires a new training of the classifiers. Since a new classifier yields different novelty scores, the novelty thresholds also need to be recalculated. The parameter 'patch_*' requires a complete new training of the texture inspection model. The parameters 'num_levels' and 'levels' require a retraining if the number of levels is increased or levels are set which were not trained beforehand. For example, setting 'levels' from [1,2,3] to [1,3] does not require a retraining. The operator 'gen_result_handle' has no effect on a trained texture inspection model and can be manipulated without requiring any retraining.
16.4. TEXTURE INSPECTION

Parameters

- **TextureInspectionModel** (input_control)  texture_inspection_model ⇒ handle
  Handle of the texture inspection model.
- **GenParamName** (input_control) attribute.name(-array) ⇒ string
  Name of the model parameter to be adjusted.
  **Default value:** 'gen_result_handle'
  **List of values:** GenParamName ∈ {'num_levels', 'levels', 'gen_result_handle', 'novelty_threshold', 'sensitivity', 'patch_normalization', 'patch_rotational_robustness', 'patch_size', 'gmm_sigma', 'gmm_pmincenters', 'gmm_pmaxcenters', 'gmm_preprocessing', 'gmm_ncomp', 'gmm_randseed', 'gmm_em_max_iter', 'gmm_em_threshold', 'gmm_em_regularize', 'gmm_covartype'}
- **GenParamValue** (input_control) attribute.value(-array) ⇒ integer / real / string
  New value of the model parameter.
  **Default value:** 'true'
  **List of values:** GenParamValue ∈ {5, 'auto', 'true', 'false', 'none', 'weber', 'principal_components', 'normalization'}

Example

```haskell
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \
  'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
  'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
  Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \n  TextureInspectionModel, \n  TextureInspectionResultID)
```

Result

The operator `set_texture_inspection_model_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **TextureInspectionModel**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

* create_texture_inspection_model

Possible Successors

* add_texture_inspection_model_image
  * train_texture_inspection_model
Train a texture inspection model.

train_texture_inspection_model trains a texture inspection model with all training images which were added by add_texture_inspection_model_image.

The complete texture inspection process works with image pyramids. The depth of the pyramid is determined by the parameter 'num_levels' (or 'levels' if the levels have been set explicitly). In the first step of the training, texture features are extracted and added to the set of training samples for each pyramid level. For each pyramid level a Gaussian Mixture Model (GMM) classifier is determined with all training samples of the corresponding pyramid level. In a third step, the training samples are used to determine a novelty threshold for each pyramid level. In the following, the three training steps are explained in detail:

1. **Feature extraction** extracts a feature for each pixel within the training images. The texture features are calculated according to the settings of the 'patch_*' parameters, which can be manipulated with set_texture_inspection_model_param. Each texture feature is added to the training data of the GMM.

2. **During the training** of the GMMs, the optimal 'gmm_*' parameters are calculated from the training data. The dimension of the single GMMs is determined by the size of the feature patches. Please refer to set_texture_inspection_model_param for details. For large patch sizes, it can be extremely difficult to obtain a good approximation of the optimal GMM parameters. Also, the run time and memory usage rises significantly. Therefore we recommend to alter the default patch size with care.

   More information on GMM classifiers can be found in the description of the operator create_class_gmm.

3. **The calculation of the novelty thresholds** is required to be able to distinguish between defective and non-defective texture. First, the novelty score of each training sample is determined with the GMMs determined in step 2. Then, based on the resulting novelty scores, novelty thresholds are determined for each pyramid level. The automatic determination of the novelty thresholds can be influenced with the parameter 'sensitivity' that can be set with set_texture_inspection_model_param.

After the training was successful it is possible to classify images with apply_texture_inspection_model. Each pixel is assigned a 'novelty score' that is compared to the novelty threshold, which was determined within the third step of the training. For optimal results it is possible to adapt the novelty threshold of the single pyramid levels with set_texture_inspection_model_param.

In general, the manipulation of all parameters, with the exception of 'gen_result_handle' and 'sensitivity', requires a retraining of the texture inspection model. Depending on which part of the training is affected by the corresponding parameter, either the whole training or only single steps have to be recalculated. This can lead to strong variations in the time required for retraining a texture inspection model. A precise description which parameters influence which parts of the algorithm are illustrated in set_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

**Parameters**

- `TextureInspectionModel` (input_control) texture_inspection_model ~ handle
  Handle of the texture inspection model.

**Example**

* Create texture inspection model
  create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
16.4. TEXTURE INSPECTION

```
set_texture_inspection_model_param (TextureInspectionModel, \n    'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \n    Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \n    TextureInspectionModel, \n    TextureInspectionResultID)
```

Result

The operator `train_texture_inspection_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- add_texture_inspection_model_image, set_texture_inspection_model_param

Possible Successors

- apply_texture_inspection_model, clear_texture_inspection_model,
- remove_texture_inspection_model_image, write_texture_inspection_model,
- serialize_texture_inspection_model

References

Module

### Matching

```
write_texture_inspection_model ( : : TextureInspectionModel, 
    FileName : )
```

Write a texture inspection model to a file.

`write_texture_inspection_model` writes the texture inspection model `TextureInspectionModel` to the file given by `FileName`. The default HALCON file extension for the texture inspection model is 'htim'. `write_texture_inspection_model` is typically called after the texture inspection model has been trained with `train_texture_inspection_model`. However, it can also be used to save an untrained model. The texture inspection model can be read with `read_texture_inspection_model`. It should be noted that `write_texture_inspection_model` does not write any training samples that possibly have been stored in the texture inspection model. Instead, only the currently set parameters of the model, possibly added images and, if trained, the classifiers of the single pyramid levels are written.
For an explanation of the concept of the texture inspection see the introduction of chapter *Inspection / Texture Inspection*.

### Parameters

- **TextureInspectionModel** (input_control) : texture_inspection_model  
  Handle of the texture inspection model.
- **FileName** (input_control) : filename.write  
  File name.
  **File extension**: .htim

### Example

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)

* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, 'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)

* Write out texture inspection model
write_texture_inspection_model (TextureInspectionModel, 'ExampleModel.htim')

### Result

If the parameters are valid, the operator **write_texture_inspection_model** returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

*Free the memory of the training data of a variation model.*
clear_train_data_variation_model frees the memory of a variation model that was created by **create_variation_model**. **clear_train_data_variation_model** can be used to reduce the amount of memory required for the variation model (in main memory as well as when writing the model to
file with `write_variation_model`). `clear_train_data_variation_model` can only be called if the model has been prepared for comparison with an image with `prepare_variation_model`. After the call to `clear_train_data_variation_model` the variation model can only be used for image comparison with `compare_variation_model` or `compare_ext_variation_model`. The model cannot be trained any further. Furthermore, the images used for the image comparison can no longer be read with `get_variation_model`. If they are required, `get_variation_model` must be called before `clear_train_data_variation_model` is called.

```plaintext
Parameters

- **ModelID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . variation_model ~ handle
  ID of the variation model.

Result

`clear_train_data_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

  During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- `prepare_variation_model`

Possible Successors

- `compare_variation_model, compare_ext_variation_model, write_variation_model`

Module

Matching

**clear_variation_model** ( : : ModelID : )

Free the memory of a variation model.

`clear_variation_model` frees the memory of a variation model that was created by `create_variation_model`. After calling `create_variation_model`, the model can no longer be used. The handle `ModelID` becomes invalid.

```plaintext
Parameters

- **ModelID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . variation_model ~ handle
  ID of the variation model.

Result

`clear_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_variation_model  

Module

Matching

**compare_ext_variation_model** (Image : Region : ModelID, Mode : )

Compare an image to a variation model.

`compare_ext_variation_model` compares the input image `Image` to the variation model given by `ModelID`. `compare_ext_variation_model` is an extension of `compare_variation_model` that provides more modes for the image comparison. Before `compare_ext_variation_model` can be called, the two internal threshold images of the variation model must have been created with `prepare_variation_model` or `prepare_direct_variation_model`. Let \( c(x, y) \) denote the input image `Image` and \( t_u, t_l \) denote the two threshold images (see `prepare_variation_model` or `prepare_direct_variation_model`). Then, for `Mode = 'absolute'` the output region `Region` contains all points that differ substantially from the model, i.e., the points that fulfill the following condition:

\[
  c(x, y) > t_u(x, y) \lor c(x, y) < t_l(x, y)
\]

This mode is identical to `compare_variation_model`. For `Mode = 'light'`, `Region` contains all points that are too bright:

\[
  c(x, y) > t_u(x, y)
\]

For `Mode = 'dark'`, `Region` contains all points that are too dark:

\[
  c(x, y) < t_l(x, y)
\]

Finally, for `Mode = 'light_dark'` two regions are returned in `Region`. The first region contains the result of `Mode = 'light'`, while the second region contains the result of `Mode = 'dark'`. The respective regions can be selected with `select_obj`.

**Parameters**

- **Image** (input_object)  
  singlechannelimage(-array)  
  Image of the object to be compared.

- **Region** (output_object)  
  region(-array)  
  Region containing the points that differ substantially from the model.

- **ModelID** (input_control)  
  variation_model  
  ID of the variation model.

- **Mode** (input_control)  
  string  
  Method used for comparing the variation model.
  Default value: 'absolute'
  Suggested values: `Mode ∈ { 'absolute', 'light', 'dark', 'light_dark' }`

**Example**

```plaintext
open_framegrabber ('File', 1, 1, 0, 0, 0, 0, 'default', -1, 
  'default', -1, 'default', 'testimages.seq', 'default', 
  -1, -1, AcqHandle)
read_region (Region, 'model.reg')
area_center (Region, Area, RowRef, ColumnRef)
read_shape_model ('model.shm', TemplateID)
read_variation_model ('model.var', ModelID)
for K := 1 to 10000 by 1
  grab_image (Image, AcqHandle)
  find_shape_model (Image, TemplateID, 0, rad(360), 0.5, 1, 0.5, 
```
16.5. VARIATION MODEL

'retrue', 4, 0.9, Row, Column, Angle, Score)  
dev_display (Image)  
if (|Score| == 1)  
  vector_angle_to_rigid (Row, Column, Angle, RowRef, \  ColumnRef, 0, HomMat2D)  
  affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', \  'false')  
  compare_ext_variation_model (ImageTrans, RegionDiff, ModelID, \  'light')  
endif  
dev_display (RegionDiff)  
endfor  
close_framegrabber (AcqHandle)

Result

compare_ext_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct  
and if the internal threshold images have been generated with prepare_variation_model  
or prepare_direct_variation_model.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

**compare_variation_model** ( Image : Region : ModelID : )

Compare an image to a variation model.

compare_variation_model compares the input image Image to the variation model given  
by ModelID. Before compare_variation_model can be called, the two internal threshold  
images of the variation model must have been created with prepare_variation_model  
or prepare_direct_variation_model. Let \( c(x,y) \) denote the input image Image and \( t_u,t \)  
denote the two threshold images (see prepare_variation_model or prepare_direct_variation_model).  
Then the output region Region contains all points that differ substantially from the model, i.e., the points  
that fulfill the following condition:

\[
c(x,y) > t_u(x,y) \lor c(x,y) < t_l(x,y) .
\]

If only too bright or too dark errors should be segmented the operator compare_ext_variation_model  
can be used.
Parameters

- **Image** (input_object) \(\ldots\) \(\sim\) object : byte / int2 / uint2
  Image of the object to be compared.

- **Region** (output_object) \(\ldots\) \(\sim\) object : region(-array)
  Region containing the points that differ substantially from the model.

- **ModelID** (input_control) \(\ldots\) \(\sim\) handle
  ID of the variation model.

Example

```haskell
open_framegrabber ('File', 1, 1, 0, 0, 0, 0, 'default', -1, \n  'default', -1, 'default', 'testimages.seq', 'default', \n  -1, -1, AcqHandle)
read_region (Region, 'model.reg')
area_center (Region, Area, RowRef, ColumnRef)
read_shape_model ('model.shm', TemplateID)
read_variation_model ('model.var', ModelID)
for K := 1 to 10000 by 1
  grab_image (Image, AcqHandle)
  find_shape_model (Image, TemplateID, 0, rad(360), 0.5, 1, 0.5, \n    'true', 4, 0.9, Row, Column, Angle, Score)
  dev_display (Image)
  if (|Score| == 1)
    vector_angle_to_rigid (Row, Column, Angle, RowRef, \n      ColumnRef, 0, HomMat2D)
    affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', \n      'false')
    compare_variation_model (ImageTrans, RegionDiff, ModelID)
    dev_display (RegionDiff)
  endif
endfor
close_framegrabber (AcqHandle)
```

Result

`compare_variation_model` returns `2 (H_MSG_TRUE)` if all parameters are correct and if the internal threshold images have been generated with `prepare_variation_model` or `prepare_direct_variation_model`.

16.5. VARIATION MODEL

`create_variation_model ( : Width, Height, Type, Mode : ModelID )`

Create a variation model for image comparison.

`create_variation_model` creates a variation model that can be used for image comparison. The handle for the variation model is returned in `ModelID`.

Typically, the variation model is used to discriminate correctly manufactured objects ("good objects") from incorrectly manufactured objects ("bad objects"). It is assumed that the discrimination can be done solely based on the gray values of the object.

The variation model consists of an ideal image of the object to which the images of the objects to be tested are compared later on with `compare_variation_model` or `compare_ext_variation_model`, and an image that represents the amount of gray value variation at every point of the object. The size of the images with which the object model is trained and with which the model is compared later on is passed in `Width` and `Height`, respectively. The image type of the images used for training and comparison is passed in `Type`.

The variation model is trained using multiple images of good objects. Therefore, it is essential that the training images show the objects in the same position and rotation. If this cannot be guaranteed by external means, the pose of the object can, for example, be determined by using matching (see `find_shape_model`). The image can then be transformed to a reference pose with `affine_trans_image`.

The parameter `Mode` is used to determine how the image of the ideal object and the corresponding variation image are computed. For `Mode='standard'`, the ideal image of the object is computed as the mean of all training images at the respective image positions. The corresponding variation image is computed as the standard deviation of the training images at the respective image positions. This mode has the advantage that the variation model can be trained iteratively, i.e., as soon as an image of a good object becomes available, it can be trained with `train_variation_model`. The disadvantage of this mode is that great care must be taken to ensure that only images of good objects are trained, because the mean and standard deviation are not robust against outliers, i.e., if an image of a bad object is trained inadvertently, the accuracy of the ideal object image and that of the variation image might be degraded.

If it cannot be avoided that the variation model is trained with some images of objects that can contain errors, `Mode` can be set to `robust`. In this mode, the image of the ideal object is computed as the median of all training images at the respective image positions. The corresponding variation image is computed as a suitably scaled median absolute deviation of the training images and the median image at the respective image positions. This mode has the advantage that it is robust against outliers. It has the disadvantage that it cannot be trained iteratively, i.e., all training images must be accumulated using `concat_obj` and be trained with `train_variation_model` in a single call.

In some cases, it is impossible to acquire multiple training images. In this case, a useful variation image cannot be trained from the single training image. To solve this problem, variations of the training image can be created synthetically, e.g., by shifting the training image by ±1 pixel in the row and column directions or by using gray value morphology (e.g., `gray_erosion_shape` and `gray_dilation_shape`), and then training the synthetically modified images. A different possibility to create the variation model from a single image is to create the model with `Mode='direct'`. In this case, the variation model can only be trained by specifying the ideal image and the variation image directly with `prepare_direct_variation_model`. Since the variation typically is large at the edges of the object, edge operators like `sobel_amp`, `edges_image`, or `gray_range_rect` should be used to create the variation image.

### Parameters

- **Width** (input_control) .......................................................... `extent.x ~ integer`
  - Width of the images to be compared.
  - **Default value:** 640
  - **Suggested values:** `Width ∈ {160, 192, 320, 384, 640, 768}`

- **Height** (input_control) ....................................................... `extent.y ~ integer`
  - Height of the images to be compared.
  - **Default value:** 480
  - **Suggested values:** `Height ∈ {120, 144, 240, 288, 480, 576}`

- **Type** (input_control) .......................................................... `string ~ string`
  - Type of the images to be compared.
  - **Default value:** `byte`
  - **Suggested values:** `Type ∈ {'byte', 'int2', 'uint2'}`
**Mode** (input_control) .......................... string  \( \sim \) string
Method used for computing the variation model.

**Default value:** 'standard'
**Suggested values:** \( \text{Mode} \in \{\text{\textquoteleft standard\textquoteleft}, \text{\textquoteleft robust\textquoteleft}, \text{\textquoteleft direct\textquoteleft}\}\)

**ModelID** (output_control) .......................... variation_model  \( \sim \) handle
ID of the variation model.

---

**Complexity**

A variation model created with `create_variation_model` requires \( 12 \times \text{Width} \times \text{Height} \) bytes of memory for `Mode = \text{\textquoteleft standard\textquoteleft}` and `Mode = \text{\textquoteleft robust\textquoteleft}` for `Type = \text{\textquoteleft byte\textquoteleft}`. For `Type = \text{\textquoteleft uint2\textquoteleft}` and `Type = \text{\textquoteleft int2\textquoteleft}`, \( 14 \times \text{Width} \times \text{Height} \) are required. For `Mode = \text{\textquoteleft direct\textquoteleft}` and after the training data has been cleared with `clear_train_data_variation_model`, \( 2 \times \text{Width} \times \text{Height} \) bytes are required for `Type = \text{\textquoteleft byte\textquoteleft}` and \( 4 \times \text{Width} \times \text{Height} \) for the other image types.

---

**Result**

create_variation_model returns 2 (H_Msg_TRUE) if all parameters are correct.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

---

**Possible Successors**

---

**deserialize_variation_model** ( : : SerializedItemHandle : ModelID )

**Deserialize a variation model.**

`deserialize_variation_model` deserializes a variation model, that was serialized by `serialize_variation_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized variation model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created variation model with the handle `ModelID`.

---

**Parameters**

- **SerializedItemHandle** (input_control) .......................... serialized_item  \( \sim \) handle
Handle of the serialized item.

- **ModelID** (output_control) .......................... variation_model  \( \sim \) handle
ID of the variation model.

---

**Result**

If the parameters are valid, the operator `deserialize_variation_model` returns the value 2 (H_Msg_TRUE). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_thresh_images_variation_model ( : MinImage, MaxImage : ModelID : )

Return the threshold images used for image comparison by a variation model.

get_thresh_images_variation_model returns the threshold images of the variation model ModelID in MaxImage and MinImage. The threshold images must be computed with prepare variation model or prepare direct variation model before they can be read out. The formula used for calculating the threshold images is described with prepare variation model or prepare direct variation model. The threshold images are used in compare variation model and compare ext variation model to detect too large deviations of an image with respect to the model. As described with compare variation model and compare ext variation model, gray values outside the interval given by MinImage and MaxImage are regarded as errors.

Parameters

- MinImage (output_object) ......................... image \( \sim \) object : byte / int2 / uint2
  Threshold image for the lower threshold.

- MaxImage (output_object) ......................... image \( \sim \) object : real
  Threshold image for the upper threshold.

- ModelID (input_control) .................................... variation_model \( \sim \) handle
  ID of the variation model.

Result

get_thresh_images_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
prepare variation model, prepare direct variation model

See also

get variation model, Module

Return the images used for image comparison by a variation model.

get variation model returns the image of the ideal object and the corresponding variation image of the variation model ModelID in Image and VarImage, respectively. The returned images can be used to check whether an image of a bad object has been trained with train variation model. This can be seen from the variation image. If an image of a bad object has been trained, the variation image typically has large variations in areas that should exhibit no variations.

HALCON 20.05.0.0
Parameters

- **Image** (output_object) : image → object : byte / int2 / uint2
  Image of the trained object.
- **VarImage** (output_object) : image → object : real
  Variation image of the trained object.
- **ModelID** (input_control) : variation_model → handle
  ID of the variation model.

Result

get_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- **train_variation_model**
- **prepare_variation_model**, **compare_variation_model**, **compare_ext_variation_model**

Module

Prepare a variation model for comparison with an image.

**prepare_direct_variation_model** (RefImage, VarImage : : ModelID,
AbsThreshold, VarThreshold : )

Prepare a variation model for comparison with an image. **prepare_direct_variation_model** prepares a variation model for the image comparison with **compare_variation_model** or **compare_ext_variation_model**. The variation model must have been created with Mode = 'direct' with **create_variation_model**. In contrast to **prepare_variation_model**, the ideal image of the object and the corresponding variation image are not computed with **train_variation_model**, but are specified directly in **RefImage** and **VarImage**. This is useful if the variation model should be created from a single image, as described with **create_variation_model**. The variation image should typically be created with edge operators like **sobel_amp**, **edges_image**, or **gray_range_rect**.

**prepare_direct_variation_model** converts the ideal image **RefImage** and the variation image **VarImage** into two threshold images and stores them in the variation model. These threshold images are used in **compare_variation_model** or **compare_ext_variation_model** to perform the comparison of the current image to the variation model.

Two thresholds are used to compute the threshold images. The parameter **AbsThreshold** determines the minimum amount of gray levels by which the image of the current object must differ from the image of the ideal object. The parameter **VarThreshold** determines a factor relative to the variation image for the minimum difference of the current image and the ideal image. **VarThreshold** utilizes **VarImage** to define regions, in which differences in gray values may occur which should not be counted as errors. This allows variations for specific parts of the object to inspect. **AbsThreshold** and **VarThreshold** each can contain one or two values. If two values are specified, different thresholds can be determined for too bright and too dark pixels. In this mode, the first value refers to too bright pixels, while the second value refers to too dark pixels. If one value is specified, this value refers to both the too bright and too dark pixels. Let \( i(x, y) \) be the ideal image **RefImage**, \( v(x, y) \) the variation image **VarImage**, \( a_u = \text{AbsThreshold}[0] \), \( a_l = \text{AbsThreshold}[1] \), \( b_u = \text{VarThreshold}[0] \), and \( b_l = \text{VarThreshold}[1] \) (or \( a_u = \text{AbsThreshold}, a_l = \text{AbsThreshold}, b_u = \text{VarThreshold}, \) and \( b_l = \text{VarThreshold} \), respectively). Then the two threshold images \( t_u, t_l \) are computed as follows:

\[
  t_u(x, y) = i(x, y) + \max\{a_u, b_u v(x, y)\} \quad t_l(x, y) = i(x, y) - \max\{a_l, b_l v(x, y)\}.
\]
If the current image \( c(x, y) \) is compared to the variation model using `compare_variation_model`, the output region contains all points that differ substantially from the model, i.e., that fulfill the following condition:

\[
c(x, y) > t_u(x, y) \lor c(x, y) < t_l(x, y)
\]

In `compare_ext_variation_model`, extended comparison modes are available, which return only too bright errors, only too dark errors, or bright and dark errors as separate regions.

After the threshold images have been created they can be read out with `get_thresh_images_variation_model`.

It should be noted that `RefImage` and `VarImage` are not stored as the ideal and variation images in the model to save memory in the model.

---

**Parameters**

- **RefImage** (input_object) ........................................ singlechannelimage \( \sim \) object : byte / int2 / uint2
  Reference image of the object.
- **VarImage** (input_object) ........................................ singlechannelimage \( \sim \) object : byte / int2 / uint2
  Variation image of the object.
- **ModelID** (input_control) ........................................ variation_model \( \sim \) handle
  ID of the variation model.
- **AbsThreshold** (input_control) ..................................... number(-array) \( \sim \) real / integer
  Absolute minimum threshold for the differences between the image and the variation model.
  Default value: 10
  Suggested values: \( \text{AbsThreshold} \in \{0, 5, 10, 15, 20, 30, 40, 50\} \)
  Restriction: \( \text{AbsThreshold} \geq 0 \)
- **VarThreshold** (input_control) ..................................... number(-array) \( \sim \) real / integer
  Threshold for the differences based on the variation of the variation model.
  Default value: 2
  Suggested values: \( \text{VarThreshold} \in \{1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5\} \)
  Restriction: \( \text{VarThreshold} \geq 0 \)

---

**Example**

```hcl
read_image (Image, 'model')
sobel_amp (Image, VarImage, 'sum_abs', 3)
get_image_pointer1 (Image, Pointer, Type, Width, Height)
create_variation_model (Width, Height, Type, 'direct', ModelID)
prepare_direct_variation_model (Image, VarImage, ModelID, 20, 1)
write_variation_model (ModelID, 'model.var')
```

---

**Result**

`prepare_direct_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

HALCON 20.05.0.0
prepare_variation_model

See also
create_variation_model

Module
Matching

prepare_variation_model ( : : ModelID, AbsThreshold,
   VarThreshold : )

Prepare a variation model for comparison with an image.

prepare_variation_model prepares a variation model for the image comparison with compare_variation_model or compare_ext_variation_model. This is done by converting the ideal image and the variation image that have been trained with train_variation_model into two threshold images and storing them in the variation model. These threshold images are used in compare_variation_model or compare_ext_variation_model to speed up the comparison of the current image to the variation model.

Two thresholds are used to compute the threshold images. The parameter AbsThreshold determines the minimum amount of gray levels by which the image of the current object must differ from the image of the ideal object. The parameter VarThreshold determines a factor relative to the variation image for the minimum difference of the current image and the ideal image. AbsThreshold and VarThreshold each can contain one or two values. If two values are specified, different thresholds can be determined for too bright and too dark pixels. In this mode, the first value refers to too bright pixels, while the second value refers to too dark pixels. If one value is specified, this value refers to both the too bright and too dark pixels. Let $i(x,y)$ be the ideal image, $v(x,y)$ the variation image, $a_u = \text{AbsThreshold}[0]$, $a_l = \text{AbsThreshold}[1]$, $b_u = \text{VarThreshold}[0]$, and $b_l = \text{VarThreshold}[1]$ (or $a_u = \text{AbsThreshold}$, $a_l = \text{AbsThreshold}$, $b_u = \text{VarThreshold}$, and $b_l = \text{VarThreshold}$, respectively). Then the two threshold images $t_{u,l}$ are computed as follows:

$$
t_u(x,y) = i(x,y) + \max\{a_u, b_u v(x,y)\} \\
t_l(x,y) = i(x,y) - \max\{a_l, b_l v(x,y)\} 
$$

If the current image $c(x,y)$ is compared to the variation model using compare_variation_model, the output region contains all points that differ substantially from the model, i.e., that fulfill the following condition:

$$
c(x,y) > t_u(x,y) \lor c(x,y) < t_l(x,y). 
$$

In compare_ext_variation_model, extended comparison modes are available, which return only too bright errors, only too dark errors, or bright and dark errors as separate regions.

After the threshold images have been created they can be read out with get_thresh_images_variation_model. Furthermore, the training data can be deleted with clear_train_data_variation_model to save memory.

- **Parameters**

  - **ModelID** (input_control) . . . . . . . . . . . . . . . . . . . . variation_model ~ handle ID of the variation model.
  - **AbsThreshold** (input_control) . . . . . . . . . . . . . . . . . . . . number(-array) ~ real / integer
    
  Absolute minimum threshold for the differences between the image and the variation model.

    Default value: 10

    Suggested values: AbsThreshold ∈ {0, 5, 10, 15, 20, 30, 40, 50}

    Restriction: AbsThreshold >= 0

  - **VarThreshold** (input_control) . . . . . . . . . . . . . . . . . . . . number(-array) ~ real / integer
    
  Threshold for the differences based on the variation of the variation model.

    Default value: 2

    Suggested values: VarThreshold ∈ {1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5}

    Restriction: VarThreshold >= 0

- **Result**

  prepare_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

read_variation_model ( : : FileName : ModelID )
Read a variation model from a file.
The operator read_variation_model reads a variation model, which has been written with
write_variation_model, from the file FileName. The default HALCON file extension for a variation
model is ’vam’.
Parameters
. FileName (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . filename.read ; string
File name.
File extension: .vam
. ModelID (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . variation_model ; handle
ID of the variation model.
Result
If the file name is valid, the operator read_variation_model returns 2 (H_MSG_TRUE). If necessary an
exception is raised.
Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific
operators even though the handle is used as an input parameter by those operators.

HALCON 20.05.0.0


**serialize_variation_model ( : : ModelID : SerializedItemHandle )**

Serialize a variation model.

serialize_variation_model serializes the data of a variation model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_variation_model is converted to a serialized item. The variation model is defined by the handle ModelID. The serialized variation model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_variation_model.

**Parameters**

- **ModelID** (input_control) variation_model ~ handle ID of the variation model.
- **SerializedItemHandle** (output_control) serialized_item ~ handle Handle of the serialized item.

**Result**

If the parameters are valid, the operator serialize_variation_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

Matching

**train_variation_model ( Images : : ModelID : )**

Train a variation model.

train_variation_model trains the variation model that is passed in ModelID with one or more images, which are passed in Images.

As described for create_variation_model, a variation model that has been created using the mode 'standard' can be trained iteratively, i.e., as soon as images of good objects become available, they can be trained with train_variation_model. The ideal image of the object is computed as the mean of all previous training images and the images that are passed in Images. The corresponding variation image is computed as the standard deviation of the training images and the images that are passed in Images.

If the variation model has been created using the mode 'robust', the model cannot be trained iteratively, i.e., all training images must be accumulated using concat_obj and be trained with train_variation_model in a single call. If any images have been trained previously, the training information of the previous call is discarded. The image of the ideal object is computed as the median of all training images passed in Images. The corresponding variation image is computed as a suitably scaled median absolute deviation of the training images and the median image.

**Attention**

At most 65535 training images can be trained.
16.5. VARIATION MODEL

---

**Parameters**

- **Images** (input_object) 
  - .singlechannelimage(-array) ~ object : byte / int2 / uint2
  - Images of the object to be trained.

- **ModelID** (input_control)
  - variation_model ~ handle
  - ID of the variation model.

---

**Example**

```c
open_framegraber ('File', 1, 1, 0, 0, 0, 0, 'default', -1, 
  'default', -1, 'default', 'model.seq', 'default', 
-1, -1, AcqHandle)
grab_image (Image, AcqHandle)

Legacy

17.1 2D Metrology

```
copy_metrology_object ( : : MetrologyHandle, 
                         Index : CopiedIndices )
```

Copy metrology metrology objects of a metrology model.

`copy_metrology_object` is obsolete and is only provided for reasons of backward compatibility.

`copy_metrology_object` copies metrology metrology objects within this metrology model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle `MetrologyHandle`. The parameter `Index` determines the metrology objects that are copied. With `Index` set to 'all', all metrology objects are copied. The operator `copy_metrology_object` returns the index of the new created metrology objects in the parameter `CopiedIndices`. The order of the new metrology objects corresponds to the order of the original metrology objects. Access to the parameters of the metrology objects of the metrology model is possible, e.g., with the operator `get_metrology_object_param`.

---

### Parameters

- **MetrologyHandle** (input_control) .......................... handle
  Handle of the metrology model.

- **Index** (input_control) ........................................ integer(-array)  \(\rightarrow\) string / integer
  Index of the metrology objects.
  
  **Default value:** 'all'
  **Suggested values:** Index \(\in\) {'all', 0, 1, 2}

- **CopiedIndices** (output_control) .............................. integer(-array)  \(\rightarrow\) integer
  Indices of the copied metrology objects.

---

### Result

If the parameters are valid, the operator `copy_metrology_object` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Module**

2D Metrology
**transform_metrology_object** ( : : MetrologyHandle, Index, Row, Column, Phi, Mode : )

Transform metrology objects of a metrology model, e.g. for alignment.

**transform_metrology_object** is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **align_metrology_model** instead.

**transform_metrology_object** translates and rotates the metrology objects contained in **MetrologyHandle** specified by the index **Index** according to the parameters **Row**, **Column**, and **Phi**.

For an explanation of the concept of 2D metrology see the introduction of chapter **2D Metrology**.

The index **Index** refer to the index returned by the operators **add_metrology_object_circle_measure**, **add_metrology_object_ellipse_measure**, **add_metrology_object_line_measure**, or **add_metrology_object_rectangle2_measure**. **Index** may contain a single value or a tuple of values. If all metrology objects shall be transformed, **Index** can be set to 'all'.

The parameter **Mode** can be set to 'absolute' or 'relative' and specifies the effect of the transformation:

- **Mode** = 'absolute': The metrology objects are translated to the image coordinates **Row** and **Column** and rotated by **Phi** with respect to the image coordinate system.
  
  For metrology objects of the type ellipse, or rectangle, the origin of the rotation is defined in the center of the metrology object as specified in the operators **add_metrology_object_ellipse_measure** or **add_metrology_object_rectangle2_measure**. For lines and circles, **Phi** is ignored.

- **Mode** = 'relative': The values of the transformation are considered as relative values, i.e., they are specified relative to the previous position and rotation of the metrology object.
  
  For metrology objects of the type ellipse, or rectangle, the origin of the rotation is defined in the center of the metrology object as specified in the operators **add_metrology_object_ellipse_measure**, or **add_metrology_object_rectangle2_measure**. For lines, the starting point of the line is used as origin of the rotation. For circles, **Phi** is ignored.

**transform_metrology_object** is fastest if no rotation is defined, the original and translated measure regions both lie completely within the image. In all other cases, the measure regions have to be newly generated, which is slower.

**Attention**

Note that any results (fitted geometric shapes) that have been generated by the operator **apply_metrology_model** before calling **transform_metrology_object** are discarded during the transformation.

**Parameters**

- **MetrologyHandle** (input_control) ............................................ metrology_model ↦ handle
  Handle of the metrology model.

- **Index** (input_control) ...................................................... integer(-array) ↦ string / integer
  Index of the metrology objects.

  Default value: 'all'

  Suggested values: Index ∈ {'all', 0, 1, 2}

- **Row** (input_control) ....................................................... real(-array) ↦ real / integer
  Translation in row direction.

- **Column** (input_control) .................................................... real(-array) ↦ real / integer
  Translation in column direction.

- **Phi** (input_control) ....................................................... real(-array) ↦ real / integer
  Rotation angle.

- **Mode** (input_control) .................................................... string(-array) ↦ string
  Mode of the transformation.

  Default value: 'absolute'

  Suggested values: Mode ∈ {'absolute', 'relative'}

**Result**

If the parameters are valid, the operator **transform_metrology_object** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

17.2. CLASSIFICATION

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

2D Metrology

## 17.2 Classification

```plaintext
clear_sampset ( : : SampKey : )
```

Free memory of a data set.

clear_sampset is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

clear_sampset frees the memory which was used for training data set having read by read_sampset. This memory is only reusable in combination with read_sampset.

---

### Parameters

- **SampKey** (input_control) .......................... feature_set => handle
  Number of the data set.

---

### Result

clear_sampset returns 2 (H_MSG_TRUE). An exception is raised if the key SampKey does not exist.

---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SampKey

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

```plaintext
close_class_box ( : : ClassifHandle : )
```

Destroy the classifier.

close_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.
close_class_box deletes the classifier and frees the used memory space. All the trained data will be lost. For saving this trained data you should use write_class_box before.

Parameters

▷ ClassifHandle (input_control) ................................. class_box ~> handle Handle of the classifier.

Result

close_class_box returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_class_box, enquire_class_box, learn_class_box

Module

Foundation

create_class_box (: : : ClassifHandle )

Create a new classifier.

create_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

create_class_box creates a new adaptive classifier. All operators which are explained in chapter classification refer to such a initialized classifier (of type 2). See learn_class_box for more details about the functionality of the classifier.

Parameters

▷ ClassifHandle (output_control) ................................. class_box ~> handle Handle of the classifier.

Result

create_class_box returns 2 (H_MSG_TRUE) if the parameter is correct. An exception is raised if a classifier with this name already exists or there is not enough memory.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

learn_class_box, enquire_class_box, write_class_box, close_class_box, clear_sampset

learn_class_box, enquire_class_box, close_class_box

Foundation

descript_class_box ( : : ClassifHandle, Dimensions : ClassIdx, BoxIdx, BoxLowerBound, BoxHigherBound, BoxNumSamplesTrain, BoxNumSamplesWrong )

Describe the classes of a box classifier.

descript_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

descript_class_box describes the classes of a box classifier. A box classifier uses a set of hyper cuboids (boxes) for every class. These boxes describe the distribution of the samples.

descript_class_box returns for every class (ClassIdx) the boundaries of every contained box (BoxIdx) from dimension 1 up to Dimensions (BoxLowerBound, BoxHigherBound) as well as the number of samples that were used during the learning phase to determine these boundaries at each dimension (BoxNumSamplesTrain). Furthermore, the number of samples that were assigned to the wrong class during the learning phase is returned in BoxNumSamplesWrong.

The boundary information of the boxes can be used to inspect the box classifier.

Parameters

▷ ClassifHandle (input_control) .......................... class_box ↣ handle Handle of the classifier.
▷ Dimensions (input_control) .......................... integer ↣ integer Highest dimension for output.
  Default value: 3
▷ ClassIdx (output_control) ......................... integer(-array) ↣ integer Indices of the classes.
▷ BoxIdx (output_control) ............................ integer(-array) ↣ integer Indices of the boxes.
▷ BoxLowerBound (output_control) ................. integer(-array) ↣ integer Lower bounds of the boxes (for each dimension).
▷ BoxHigherBound (output_control) .......... integer(-array) ↣ integer Higher bounds of the boxes (for each dimension).
▷ BoxNumSamplesTrain (output_control) .. integer(-array) ↣ integer Number of training samples that were used to define this box (for each dimension).
▷ BoxNumSamplesWrong (output_control) ...... integer(-array) ↣ integer Number of training samples that were assigned incorrectly to the box.

Result

descript_class_box returns 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

CHAPTER 17 LEGACY

Module

Foundation

deserialize_class_box ( : : ClassifHandle, SerializedItemHandle : )

Deserialize a serialized classifier.

deserialize_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

deserialize_class_box deserializes a classifier, that was serialized by serialize_class_box (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized classifier is defined by the handle SerializedItemHandle. The values of the current classifier, defined by the handle ClassifHandle, are overwritten.

Attention

All values of the classifier are going to be overwritten.

Parameters

▷ ClassifHandle (input_control) .......... handle
      Handle of the classifier.

▷ SerializedItemHandle (input_control) .......... handle
      Handle of the serialized item.

Result

If the parameters are valid, the operator deserialize_class_box returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

See also

create_class_box, serialize_class_box

Foundation

enquire_class_box ( : : ClassifHandle, FeatureList : Class )

Classify a tuple of attributes.

enquire_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

FeatureList is a tuple of any floating point- or integer numbers (attributes) which has to be assigned to a class with assistance of a previous trained (learn_class_box) classifier. It is possible to specify attributes as unknown by indicating the symbol ‘∗’ instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until ‘max’, are automatically supposed to be undefined.

See learn_class_box for more details about the functionality of the classifier.
You may call the operators `learn_class_box` and `enquire_class_box` alternately, so that it is possible to classify already in the phase of learning. This means you could see when a satisfying behavior had been reached.

### Parameters

- **ClassifHandle** (input_control) .............................. class_box ↦ handle
  Handle of the classifier.
- **FeatureList** (input_control) .............................. real-array ↦ real / integer / string
  Array of attributes which has to be classified.
  Default value: 1.0
- **Class** (output_control) .............................. integer ↦ integer
  Number of the class to which the array of attributes had been assigned.

### Result

`enquire_class_box` returns 2 (H_MSG_TRUE).

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `create_class_box`, `learn_class_box`, `set_class_box_param`

### Possible Successors

- `learn_class_box`, `write_class_box`, `close_class_box`

### Alternatives

- `enquire_reject_class_box`

### See also

- `test_sampset_box`, `learn_class_box`, `learn_sampset_box`

### Module

**Foundation**

```c
enquire_reject_class_box ( : : ClassifHandle,  
  FeatureList : Class )
```

Classify a tuple of attributes with rejection class.

**enquire_reject_class_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**FeatureList** is a tuple of any floating point- or integer numbers (attributes) which has to be assigned to a class with assistance of a previous trained (`learn_class_box`) classifier. It is possible to specify attributes as unknown by indicating the symbol ‘*’ instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until ‘max’, are automatically supposed to be undefined.

If the array of attributes cannot be assigned to a class, i.e. the array does not reside inside of one of the hyper boxes, then in contrary to `enquire_class_box` not the next class is going to be returned, but the rejection class -1 as a result is going to be passed.

See `learn_class_box` for more details about the functionality of the classifier.

You may call the operators `learn_class_box` and `enquire_class_box` alternately, so that it is possible to classify already in the phase of learning. By this means you could see when a satisfying behavior had been reached.

### Parameters

- **ClassifHandle** (input_control) .............................. class_box ↦ handle
  Handle of the classifier.
- **FeatureList** (input_control) .............................. real-array ↦ real / integer / string
  Array of attributes which has to be classified.
  Default value: 1.0
Class (output_control) .......................................................... integer \rightarrow integer
  Number of the class, to which the array of attributes had been assigned or -1 for the rejection class.

enquire_reject_class_box returns 2 (H_MSG_TRUE).

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
create_class_box, learn_class_box, set_class_box_param

Possible Successors
learn_class_box, write_class_box, close_class_box

enquire_class_box

Alternatives

Module

get_class_box_param ( : : ClassifHandle, Flag : Value )

Get information about the current parameter.

get_class_box_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

get_class_box_param gets the parameter of the classifier. The meaning of the parameter is explained in set_class_box_param.

Default values:
'\text{min\_samples\_for\_split}' = 80,
'split\_error' = 0.1,
'prop\_constant' = 0.25

Parameters

• ClassifHandle (input_control) .............................................. class\_box \rightarrow handle
  Handle of the classifier.

• Flag (input_control) ...................................................... string \rightarrow string
  Name of the system parameter.
  Default value: 'split\_error'
  List of values: Flag \in \{'split\_error', 'prop\_constant', 'used\_memory', 'min\_samples\_for\_split'\}

• Value (output_control) ................................................... number \rightarrow \text{real} / \text{integer}
  Value of the system parameter.

get_class_box_param returns 2 (H_MSG_TRUE). An exception is raised if Flag has been set with wrong values.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

---

**learn_class_box** ( : : ClassifHandle, Features, Class : )

*Train the classifier.*

**learn_class_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**Features** is a tuple of any floating point numbers or integers (attributes) which has to be assigned to the class **Class**. This class is specified by an integer. You may use the operator **enquire_class_box** later to find the most probable class for any array (= tupel). The algorithm tries to describe the set of arrays of one class by hyper cuboids in the feature space. On demand you may even create several cuboids per class. Hence it is possible to learn disjunct concepts, too. I.e such concepts which split in several “cluster” of points in the feature space. The data structure is hidden to the user and only accessible with such operators which are described in this chapter.

Note that if a class consists of disjunct sub-classes that would lead to a splitting of the respective hyper cuboid, the training samples should be in random order with respect to the sub-classes. Otherwise, the splitting of the hyper cuboid will be sub-optimal.

It is possible to specify attributes as unknown by indicating the symbol ’∗’ instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until ’max’, are automatically supposed to be undefined.

You may call the operators **learn_class_box** and **enquire_class_box** alternately, so that it is possible to classify already in the phase of learning. By this means you could see when a satisfying behavior had been reached.

The classifier is going to be bigger using further training. This means, that it is not advisable to continue training after reaching a satisfactory behavior.

**Parameters**

- **ClassifHandle** (input_control) ................................................. class_box  \( \Rightarrow \) handle
  Handle of the classifier.

- **Features** (input_control) .................................................. number-array  \( \Rightarrow \) real / integer / string
  Array of attributes to learn.
  Default value: [1.0,1.5,2.0]

- **Class** (input_control) ....................................................... integer  \( \Rightarrow \) integer
  Class to which the array has to be assigned.
  Default value: 1

**Result**

**learn_class_box** returns 2 (H_MSG_TRUE) for a normal case. An exception is raised if there are memory allocation problems. The number of classes is constrained. If this limit is passed, an exception is raised, too.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_class_box, enquire_class_box

Possible Successors
test_sampset_box, enquire_class_box, write_class_box, close_class_box, clear_sampset

Module
Foundation

**learn_sampset_box** ( : : ClassifHandle, SampKey, Outfile, NSamples, StopError, ErrorN : )

Train the classifier with one data set.

**learn_sampset_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**learn_sampset_box** trains the classifier with data for the key **SampKey** (see **read_sampset**). The training sequence is terminated at least after **NSamples** examples. If **NSamples** is bigger than the number of examples in **SampKey**, then a cyclic start at the beginning occurs. If the error underpasses the value **StopError**, then the training sequence is prematurely terminated. **StopError** is calculated with \( N / \text{ErrorN} \). Whereby \( N \) means the number of examples which were wrong classified during the last **ErrorN** training examples. Typically **ErrorN** is the number of examples in **SampKey** and **NSamples** is a multiple of it. If you want a data set with 100 examples to run 5 times at most and if you want it to terminate with an error lower than 5%, then the corresponding values are **NSamples** = 500, **ErrorN** = 100 and **StopError** = 0.05. A protocol of the training activity is going to be written in file **Outfile**.

**Parameters**

- **ClassifHandle** (input_control) . . . . . . . . . . . . . class_box \( \rightsquigarrow \) handle
  Handle of the classifier.
- **SampKey** (input_control) . . . . . . . . . . . . . feature_set \( \rightsquigarrow \) handle
  Number of the data set to train.
- **Outfile** (input_control) . . . . . . . . . . . . . filename.write \( \rightsquigarrow \) string
  Name of the protocol file.
  Default value: ‘training_prot’
- **NSamples** (input_control) . . . . . . . integer \( \rightsquigarrow \) integer
  Number of arrays of attributes to learn.
  Default value: 500
- **StopError** (input_control) . . . . . . . real \( \rightsquigarrow \) real
  Classification error for termination.
  Default value: 0.05
- **ErrorN** (input_control) . . . . . . . integer \( \rightsquigarrow \) integer
  Error during the assignment.
  Default value: 100

**Result**

learn_sampset_box returns 2 (H_MSG_TRUE). An exception is raised if key **SampKey** does not exist or there are problems while opening the file.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**read_class_box** ( : : ClassifHandle, FileName : )

Read a classifier from a file.

declare_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

read_class_box reads the saved classifier from the file FileName (see write_class_box). The values of the current classifier are overwritten. The default HALCON file extension for the box classifier is 'gbc'.

Attention All values of the classifier are going to be overwritten.

Parameters

▶ ClassifHandle (input_control) ................................................. class_box ⇒ handle
  Handle of the classifier.

▶ FileName (input_control) ................................................. filename.read ⇒ string
  Filename of the classifier.

File extension: .gbc

Result

read_class_box returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file FileName or the file has the wrong format.

---

**Parallelization**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

• Multithreading scope: global (may be called from any thread).

• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**read_sampset** ( : : FileName : SampKey )

Read a training data set from a file.

read_sampset is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

The training examples are accessible with the key **SampKey** by calling the operators **clear_sampset** and **learn_sampset_box**. You may edit the file using an editor. Every row contains an array of attributes with corresponding class. An example for a format might be:

\[(1.0, 25.3, *, 17 | 3)\]

This row specifies an array of attributes which belong to class 3. In this array the third attribute is unknown. Attributes upwards 5 are supposed to be unknown, too. You may insert comments like /* .. */ in any place.

### Parameters

- **FileName** (input_control) 
  Filenames of the data set to train. 
  **Default value:** 'sampset1'
- **SampKey** (output_control) 
  Identification of the data set to train.

### Result

read_sampset returns 2 (H_MSG_TRUE). An exception is raised if it is not possible to open the file or it contains syntax errors or there is not enough memory.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Predecessors

### See also

serialize_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**serialize_class_box** ( : : ClassifHandle : SerializedItemHandle )

Serialize a classifier.

serialize_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.
serialize_class_box serializes a classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_class_box is converted to a serialized item. The classifier is defined by the handle ClassifHandle. The serialized classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_class_box.

Parameters

- ClassifHandle (input_control) ... class_box ~(handle)
  Handle of the classifier.
- SerializedItemHandle (output_control) ... serialized_item ~(handle)
  Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_class_box returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_class_box, enquire_class_box, learn_class_box, test_sampset_box

create_class_box, deserialize_class_box

Module

Foundation

set_class_box_param ( : : ClassifHandle, Flag, Value : )

Set system parameters for classification.

set_class_box_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

set_class_box_param modifies parameter which manipulate the training sequence while calling learn_class_box. Only parameters of the classifier are modified, all other classifiers remain unmodified. 'min_samples_for_split' is the number of examples at least which have to train in one cuboid of this classifier, before the cuboid is allowed to divide itself. 'split_error' indicates the critical error. By its exceeding the cuboid divides itself, if there are more than 'min_samples_for_split' examples to train. 'prop_constant' manipulates the extension of the cuboids. It is proportional to the average distance of the training examples in this cuboid to the center of the cuboid. More detailed:

\[ \text{extension} \times \text{prop} = \text{average distance of the expectation value}. \]

This relation is valid in every dimension. Hence inside a cuboid the dimensions of the feature space are supposed to be independent.

The parameters are set with problem independent default values, which must not modified without any reason. Parameters are only important during a learning sequence. They do not influence on the behavior of enquire_class_box.

Default setting:

- 'min_samples_for_split' = 80,
- 'split_error' = 0.1,
- 'prop_constant' = 0.25
Parameters

- **ClassifHandle** (input_control) class_box \( \rightarrow \) handle
  Handle of the classifier.

- **Flag** (input_control) string \( \rightarrow \) string
  Name of the wanted parameter.
  Default value: 'split_error'
  Suggested values: Flag \( \in \) {'min_samples_for_split', 'split_error', 'prop_constant'}

- **Value** (input_control) number \( \rightarrow \) real / integer
  Value of the parameter.
  Default value: 0.1

**read_sampset** returns 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ClassifHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_class_box, enquire_class_box

Possible Successors

learn_class_box, test_sampset_box, write_class_box, close_class_box, clear_sampset

See also

enquire_class_box, get_class_box_param, learn_class_box

Module

Foundation

**test_sampset_box** ( : : ClassifHandle, SampKey : Error )

Classify a set of arrays.

test_sampset_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

In contrast to **learn_sampset_box** there is not a learning here. Typically you use **test_sampset_box** to classify independent test data. **Error** gives you information about the applicability of the learned training set on new examples.

Parameters

- **ClassifHandle** (input_control) class_box \( \rightarrow \) handle
  Handle of the classifier.

- **SampKey** (input_control) feature_set \( \rightarrow \) handle
  Key of the test data.

- **Error** (output_control) real \( \rightarrow \) real
  Error during the assignment.

test_sampset_box returns 2 (H_MSG_TRUE). An exception is raised, if if key **SampKey** does not exist or problems occur while opening the file.
17.2. CLASSIFICATION

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```plaintext
write_class_box ( : : ClassifHandle, FileName : )
```

Save a classifier in a file.

write_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

write_class_box writes the classifier ClassifHandle to the file given by FileName. The classifier can be read with read_class_box. The default HALCON file extension for the box classifier is `gbc`.

Attention

If a file with this name exists, it is overwritten without a warning. The file can not be edited.

Parameters

- **ClassifHandle** (input_control) Handle of the classifier.
- **FileName** (input_control) Name of the file which contains the written data.

File extension: .gbc

Result

write_class_box returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file FileName.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

HALCON 20.05.0.0
17.3 Control

```plaintext
ifelse ( : : Condition : )
```

Conditional statement with alternative.

`ifelse` is obsolete and is only provided for reasons of backward compatibility. `if` should be used instead.

`ifelse` is a conditional statement with an alternative. If the condition is true (i.e., not 0), all expressions and calls between the head and operator `else` are performed. If the condition is false (i.e., 0) the part between `else` and `endif` is executed. Note that the operator is called `ifelse` and it is displayed as `if` in the program text area.

- **Parameters**

  - `Condition` (input_control) .............................................. integer \sim integer
    
    Condition for the if statement.
    
    Default value: 1

  - **Result**

    If the condition is correct `ifelse` (as operator) returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

- **Alternatives**

  - `if` See also

  - `else, elseif, for, while, repeat, until`

17.4 DL Classification

The workflow and operators described in this chapter are obsolete and only provided for reasons backward compatibility. New applications should use the workflow and operators described in Deep Learning / Classification.

This chapter explains how to use classification based on deep learning, both for the training and inference phases.

**General Workflow**

This section describes the main steps and the workflow for classification with Deep Learning using the obsolete workflow.

**Prepare the Network and the Data** This part is about how to prepare and preprocess your data.

1. First, a pretrained network has to be read using the operator

   - `read_dl_classifier`

   This operator is used as well when you want to read your own trained networks, after you saved them with `write_dl_classifier`.

2. To read the data for your deep learning classification training the procedure

   - `read_dl_classifier_data_set`

   is available. Using this procedure you can get a list of image file paths and their respective labels (the ground truth labels) as well as a list of the unique classes, to which at least one of the listed images belongs.

3. The network will impose several requirements on the images, as the image dimensions and the gray value range. The default values are listed in `read_dl_classifier`. These are the values with which the networks have been pretrained. The network architectures allow different image dimensions, which can be set with `set_dl_classifier_param`, but depending on the network a change may make a retraining necessary. The actually set values can be retrieved with
17.4. DL CLASSIFICATION

The procedure `preprocessdl_classifier_images` provides great guidance on how to implement such a preprocessing stage. We recommend to preprocess and store all images used for the training before starting the classifier training, since this speeds up the training significantly.

4. Next, we recommend to split the dataset into three distinct datasets which are used for training, validation, and testing, see the section “Data” in the chapter Deep Learning. This can be achieved using the procedure

   • `splitdl_classifier_dataset`

5. You need to specify the 'classes' (determined before by use of `readdl_classifier_dataset`) you want to differentiate with your classifier. For this, the operator

   • `setdl_classifier_param`

is available.

This operator can also be used to set hyperparameters, which are important for training, e.g., 'batch_size' and 'learning_rate'. For a more detailed explanation, see the chapter Deep Learning and the documentation of `setdl_classifier_param`.

**Train the Network and Evaluate the Training Progress** Once your network is set up and your data prepared it is time to train the classifier for your specific task.

1. Set the hyperparameters used for training with the operator

   • `setdl_classifier_param`

   For an overview of possible hyperparameters, see the documentation of `setdl_classifier_param`. Additional explanations can be found in the chapter Deep Learning.

2. To train the classifier the operator

   • `traindl_classifier_batch`

is available. The intermediate training results are stored in the output handle.

As the name of `traindl_classifier_batch` indicates, this operator processes a batch of data (images and ground truth labels) at once. We iterate through our training data in order to train the classifier successively with `traindl_classifier_batch`. You can repeat this process multiple times and iterate over so many training epochs until you are satisfied with the training result.

3. To know how well the classifier learns the new task, the procedure

   • `plotdl_classifier_training_progress`

is provided. With it you can plot the classification errors during training. To compute the input necessary for the visualization, the procedures

   • `select_percentage_dl_classifier_data`,
   • `applydl_classifier_batchwise`, and
   • `evaluadedl_classifier`

are available. With them you can reduce the number of images used for this classification validation, apply the classifier on the selected data and compute, for example, the top-1 error.

**Apply and Evaluate the Final Classifier** Your classifier is trained for your task and ready to be applied. But before deploying in the real world you should evaluate how well the classifier performs on basis of your test data.

1. To apply the classifier on a set containing an arbitrary number of images, use the operator

   • `applydl_classifier`

The runtime of this operator depends on the number of batches needed for the given image set. The results are returned in a handle.

To retrieve the predicted classes and confidences, use the operator

• `getdl_classifier_result`. 
2. Now it is time to evaluate these results. The performance of the classifier can be evaluated as during the training with `evaluate_dl_classifier`.

To visualize and analyze the classifier quality, the confusion matrix is a useful tool (see below for an explanation). For this, you can use the procedures

- `gen_confusion_matrix`
- `gen_interactive_confusion_matrix`.

The interactive procedure gives you the possibility to select examples of a specific category, but it does not work with exported code.

Additionally, after applying the classifier on a set of data, you can use the procedure

- `get_dl_classifier_image_results`

to display and return images according to certain criteria, e.g., wrongly classified ones. Then, you might want to use this input for the procedure

- `dev_display_dl_classifier_heatmap`

to display a heatmap of the input image, with which you can analyze which regions of the image are relevant for the classification result.

**Inference Phase** When your classifier is trained and you are satisfied with its performance, you can use it to classify new images. For this, you simply preprocess your images according to the network requirements (i.e., the same way as you did for your dataset used for training the classifier) and apply the classifier using

- `apply_dl_classifier`.

**Data for Classification**

We distinguish between data used for training and data for inference. Latter one consists of bare images. But for the former one you already know to which class the images belong and provide this information over the corresponding labels.

The training data is used to train a classifier for your specific task. With the aid of this data the classifier can learn which classes are to be distinguished and how their representatives look like. In classification, the image is classified as a whole. Therefore, the training data consists of images and their ground truth labels, thus the class you say this image belongs to. Note that the images should be as representative as possible for your task. There are different possible ways, how to store and retrieve the ground truth labels. The procedure `read_dl_classifier_data_set` supports the following sources of the ground truth label for an image:

- The last folder name containing the image
- The file name.

For training a classifier, we use a technique called transfer learning (see the chapter *Deep Learning*). For this, you need less resources, but still a suitable set of data which is generally in the order of hundreds to thousands per class. While in general the network should be more reliable when trained on a larger dataset, the amount of data needed for training also depends on the complexity of the task. You also want enough training data to split it into three subsets, which are preferably independent and identically distributed, see the section “Data” in the chapter *Deep Learning*.

Regardless of the application, the network poses requirements on the images regarding the image dimensions, the gray value range, and the type. The specific values depend on the network itself and can be queried with `get_dl_classifier_param`. You can find guidance on how to implement such a preprocessing stage by the procedure `preprocess_dl_classifier_images`.

```python
apply_dl_classifier ( Images : DLClassifierHandle : DLClassifierResultHandle )
```

Infer the class affiliations for a set of images using a deep-learning-based classifier.

*apply_dl_classifier* is obsolete and is only provided for reasons of backward compatibility. New applications should use the general CNN-based operator *apply_dl_model* instead.
apply_dl_classifier applies the deep-learning-based classifier given by DLClassifierHandle on the set of input images stored in the input object tuple Images. It returns the results in the result handle DLClassifierResultHandle. For information how to retrieve the corresponding results stored in DLClassifierResultHandle, please refer to the documentation of the operator get_dl_classifier_result.

The tuple Images can contain an arbitrary number of images to be processed in one operator call and is generally independent of the classifier parameter 'batch_size'. Please notice that this only holds for apply_dl_classifier and not for train_dl_classifier_batch. This is because apply_dl_classifier always classifies a batch with up to 'batch_size' images simultaneously, whether filled up or not. So in case the number of images in the set Images is larger than 'batch_size', apply_dl_classifier iterates over the necessary number of batches internally. For a Images tuple with less than 'batch_size' images, it is padded to a full batch which means that the runtime of processing for a given batch is independent of whether it is filled up or just consists of a single image. Additionally, if fewer images than 'batch_size' are classified in one operator call, the network still requires the same amount of memory as for a full batch. Therefore, it is recommended to adapt the 'batch_size' according to the number of images to be processed in one operator call for greater efficiency. The current value of 'batch_size' can be retrieved using get_dl_classifier_param.

Note that the images must be processed before feeding them into the operator apply_dl_classifier in order to have the correct size, gray value range, number of channels and type. We would like to stress the image type: the images must be of type 'real'. For a possibly necessary conversion the operator convert_image_type is available. The procedure preprocess_dl_classifier_images provides great guidance on how to implement such a preprocessing stage.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

To run this operator, cuDNN and cuBLAS are required when 'runtime' is set to 'gpu', see set_dl_classifier_param. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning".

### Parameters

- **Images** (input_object) ........................................ (multichannel-)image(-array)  \(\leadsto\) object : real
  Tupel of input images.
- **DLClassifierHandle** (input_control) ............................. dl_classifier \(\leadsto\) handle
  Handle of the deep-learning-based classifier.
- **DLClassifierResultHandle** (output_control) .................... dl_classifier_result \(\leadsto\) handle
  Handle of the deep learning classification results.

If the parameters are valid, the operator apply_dl_classifier returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Predecessors

read_dl_classifier, train_dl_classifier_batch, set_dl_classifier_param

Deep Learning Inference
**clear\_dl\_classifier** (: : DLClassifierHandle : )

Clear a deep-learning-based classifier.

**clear\_dl\_classifier** is obsolete and is only provided for reasons of backward compatibility. New applications should use the common used CNN-based operator **clear\_dl\_model** instead.

**clear\_dl\_classifier** clears the handle of the deep-learning-based classifier given by **DLClassifierHandle**, that was created with **read\_dl\_classifier**, and frees all memory required for the classifier. After calling **clear\_dl\_classifier**, the classifier can no longer be used. The handle **DLClassifierHandle** becomes invalid.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

---

**Parameters**

- **DLClassifierHandle** (input\_control) .................. dl\_classifier(-array) ↦ handle
  Handle of the deep-learning-based classifier.

---

**Result**

If the parameters are valid, the operator **clear\_dl\_classifier** returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**read\_dl\_classifier, apply\_dl\_classifier, train\_dl\_classifier\_batch**

---

**Module**

Deep Learning Inference

---

**clear\_dl\_classifier\_result** (: : DLClassifierResultHandle : )

Clear a handle containing the results of the deep-learning-based classification.

**clear\_dl\_classifier\_result** is obsolete and is only provided for reasons of backward compatibility.

**clear\_dl\_classifier\_result** releases the memory used to store the deep-learning-based classification results given in **DLClassifierResultHandle**. After calling **clear\_dl\_classifier\_result**, the results can no longer be queried. The handle **DLClassifierResultHandle** becomes invalid.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

---

**Parameters**

- **DLClassifierResultHandle** (input\_control) .................. dl\_classifier\_result(-array) ↦ handle
  Handle of the deep learning classification results.

---

**Result**

If the parameters are valid, the operator **clear\_dl\_classifier\_result** returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
17.4. DL CLASSIFICATION

- Processed without parallelization.

Possible Predecessors

get_dl_classifier_result, apply_dl_classifier

Module

Deep Learning Inference

clear_dl_classifier_train_result (  
: : DLClassiferTrainResultHandle : )

Clear the handle of a deep-learning-based classifier training result.

clear_dl_classifier_train_result is obsolete and is only provided for reasons of backward compatibility.

clear_dl_classifier_train_result clears an arbitrary number of training result handles DLClassiferTrainResultHandle of a deep-learning-based classifier. Each of these training result handles has previously been generated using train_dl_classifier_batch. All memory allocated in the handles is freed.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

- DLClassiferTrainResultHandle (input_control) ...... dl_classifier_train_result(-array) \sim handle
  Handle of the training results from the deep-learning-based classifier.

Result

If the parameters are valid, the operator clear_dl_classifier_train_result returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

train_dl_classifier_batch, get_dl_classifier_train_result

Module

Deep Learning Training

deserialize_dl_classifier (  
: : SerializedItemHandle : DLClassiferHandle )

Deserialize a deep-learning-based classifier.

deserialize_dl_classifier is obsolete and is only provided for reasons of backward compatibility.

New applications should use the common CNN-based operator deserialize_dl_model.

deserialize_dl_classifier deserializes a deep-learning-based classifier, that was serialized by serialize_dl_classifier.

The operator acts the same as read_dl_classifier except that the input is a serialized item instead of a file. For a detailed description please refer to the documentation of read_dl_classifier.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
### Parameters

- **SerializedItemHandle** (input_control) 
  Handle of the serialized item.
- **DLClassifierHandle** (output_control) 
  Handle of the deep-learning-based classifier.

### Result

If the parameters are valid, the operator `deserialize_dl_classifier` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `fread_serialized_item`
- `receive_serialized_item`
- `serialize_dl_classifier`

### Possible Successors

- `apply_dl_classifier`
- `train_dl_classifier_batch`
- `set_dl_classifier_param`
- `get_dl_classifier_param`

### Alternatives

- `deserialize_dl_model`

### See also

### Module

Deep Learning Inference

---

```haskell
get_dl_classifier_param ( : : DLClassifierHandle, 
                         GenParamName : GenParamValue )
```

Return the parameters of a deep-learning-based classifier.

`get_dl_classifier_param` is obsolete and is only provided for reasons of backward compatibility. New applications should use common CNN-based operator `get_dl_model_param` instead.

`get_dl_classifier_param` returns the parameter values `GenParamValue` of `GenParamName` of the neural network `DLClassifierHandle`.

The hyperparameters and network parameters can be set with the operator `set_dl_classifier_param`, in whose reference entry they are described in detail. With `get_dl_classifier_param` you can query all these values.

Additionally, there are parameters defined by the network which are read-only. These parameters are:

- `'image_range_min'`: Minimum gray value.
- `'image_range_max'`: Maximum gray value.

The precise values for these parameters and the default parameters for the image dimension depend on the concrete network, see `read_dl_classifier`.

Every image that is fed into the network must be present according to the parameters defining the image properties. To preprocess images accordingly, the procedure `preprocess_dl_classifier_images` is available.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
17.4. DL CLASSIFICATION

Parameters

- **DLClassifierHandle** (input_control) ................. dl_classifier ~ handle
  Handle of the deep-learning-based classifier.

- **GenParamName** (input_control) ..................... attribute.name(-array) ~ string
  Name of the generic parameter.
  Default value: 'gpu'
  List of values: GenParamName ∈ {'batch_size', 'batch_size_multiplier', 'classes', 'gpu',
  'image_dimensions', 'image_num_channels', 'image_height', 'image_range_max', 'image_range_min',
  'image_width', 'learning_rate', 'momentum', 'runtime', 'runtime_init', 'weight_prior'}

- **GenParamValue** (output_control) ................. attribute.name(-array) ~ integer / string / real
  Value of the generic parameter.

Result

If the parameters are valid, the operator `get_dl_classifier_param` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_dl_classifier`, `set_dl_classifier_param`

Possible Successors

`train_dl_classifier_batch`, `apply_dl_classifier`

Alternatives

See also

`set_dl_classifier_param`

Module

Deep Learning Inference

---

**get_dl_classifier_result** ( : : DLClassifierResultHandle, Index,
GenResultName : GenResultValue )

Retrieve classification results inferred by a deep-learning-based classifier.

**get_dl_classifier_result** is obsolete and is only provided for reasons of backward compatibility.

**get_dl_classifier_result** allows the user to return classification results. These results are stored in the handle `DLClassifierResultHandle` and have been obtained from the operator `apply_dl_classifier`.

The input parameter **GenResultName** names the sort of result asked and **Index** identifies for which image the result is to be returned. The respective value is given in **GenResultValue**.

Concretely, **GenResultName** can attain the following values:

- 'confidences': return the confidences values for the selected image **Index**.
- 'predicted_classes': return the names of the inferred classes for the selected image **Index**.
- 'predicted_class_indices': return the indices of the inferred classes for the selected image **Index**. The class indices correspond to the positions within the array of classes (counting from 0).

The input parameter **Index** can attain the value 'all', in which case **get_dl_classifier_result** returns the confidence value, respectively class, for the best candidate (prediction with the highest confidence value) for each image of the input batch.
Otherwise, Index must be an integer selecting one of the input images in the batch, in which case get_dl_classifier_result returns all output classes, respectively, confidences sorted by decreasing confidence value. This is useful in order to retrieve the best K candidates for a given input. As we start indexing at 0, Index must have a value between 0 and the size of the batch of input images minus one.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

瘠 DLClassifierResultHandle (input_control) .......................... dl_classifier_result ～ handle
Handle of the deep learning classification results.

瘠 Index (input_control) .................................................... number ～ string / integer
Index of the image in the batch.
Default value: ‘all’

瘠 GenResultName (input_control) ................................... attribute.name(-array) ～ string
Name of the generic parameter.
Default value: ‘predicted_classes’
List of values: GenResultName ∈ [‘predicted_classes’, ‘predicted_class_indices’, ‘confidences’]

瘠 GenResultValue (output_control) ................................. attribute.value(-array) ～ real / string / integer
Value of the generic parameter, either the confidence values, the class names or class indices.

Result

If the parameters are valid, the operator get_dl_classifier_result returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Deep Learning Inference

get_dl_classifier_train_result ( : : DLClassifierTrainResultHandle, GenParamName : GenParamValue )

Return the results for the single training step of a deep-learning-based classifier.

get_dl_classifier_train_result is obsolete and is only provided for reasons of backward compatibility.

get_dl_classifier_train_result returns the value GenParamValue of the result GenParamName of a deep learning training handle DLClassifierTrainResultHandle.

The options for GenParamValue are the following:

‘loss’ or ‘total_loss’: Current value of the loss function. See train_dl_classifier_batch for a detailed explanation of the loss function.

‘mll_loss’: Current value of the loss function, i.e. ‘loss’, without ‘regularization_loss’.

‘regularization_loss’: Current value of the regularization loss function, i.e. ‘loss’ without ‘mll_loss’.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
17.4. DL CLASSIFICATION

Parameters

**DLClassifierTrainResultHandle** (input_control) .......... dl_classifier_train_result \(\rightarrow\) handle
Handle of the training results from the deep-learning-based classifier.

**GenParamName** (input_control) . . . . . . . . . . . . . attribute.name(-array) \(\rightarrow\) string
Name of the generic parameter.

**Default value**: 'loss'
**List of values**: GenParamName \(\in\) {'loss', 'mll_loss', 'regularization_loss', 'total_loss'}

**GenParamValue** (output_control) . . . . . . . . . . . . . attribute.name(-array) \(\rightarrow\) real / integer / string
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_dl_classifier_train_result` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Deep Learning Training

**read_dl_classifier** ( : : FileName : DLClassifierHandle )

Read a deep-learning-based classifier from a file.

**read_dl_classifier** is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **read_dl_model**.

The operator **read_dl_classifier** reads a neural network written by **write_dl_classifier**. As a result, the handle **DLClassifierHandle** is returned.

HALCON provides pretrained neural networks. These neural networks are good starting points to train a custom classifier for image classification. They have been pretrained on a large image dataset. The provided pretrained neural networks are:

- **'pretrained_dl_classifier_compact.hdl'**: This neural network is designed to be memory and runtime efficient. This classifier expects the images to be of the type 'real'. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with **get_dl_classifier_param**. Here we list the default values with which the classifier has been trained:
  - 'image_width': 224
  - 'image_height': 224
  - 'image_num_channels': 3
  - 'image_range_min': -127
  - 'image_range_max': 128

  This network does not contain any fully connected layer. The network architecture allows changes concerning the image dimensions, but requires a minimum 'image_width' and 'image_height' of 15 pixels.

- **'pretrained_dl_classifier_enhanced.hdl'**: This neural network has more hidden layers than **'pretrained_dl_classifier_compact.hdl'** and is therefore assumed to be better suited for more complex classification tasks. But this comes at the cost of being more time and memory demanding. As a result, e.g., in comparison to the above compact network, the batch size has to be decreased network during the training, see **set_dl_classifier_param**.

HALCON 20.05.0.0
This classifier expects the images to be of the type 'real'. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with get_dl_classifier_param. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127
'image_range_max': 128

The network architecture allows changes concerning the image dimensions, but requires a minimum 'image_width' and 'image_height' of 47 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Changing the image size will reinitialize the weights of the fully connected layers and therefore makes a retraining necessary.

'pretrained_dl_classifier_resnet50.hdl': As the neural network 'pretrained_dl_classifier_enhanced.hdl', this classifier is suited for more complex tasks. But its structure differs, bringing the advantage of making the training more stable and being internally more robust.

This classifier expects the images to be of the type 'real'. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with get_dl_classifier_param. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127
'image_range_max': 128

The network architecture allows changes concerning the image dimensions, but a minimum 'image_width' and 'image_height' of 32 pixels is recommended. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Despite the fully connected layer a change of the image size does not lead to a reinitialization of the weights.

The values listed above are the default image dimensions and gray value range for the networks and these are the values with which the classifiers have been trained. The network architectures allow different image sizes which can be set with set_dl_classifier_param. For networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained are likely to show a reduced classification accuracy.

The actually configured dimensions can be queried by get_dl_classifier_param. Every image that is fed into a network must be present according to the required dimensions. To adjust images accordingly, the procedure preprocess_dl_classifier_images is available.

Typically it is easier, faster and better to retrain a pretrained classifier for a given classification problem. A pretrained classifier has already learned good general purpose features. To retrain the network for a custom problem, the new 'classes' of the classifier have to be set with set_dl_classifier_param.

The neural network is loaded from the file FileName. This file is hereby searched in the directory ($HALCON-ROOT/dl/) as well as in the currently used directory.

Please note that the runtime specific parameter 'gpu' of the classifier is not read from file. Instead it is initialized with its default value (see set_dl_classifier_param).

The default HALCON file extension for deep learning classifiers is '.hdl'.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
### DL CLASSIFICATION

#### serialize_dl_classifier

Serialize a deep-learning-based classifier.

**serialize_dl_classifier** is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **serialize_dl_model**.

 serialize_dl_classifier serializes a deep-learning-based classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The classifier is defined by the handle DLClassifierHandle. The serialized classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialze_dl_classifier.

The operator acts the same as write_dl_classifier except that the output is a serialized item instead of a file. For a detailed description please refer to the documentation of write_dl_classifier.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

**Parameters**

- **DLClassifierHandle** (input_control)  
  Handle of the deep learning classifier.

- **SerializedItemHandle** (output_control)  
  Handle of the serialized item.

**Result**

If the parameters are valid, the operator serialize_dl_classifier returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

HALCON 20.05.0.0
Set the parameters of a deep-learning-based classifier.

**set_dl_classifier_param** is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **set_dl_model_param** instead.

**set_dl_classifier_param** sets the parameters and hyperparameters `GenParamName` of the neural network `DLClassifierHandle` to the values `GenParamValue`. The pretrained classifiers are trained for their default image dimensions, see **read_dl_classifier**.

The network architectures allow different image dimensions. But for networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained, are likely to show a reduced classification accuracy.

`GenParamName` can attain the following values:

- **`batch_size`**: Number of images (and corresponding labels) in a batch that is transferred to device memory. The batch of images which are processed simultaneously in a single training iteration contains a number of images which is equal to `batch_size` times `batch_size_multiplier`. Please refer to **train_dl_classifier_batch** for further details. The parameter `batch_size` is stored in the pretrained classifier. Per default, the `batch_size` is set such that a training of the pretrained classifier with up to 100 classes can be easily performed on a device with 8 gigabyte of memory. For the pretrained classifiers, the default values are hence given as follows:

<table>
<thead>
<tr>
<th>pretrained classifier</th>
<th>default value of <code>batch_size</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pretrained_dl_classifier_compact.hdl</code></td>
<td>160</td>
</tr>
<tr>
<td><code>pretrained_dl_classifier_enhanced.hdl</code></td>
<td>96</td>
</tr>
<tr>
<td><code>pretrained_dl_classifier_resnet50.hdl</code></td>
<td>23</td>
</tr>
</tbody>
</table>

For inference, the `batch_size` can be generally set independently from the number of input images. See **apply_dl_classifier** for details on how to set this parameter for greater efficiency.

- **`batch_size_multiplier`**: Multiplier for `batch_size` to enable training with larger numbers of images in one step which would otherwise not be possible due to GPU memory limitations. For detailed information see **train_dl_classifier_batch**. This model parameter does not have any impact during evaluation and inference. For the pretrained classifiers, the default value of `batch_size_multiplier` is set to 1.

- **`classes`**: Tuple of labels corresponding to the classes of objects which are to be recognized. The order of the class names remains unchanged after the setting.

- **`gpu`**: Identifier of the GPU where the training and inference operators (**train_dl_classifier_batch** and **apply_dl_classifier**) are executed. Per default, the first available GPU is used. **get_system** with `cuda_devices` can be used to retrieve a list of available GPUs. Pass the index in this list to `gpu`.

- **`image_width`**: Width of the images the network will process. The default value is given by the network, see **read_dl_classifier**.
'image_height': Height of the images the network will process. The default value is given by the network, see read_dl_classifier.

'image_num_channels': Number of channels of the images the network will process. Possible are one channel (gray value image), or three channels (three-channel image). The default value is given by the network, see read_dl_classifier. Changing to a single channel image modifies the network configuration. This process removes the color information contained in certain layers and is not invertible.

'image_dimensions': Tuple containing the image dimensions 'image_width', 'image_height', and number of channels 'image_num_channels'. The default values are given by the network, see read_dl_classifier. Concerning the number of channels, the values one (gray value image), or three (three-channel image) are possible. Changing to a single channel image modifies the network configuration. This process removes the color information contained in certain layers and is not invertible.

'learning_rate': Initial value of the factor determining the gradient influence during training. Please refer to train_dl_classifier_batch for further details. The default value depends on the classifier.

'momentum': When updating the arguments of the loss function, the hyperparameter 'momentum' specifies to which extent previous updating vectors will be added to the current updating vector. Please refer to train_dl_classifier_batch for further details. Per default, the 'momentum' is set to 0.9.

'runtime': Defines the device on which the operators will be executed. Per default, the 'runtime' is set to 'gpu'.

'cpu': The operator apply_dl_classifier will be executed on the CPU, whereas the operator train_dl_classifier_batch is not executable. In case the GPU has been used before, CPU memory is initialized, and if necessary values stored on the GPU memory are moved to the CPU memory. On Intel or AMD architectures the 'cpu' runtime uses OpenMP for the parallelization of apply_dl_classifier, where per default, all threads available to the OpenMP runtime are used. You may use the set_system parameter 'tsp_thread_num' to specify the number of threads. On Arm architectures the 'cpu' runtime uses a global thread pool. You may specify the number of threads with the set_system parameter 'thread_num'. You cannot specify a thread specific number of threads on Arm architectures.

'gpu': The GPU memory is initialized and the corresponding handle created. The operators apply_dl_classifier and train_dl_classifier_batch will be executed on the GPU. For the specific requirements please refer to the HALCON “Installation Guide”.

'runtime_init': If called with 'immediately', the GPU memory is initialized and the corresponding handle created. Otherwise this is done on demand, which may result in significantly larger execution times for the first call of apply_dl_classifier or train_dl_classifier_batch. If 'gpu' or 'batch_size' is changed with subsequent calls of set_dl_classifier_param, the GPU memory is reinitialized. Note, this parameter has no effect if running on CPUs, thus if 'runtime' is set to 'cpu'.

'weight_prior': Regularization parameter $\alpha \geq 0.0$ used for $l_2$ regularization of the loss function. Regularization is helpful in the presence of overfitting during the classifier training. If the hyperparameter 'weight_prior' is non-zero, the regularization term given below is added to the loss function (see also train_dl_classifier_batch)

$$E_\alpha(w) = \frac{\alpha}{2} \sum_{k=0}^{K-1} |w_k|^2$$

Here the index $k$ runs over all weights of the network, except for the biases which are not regularized. The regularization term $E_\alpha(w)$ generally penalizes large weights, thus pushing the weights towards zero, which effectively reduces the complexity of the model. Simply put: Regularization favors simpler models that are less likely to learn noise in the data and generalize better. In case the classifier overfits the data, it is strongly recommended to try different values for the parameter 'weight_prior' to improve the generalization properties of the neural network. Choosing its value is a trade-off between the models ability to generalize, overfitting, and underfitting. If $\alpha$ is too small, the model might overfit, if its too large the model might loose its ability to fit the data, because all weights are effectively zero. For finding an ideal value for $\alpha$, we recommend a cross-validation, i.e. to perform the training for a range of values and choose the value that results in the best validation error. For typical applications, we recommend testing the values for 'weight_prior' on a logarithmic scale between 1.0, ..., 0.0001. If the training takes a very long time, one might consider performing the hyperparameter optimization on a reduced amount of data. The default value depends on the classifier.
For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Attention

To successfully set ‘gpu’ parameters, cuDNN and cuBLAS are required, i.e., to set the parameter GenParamName ‘runtime’ to ‘gpu’ or to set the GenParamName ‘gpu’. For further details, please refer to the “Installation Guide”, paragraph “Requirements for Deep Learning”.

Parameters

- **DLClassifierHandle** (input_control)                 dl_classifier ~ handle
  Handle of the deep-learning-based classifier.
- **GenParamName** (input_control)                     attribute.name(-array) ~ string
  Name of the generic parameter.
  **Default value:** ‘classes’
- **GenParamValue** (input_control)                  attribute.value(-array) ~ string / real / integer
  Value of the generic parameter.
  **Default value:** [‘class_1’, ‘class_2’, ‘class_3’]
  **Suggested values:** GenParamValue ∈ {1, 2, 3, 50, 0.001, ‘cpu’, ‘gpu’, ‘immediately’}

Result

If the parameters are valid, the operator set_dl_classifier_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

Module

Deep Learning Inference

```cpp
train_dl_classifier_batch ( BatchImages : : DLClassifierHandle,
                          BatchLabels : : DLClassifierTrainResultHandle )
```

Perform a training step of a deep-learning-based classifier on a batch of images.

**train_dl_classifier_batch** is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **train_dl_model_batch**.

**train_dl_classifier_batch** performs a training step of the deep-learning-based classifier contained in **DLClassifierHandle**. The classifier handle **DLClassifierHandle** has to be read previously using **read_dl_classifier**. In order to apply training steps, classes have to be specified using **set_dl_classifier_param**. Other hyperparameters such as the learning rate and the momentum are also important for a successful training. They are set using **set_dl_classifier_param**.

The training step is done on basis of a single batch of images from the training dataset, thus the images **BatchImages** with labels **BatchLabels**. The number of images within the batch needs to be a multiple
of the ‘batch_size’ where the parameter ‘batch_size’ is limited by the amount of available GPU memory. In order to process more images in one training step, the classifier parameter ‘batch_size_multiplier’ can be set to a value greater than 1. The number of images being passed to the training operator needs to be equal to ‘batch_size’ times ‘batch_size_multiplier’. Note that a training step calculated for a batch and a ‘batch_size_multiplier’ greater 1 is an approximation of a training step calculated for the same batch but with a ‘batch_size_multiplier’ equal to 1 and an accordingly greater ‘batch_size’. As an example, the loss calculated with a ‘batch_size_multiplier’ of 4 and a ‘batch_size_multiplier’ of 2 is usually not equal to the loss calculated with a ‘batch_size’ of 8 and a ‘batch_size_multiplier’ of 1, although the same number of images is used for training in both cases. However, the approximation generally delivers comparably good results, so it can be utilized if you wish to train with a larger number of images than your GPU allows. In some rare cases the approximation with a ‘batch_size’ of 1 and an accordingly large ‘batch_size_multiplier’ does not show the expected performance which for example can happen when the pretrained network ‘pretrained_dl_classifier_resnet50.hdl’ is used. Setting the ‘batch_size’ to a value greater than 1 can help to solve this issue.

Note that the images in BatchImages must fulfill certain conditions regarding, for example, the image size and gray value range, depending on the chosen network. Please have a look at read_dl_classifier and set_dl_classifier_param for more information. The labels in BatchLabels can be handed over as an array of strings, or as an array of indices corresponding to the position of the label within the array of classes (counting from 0) set before via ‘classes’ with set_dl_classifier_param. Information about the results of the training step as the value of the loss are stored in DLClassifierTrainResultHandle and can be accessed using get_dl_classifier_train_result.

Note that an epoch generally consists of a large number of batches and that a successful training involves many epochs. Therefore train_dl_classifier_batch has to be applied several times with different batches. For a more detailed explanation, we refer to Legacy / DL Classification.

During training, a nonlinear optimization algorithm minimizes the value of the loss function. The later one is determined based on the prediction of the neural network on the current batch of images. The algorithm used for optimization is stochastic gradient descent (SGD). It updates the layers’ weights of the previous iteration \( w_t \) to the new values \( w_{t+1} \) at iteration \( t + 1 \) as follows:

\[
\begin{align*}
    v_{t+1} &= \mu v_t - \lambda \nabla_w L(f(x, w^t)) \\
    w_{t+1} &= w^t + v_{t+1}.
\end{align*}
\]

Here, \( \lambda \) is the learning rate, \( \mu \) for the momentum, and \( f(x, w) \) for the classification result of the deep learning-based classifier which depends on the deep network weights \( w \) and the input batch \( x \). The variable \( v_t \) is used to involve the influence of the momentum \( \mu \). The loss function used here is the Multinomial Logistic Loss in combination with a quadratic regularization term \( E_\alpha(w) \),

\[
L(f(x, w)) = -\frac{1}{N} \sum_{n=0}^{N-1} (y_n, \log(f(x_n, w))) + E_\alpha(w), \quad E_\alpha(w) = \frac{\alpha}{2} \sum_{k=0}^{K-1} |w_k|^2.
\]

Here, \( y_n \) is a one-hot encoded target vector that encodes the label of the \( n \)-th image \( x_n \) of the batch \( x \) containing \( N \)-many images, and \( \log(f(x_n, w)) \) shall be understood to be a vector such that \( \log \) is applied on each component of \( f(x_n, w) \). The regularization term \( E_\alpha(w) \) is a weighted \( l^2 \)-norm involving all \( K \) weights except for biases. Its influence can be controlled through \( \alpha \). In the above formula, \( \alpha \) denotes the hyperparameter ‘weight_prior’ that can be set with set_dl_classifier_param. In order to gain more insight, you can retrieve the current value of the total loss function as well as individual contributions using get_dl_classifier_train_result.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

---

Attention

The operator train_dl_classifier_batch internally calls functions that might not be deterministic. Therefore, results from multiple calls of train_dl_classifier_batch can slightly differ, although the same input values have been used.

To run this operator, cuDNN and cuBLAS are required. For further details, please refer to the “Installation Guide”, paragraph “Requirements for Deep Learning.”
Parameters

- **BatchImages** (input_object) \( \ldots \) (multichannel-)image(-array) \( \leadsto \) object : real
  Images comprising the batch.

- **DLClassifierHandle** (input_control) \( \ldots \) dl_classifier \( \leadsto \) handle
  Handle of the deep-learning-based classifier.

- **BatchLabels** (input_control) \( \ldots \) string-array \( \leadsto \) string / integer
  Corresponding labels for each of the images.
  Default value: \([\ ]\)
  List of values: BatchLabels \( \in \{[\ ]\} \)

- **DLClassifierTrainResultHandle** (output_control) \( \ldots \) dl_classifier_train_result \( \leadsto \) handle
  Handle of the training results from the deep-learning-based classifier.

Result

If the parameters are valid, the operator `train_dl_classifier_batch` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

- `read_dl_classifier`, `set_dl_classifier_param`, `get_dl_classifier_param`

Possible Successors

- `get_dl_classifier_train_result`, `apply_dl_classifier`, `clear_dl_classifier_train_result`, `clear_dl_classifier`

Alternatives

- `train_dl_model_batch`, `train_class_mlp`, `train_class_svm`

See also

- `apply_dl_classifier`

Module

Deep Learning Training

```plaintext
write_dl_classifier ( : : DLClassifierHandle, FileName : )
```

Write a deep-learning-based classifier in a file.

`write_dl_classifier` is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator `write_dl_model` instead.

`write_dl_classifier` writes the deep-learning-based classifier `DLClassifierHandle` to the file given by `FileName`.

`write_dl_classifier` is typically called after the classifier has been trained with `train_dl_classifier_batch`. The classifier can be read with `read_dl_classifier`.

Please note that the runtime specific parameter ‘gpu’ of the classifier is not written.

The default HALCON file extension for deep learning classifiers is `.hdl`.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
### Parameters

- **DLClassifierHandle** (input_control) ............................ **dl_classifier**  \( \rightarrow \) **handle**
  Handle of the deep-learning-based classifier.
- **FileName** (input_control) ................................. **filename.write**  \( \rightarrow \) **string**
  File name.
  **File extension**: `.hdl`

---

### Result

If the parameters are valid, the operator **write_dl_classifier** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

### Possible Predecessors

- **read_dl_classifier**, **train_dl_classifier_batch**, **set_dl_classifier_param**

### Alternatives

- **write_dl_model**

---

### Module

**Deep Learning Inference**

---

### 17.5 Develop

```python
dev_map_par (: : : )
```

*Open the dialog to specify the visualization parameters.*

**dev_map_par** is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_open_tool** with **ToolType** set to 'visualization_parameters_dialog' instead.

**dev_map_par** opens the Visualization Parameter dialog. This can also be achieved interactively via the menu **Visualization** \( \xrightarrow{\text{Set Parameters...}} \) or the appropriate tool bar button. The dialog is used to configure the visualization parameters that are used to display iconic objects.

---

### Attention

This operator is not supported for code export.

---

### Example

```python
read_image (Image, 'fabrik')
threshold (Image, Region, 128, 255)
dev_map_par ()
```

---

### Result

**dev_map_par** returns always 2 (H_MSG_TRUE).

---

### Possible Successors

- **dev_unmap_par**

---

### Module

**Foundation**

---

```python
dev_map_prog (: : : )
```

*Make the main window of HDevelop visible.*
dev_map_prog is obsolete and is only provided for reasons of backward compatibility. New applications should use dev_open_tool with ToolType set to 'program_window' instead.

dev_map_prog is used to re-show (map) the main window of HDevelop after it has been hidden (unmapped) by dev_unmap_prog.

```cpp
Attention
```

This operator is not supported for code export.

Depending on the operating system or the window manager the execution of dev_map_prog will result only in a visible icon of the window. In this case it has to be opened by the user with mouse interaction.

```cpp
Result
dev_map_prog always returns 2 (H_MSG_TRUE).
```

Possible Predecessors:
- dev_unmap_prog

Possible Successors:
- dev_unmap_prog

See also:
- dev_map_par, dev_map_var

Module:
- Foundation

---

**dev_map_var** ( : : : )

Open the variable window of HDevelop.

dev_map_var is obsolete and is only provided for reasons of backward compatibility. New applications should use dev_open_tool with ToolType set to 'variable_window' instead.

dev_map_var is used to re-show (map) the variable window on the screen after it has been hidden (unmapped) by dev_unmap_var.

```cpp
Attention
```

This operator is not supported for code export.

```cpp
Result
dev_map_var always returns 2 (H_MSG_TRUE).
```

Possible Predecessors:
- dev_unmap_var

Possible Successors:
- dev_unmap_var

See also:
- dev_map_par, dev_map_prog

Module:
- Foundation

---

**dev_unmap_par** ( : : : )

Closes the dialog to specify the visualization parameters.

dev_unmap_par is obsolete and is only provided for reasons of backward compatibility. New applications should use dev_close_tool with ToolType set to 'visualization_parameters_dialog' instead.

dev_unmap_par closes the Visualization Parameter dialog. This can also be achieved interactively by pressing the Close button on the dialog's title bar. The dialog can be opened again by dev_map_par.

```cpp
Attention
```

This operator is not supported for code export.
### dev_unmap_par

Always returns 2 (H_MSG_TRUE).

#### Possible Successors

- dev_map_par

#### See also

- dev_map_par
- dev_map_prog
- dev_map_var

#### Module

Foundation

---

**dev_unmap_par**

Hide the main window.

dev_unmap_par is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_close_tool** with ToolType set to 'program_window' instead.

dev_unmap_par hides in MDI mode the main window and in SDI mode the program window so that it is no longer visible. It can be shown again by **dev_map_prog**.

Attention: after hiding the main window there is no opportunity to enter and execute the **dev_map_prog** operator. So take care that dev_unmap_par is only executed in continuous mode with a reachable **dev_map_prog** operator.

This operator is not supported for code export.

---

**dev_unmap_var**

Hides the variable window.

dev_unmap_var is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_close_tool** with ToolType set to 'variable_window' instead.

dev_unmap_var hides the variable window. This can also be achieved interactively by pressing the Close button on the window’s title bar. The window can be opened again by **dev_map_var** or interactively via the Window menu.

This operator is not supported for code export.
17.6 Filters

**gauss_image** (Image : ImageGauss : Size : )

Smooth an image using discrete Gaussian functions.

*gauss_image* is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator *gauss_filter* instead.

The operator *gauss_image* smoothes images using the discrete Gaussian. The smoothing effect increases with increasing filter size. The following filter sizes (*Size*) are supported (the sigma value of the gauss function is indicated in brackets):

<table>
<thead>
<tr>
<th>Size</th>
<th>Sigma Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>0.65</td>
</tr>
<tr>
<td>5</td>
<td>0.87</td>
</tr>
<tr>
<td>7</td>
<td>1.43</td>
</tr>
<tr>
<td>9</td>
<td>1.88</td>
</tr>
<tr>
<td>11</td>
<td>2.31</td>
</tr>
</tbody>
</table>

For border treatment the gray values of the images are reflected at the image borders.

The operator *binomial_filter* can be used as an alternative to *gauss_image*. *binomial_filter* is significantly faster than *gauss_image*. It should be noted that the mask size in *binomial_filter* does not lead to the same amount of smoothing as the mask size in *gauss_image*. Corresponding mask sizes can be determined based on the respective values of the Gaussian smoothing parameter sigma.

*gauss_image* can be executed on OpenCL devices for all supported image types. However, the OpenCL implementation can produce slightly different results from the scalar implementation.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

**Attention**

In order to be able to process *gauss_image* on an OpenCL device, *Image* must be at least 64 pixels in both width and height.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

**Parameters**

- **Image** (input_object) .......... (multichannel-)image(array) ~ object : byte / int2 / uint2 / int4 / real
  Image to be smoothed.
- **ImageGauss** (output_object) .......(multichannel-)image(array) ~ object : byte / int2 / uint2 / int4 / real
  Filtered image.
- **Size** (input_control) ............................................... integer ~ integer
  Required filter size.
  Default value: 5
  List of values: Size ∈ {3, 5, 7, 9, 11}

**Example**

```
gauss_image(Input,Gauss,7)
regiongrowing(Gauss,Segments,7,7,5,100)
```

**Complexity**

For each pixel: $O(Size \times 2)$.

**Result**

If the parameter values are correct the operator *gauss_image* returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator *set_system* ('no_object_result',<Result>). If necessary an exception is raised.

**Parallelization**

- Supports OpenCL compute devices.
17.6. FILTERS

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

| polar_trans_image ( ImageXY : ImagePolar : Row, Column, Width, Height : ) |

Transform an image to polar coordinates

polar_trans_image is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator polar_trans_image_ext instead.

polar_trans_image transforms an image in cartesian coordinates to an image in polar coordinates. The size of the resulting image is selected with Width and Height. Width determines the angular resolution, while Height determines the resolution of the radius. Row and Column determine the center of the polar coordinate system in the original image ImageXY. This point is mapped to the upper row of ImagePolar.

A point (x',y') in the result image corresponds to the point (x,y) in the original image in the following manner:

\[ x = y' \cos(2\pi(x'/\text{resultwidth})) + \text{Column} \]
\[ y = y' \sin(2\pi(x'/\text{resultwidth})) + \text{Row} \]

polar_trans_image can be executed on an OpenCL device if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- ImageXY (input_object) (multichannel-)image(array) \( \sim \) object : byte / int2 / uint2 / real
  Input image in cartesian coordinates.
- ImagePolar (output_object) (multichannel-)image(array) \( \sim \) object : byte / int2 / uint2 / real
  Result image in polar coordinates.
- Row (input_control) point.y \( \sim \) integer
  Row coordinate of the center of the coordinate system.
  Default value: 100
  Suggested values: Row \( \in\) \{0, 10, 100, 200\}
  Typical range of values: 0 \( \leq \) Row \( \leq \) 512
  Minimum increment: 1
  Recommended increment: 1
- Column (input_control) point.x \( \sim \) integer
  Column coordinate of the center of the coordinate system.
  Default value: 100
  Suggested values: Column \( \in\) \{0, 10, 100, 200\}
  Typical range of values: 0 \( \leq \) Column \( \leq \) 512
  Minimum increment: 1
  Recommended increment: 1
- Width (input_control) extent.x \( \sim \) integer
  Width of the result image.
  Default value: 314
  Suggested values: Width \( \in\) \{100, 200, 157, 314, 512\}
  Typical range of values: 2 \( \leq \) Width \( \leq \) 512
  Minimum increment: 1
  Recommended increment: 10
**Height** (input_control)  

Height of the result image.

**Default value:** 200

**Suggested values:** Height \( \in \{100, 128, 256, 512\} \)

**Typical range of values:** \( 2 \leq \text{Height} \leq 512 \)

Minimum increment: 1

Recommended increment: 10

---

Example

```plaintext
read_image(Image,'monkey')
dev_display (Image)
polar_trans_image(Image,PolarImage,100,100,314,200)
dev_display (PolarImage)
```

---

**Parallelization**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

---

**Module**

17.7 Graphics

**clear_rectangle** ( : : WindowHandle, Row1, Column1, Row2, Column2 : )

Delete a rectangle on the output window.

**clear_rectangle** is obsolete and is only provided for reasons of backward compatibility.

**clear_rectangle** deletes all entries in the rectangle which is defined through the upper left corner (Row1,Column1) and the lower right corner (Row2,Column2). Deletion means that the specified rectangle is set to the background color (see `open_window`).

If you want to delete more than one rectangle, you may pass several rectangles, i.e., the parameters Row1, Column1, Row2 and Column2 are tuples.

---

**Parameters**

- **WindowHandle** (input_control)  
  Window handle.

- **Row1** (input_control)  
  Line index of upper left corner.

  **Default value:** 10

  **Typical range of values:** \( 0 \leq \text{Row1} \leq 511 \) (lin)

  Minimum increment: 1

  Recommended increment: 1

- **Column1** (input_control)  
  Column index of upper left corner.

  **Default value:** 10

  **Typical range of values:** \( 0 \leq \text{Column1} \leq 511 \) (lin)

  Minimum increment: 1

  Recommended increment: 1
17.7. GRAPHICS

- **Row2** (input_control) \( \text{rectangle.corner.y(-array)} \) \( \sim \) integer
  - Row index of lower right corner.
  - Default value: 118
  - Typical range of values: \( 0 \leq \text{Row2} \leq 511 \) (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: Row2 > Row1

- **Column2** (input_control) \( \text{rectangle.corner.x(-array)} \) \( \sim \) integer
  - Column index of lower right corner.
  - Default value: 118
  - Typical range of values: \( 0 \leq \text{Column2} \leq 511 \) (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: Column2 \( \geq \) Column1

--- Example

* Erase a rectangle in the output window interactively:
draw_rectangle1(WindowHandle,L1,C1,L2,C2)

--- Result

If an output window exists and the specified parameters are correct clear_rectangle returns 2 (H_MSG_TRUE). If necessary an exception is raised.

--- Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Possible Predecessors

open_window, set_draw, set_color, set_colored, set_line_width, set_rgb, set_hsi, draw_rectangle1

--- Alternatives

clear_window, disp_rectangle1

--- See also

open_window

--- Module

Foundation

disp_distribution ( : : WindowHandle, Distribution, Row, Column, Scale : )

Displays a noise distribution.

disp_distribution is obsolete and is only provided for reasons of backward compatibility.

disp_distribution displays a distribution in the window. The parameters are the same as in set_paint (WindowHandle,’histogram’) or gen_region_histo. Noise distributions can be generated with operations like gauss_distribution or noise_distribution_mean.

--- Parameters

- **WindowHandle** (input_control) \( \text{window} \sim \text{handle} \)
  - Window handle.

- **Distribution** (input_control) \( \text{real-array} \sim \text{real} \)
  - Gray value distribution (513 values). 

HALCON 20.05.0.0
Row (input_control) ............................................................. point.y ~ integer
Row index of center.
Default value: 256
Suggested values: Row ∈ {0, 64, 128, 256}
Typical range of values: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

Column (input_control) ........................................................ point.x ~ integer
Column index of center.
Default value: 256
Suggested values: Column ∈ {0, 64, 128, 256}
Typical range of values: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

Scale (input_control) .......................................................... integer ~ integer
Size of display.
Default value: 1
Suggested values: Scale ∈ {1, 2, 3, 4, 5, 6}

Example

open_window(0,0,-1,-1,'root','visible','',WindowHandle)
set_draw(WindowHandle,'fill')
set_color(WindowHandle,'white')
read_image(Image,'monkey')
draw_region(Region,WindowHandle)
noise_distribution_mean(Region,Image,21,Distribution)
disp_distribution (WindowHandle,Distribution,100,100,3)

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
open_window, set_draw, set_color, set_colored, set_line_width, set_rgb, set_hsi,
noise_distribution_mean, gauss_distribution

See also
gen_region_histo, set_paint, gauss_distribution, noise_distribution_mean

Module

**disp_lut** ( : : WindowHandle, Row, Column, Scale : )

Graphical view of the look-up-table (lut).

disp_lut is obsolete and is only provided for reasons of backward compatibility.

disp_lut displays a graphical view of the look-up-table (lut) in the valid window. A look-up-table defines the transformation of image gray values to colors/gray levels on the screen. On most systems this can be modified. disp_lut creates a graphical view of the table assigned to the output window with the logical window number WindowHandle and displays it for every basic color (red, green, blue). Row and Column define the position of the centre of the graphic. Scale allows scaling of the graphic, whereas 1 means displaying all 256 values, 2 means displaying 128 values, 3 means displaying only 64 values, etc. Tables for monochrome-representations are displayed in the currently set color (see set_color, set_rgb, etc.). Tables for displaying “false colors” are viewed with red, green and blue for each color component.
Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Row** (input_control)  
  Row of centre of the graphic.  
  Default value: 128  
  Typical range of values: \(0 \leq \text{Row} \leq 511\)

- **Column** (input_control)  
  Column of centre of the graphic.  
  Default value: 128  
  Typical range of values: \(0 \leq \text{Column} \leq 511\)

- **Scale** (input_control)  
  Scaling of the graphic.  
  Default value: 1  
  List of values: \(\text{Scale} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}\)  
  Typical range of values: \(0 \leq \text{Scale} \leq 20\)

Example

```python
set_lut(WindowHandle, 'color1')
disp_lut(WindowHandle, 256, 256, 1)
get_mbutton(WindowHandle, _, _, _)
set_lut(WindowHandle, 'sqrt')
disp_lut(WindowHandle, 128, 128, 2)
```

Result

disp_lut returns 2 (H_MSG_TRUE) if the hardware supports a look-up-table, the window is valid and the parameters are correct. Otherwise an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- **set_lut**

Module

- **Foundation**

```python
get_comprise ( : : WindowHandle : : Mode )
```

Get the output treatment of an image matrix.

**get_comprise** is obsolete and is only provided for reasons of backward compatibility.

get_comprise returns the output mode of gray values in the window **WindowHandle** that is used by **disp_image** and **disp_color**. The output mode defines whether only the gray values of objects are displayed or the whole image is displayed. The query is used for temporary mode settings, i.e., the current mode is queried, then overwritten with (**set_comprise**) and finally reset.
### Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Mode** (output_control)  
  Display mode for images.

---

### Result

`get_comprise` returns `2 (H_MSG_TRUE)` if the window is valid. Otherwise an exception is raised.

---

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

### Possible Successors

### Module

**Foundation**

```cpp
get_fix ( : : WindowHandle : Mode )
```

Get mode of fixing of current look-up-table (lut).

### get_fix is obsolete and is only provided for reasons of backward compatibility.

Use `get_fix` to get mode of fixing of current look-up-table (look-up-table of valid window) set before by `set_fix`.

---

### Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Mode** (output_control)  
  Current Mode of fixing.

---

### Result

`get_fix` returns `2 (H_MSG_TRUE)` if the window is valid. Otherwise an exception is raised.

---

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

  See also

- `set_fix`  
  See also

---

### Module

**Foundation**

```cpp
get_fixed_lut ( : : WindowHandle : Mode )
```

Get fixing of “look-up-table” (lut) for “real color images”

get_fixed_lut is obsolete and is only provided for reasons of backward compatibility.

Get fixing of “look-up-table” (lut) for “real color images”

- Parameters

  - WindowHandle (input_control) : window ～ handle
    Window handle.

  - Mode (output_control) : string ～ string
    Mode of fixing.

- Parallelization

  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

- Possible Successors

  - set_fixed_lut

Foundation

get_insert ( : : WindowHandle : Mode )

Get the current display mode.

get_insert is obsolete and is only provided for reasons of backward compatibility.

get_insert returns the display mode of the output window. It is used by operators like disp_region, disp_line, disp_rectangle1, etc. The mode is set with set_insert. Possible values for Mode can be queried with the operator query_insert.

- Parameters

  - WindowHandle (input_control) : window ～ handle
    Window handle.

  - Mode (output_control) : string ～ string
    Display mode.

- Result

  - get_insert returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

- Parallelization

  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

- Possible Predecessors

  - query_insert

- Possible Successors

  - set_insert, disp_image

- See also

  - set_insert, query_insert, disp_region, disp_line

Foundation

get_line_approx ( : : WindowHandle : Approximation )

Get the current approximation error for contour display.
get_line_approx is obsolete and is only provided for reasons of backward compatibility.

get_line_approx returns a parameter that controls the approximation error for region contour display in the window. It is used by the operator disp_region. Approximation controls the polygon approximation for contour display (0 ⇔ no approximation). Approximation is only important for displaying the contour of objects, especially if a line style was set with set_line_style.

Parameters

- WindowHandle (input_control) .................. window ↦ handle
  Window handle.
- Approximation (output_control) .................. string ↦ integer
  Current approximation error for contour display.

Result

get_line_approx returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_line_approx, set_line_style, disp_region

See also

get_region_polygon, set_line_approx, set_line_style, disp_region

Module

Foundation

get_lut_style ( : : WindowHandle : Hue, Saturation, Intensity )

Get modification parameters of look-up-table (lut).

get_lut_style is obsolete and is only provided for reasons of backward compatibility.

get_lut_style returns the values that were set with set_lut_style. Default is:

- Hue: 0.0
- Saturation: 1.0
- Intensity: 1.0

Parameters

- WindowHandle (input_control) .................. window ↦ handle
  Window handle.
- Hue (output_control) .......................... real ↦ real
  Modification of color value.
- Saturation (output_control) ................ real ↦ real
  Modification of saturation.
- Intensity (output_control) ................ real ↦ real
  Modification of intensity.

Result

get_lut_style returns 2 (H_MSG_TRUE) if the window is valid and the parameter is correct. Otherwise an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

get_pixel( : WindowHandle : Pixel )

Get the current color lookup table index.

get_pixel is obsolete and is only provided for reasons of backward compatibility.

get_pixel returns the internal coding of the output gray value or color, respectively, for the window. If the output mode is set to color(s) or gray value(s) (see set_color or set_gray), then the color- or gray values are transformed for internal use. The internal code is then used for (physical) screen display. The transformation depends on the mapping characteristics and the condition of the output device and can be different in different program runs. Don’t confuse the term “pixel” with the term “pixel” in image processing (the other operator is get_grayval). Here a pixel is meant to be the color lookup table index.

With get_pixel it is possible to save the output mode without knowing whether colors or gray values are used. Pixel is set with the operator set_pixel.

Parameters

> WindowHandle (input_control) window
  Window handle.
> Pixel (output_control) integer-array
  Index of the current color look-up table.

Result

get_part_style returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

get_tshape( : WindowHandle : TextCursor )

Get the shape of the text cursor.

get_tshape is obsolete and is only provided for reasons of backward compatibility.

get_tshape queries the shape of the text cursor for the output window. A new cursor shape is set by the operator set_tshape.
A text cursor marks the current position for text output (which can also be invisible). It is different from the mouse cursor (although both will be called "cursor" if the context makes misconceptions impossible). The available shapes for the text cursor can be queried with \texttt{query\_tshape}.

\begin{verbatim}
Parameters

\textbf{WindowHandle} (input\_control) \hspace{0.5em} \textbf{handle}
Window handle.

\textbf{TextCursor} (output\_control) \hspace{0.5em} \textbf{string}
Name of the current text cursor.

Result
get\_tshape returns 2 (H\_MSG\_TRUE) if the window is valid. Otherwise an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
open\_window, set\_font

Possible Successors
set\_tshape, set\_tposition, write\_string, read\_string, read\_char

See also
set\_tshape, query\_tshape, write\_string, read\_string

Module
Foundation
\end{verbatim}

\texttt{gnuplot\_close} ( : : GnuplotFileID : )

Close all open gnuplot files or terminate an active gnuplot sub-process.

\texttt{gnuplot\_close} is obsolete and is only provided for reasons of backward compatibility.

\texttt{gnuplot\_close} closes all gnuplot files opened by \texttt{gnuplot\_open\_file} or terminates the gnuplot sub-process created with \texttt{gnuplot\_open\_pipe}. In the latter case, all temporary files used to display images and control values are deleted. This means that \texttt{gnuplot\_close} must be called after such a plot sequence. \texttt{GnuplotFileID} is the identifier of the corresponding gnuplot output stream.

\begin{verbatim}
Parameters

\textbf{GnuplotFileID} (input\_control) \hspace{0.5em} \textbf{handle}
Identifier for the gnuplot output stream.

Result
\texttt{gnuplot\_close} returns 2 (H\_MSG\_TRUE) if \texttt{GnuplotFileID} is a valid gnuplot output stream. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
\texttt{gnuplot\_open\_pipe, gnuplot\_open\_file, gnuplot\_plot\_image}

See also
\texttt{gnuplot\_open\_pipe, gnuplot\_open\_file, gnuplot\_plot\_image}

Module
Foundation
\end{verbatim}
Open a gnuplot file for visualization of images and control values.

**gnuplot_open_file** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_open_file** allows the output of images and control values in a format which can be later processed by gnuplot. The parameter **FileName** determines the base-name of the files to be created by calls to **gnuplot_plot_image**. **gnuplot_open_file** generates a gnuplot control file with the name `<FileName>.gp`, in which the respective plot commands are written. Each image plotted by **gnuplot_plot_image** (or control values plotted by **gnuplot_plot_ctrl**) creates a data file with the name `<FileName>.dat.<Number>`, where Number is the number of the plot in the current sequence. The generated control file can later be edited to create the desired effect. After the last plot **gnuplot_close** has to be called in order to close all open files. The corresponding identifier for the gnuplot output stream is returned in **GnuplotFileID**.

**Parameters**

▷ **FileName** (input_control) ..........................  filename.write ~> string
   Base name for control and data files.
   File extension: .gp

▷ **GnuplotFileID** (output_control) .......................... gnuplot ~> handle
   Identifier for the gnuplot output stream.

**Result**

**gnuplot_open_file** returns the value 2 (H_MSG_TRUE) if the control file could be opened. Otherwise, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Successors**

**gnuplot_plot_image, gnuplot_close**

**Alternatives**

**gnuplot_open_pipe**

**See also**

**gnuplot_open_pipe, gnuplot_close, gnuplot_plot_image**

**Module**

**Foundation**

Open a pipe to a gnuplot process for visualization of images and control values.

**gnuplot_open_pipe** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_open_pipe** opens a pipe to a gnuplot sub-process with which subsequently images can be visualized as 3D-plots (**gnuplot_plot_image**) or control values can be visualized as 2D-plots (**gnuplot_plot_ctrl**). The sub-process must be terminated after displaying the last plot by calling **gnuplot_close**. The corresponding identifier for the gnuplot output stream is returned in **GnuplotFileID**.

**Attention**

**gnuplot_open_pipe** is only implemented for Unix-like systems because gnuplot for Windows (**wgnuplot**) cannot be controlled by an external process.
CHAPTER 17 LEGACY

Parameters

- **GnuplotFileID** (output_control) ................................. gnuplot ~ handle
  Identifier for the gnuplot output stream.

Result

- gnuplot_open_pipe returns the value 2 (H_MSG_TRUE) if the sub-process could be created. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

- gnuplot_plot_image, gnuplot_plot_ctrl, gnuplot_close

Alternatives

- gnuplot_open_file

Module

Foundation

**gnuplot_plot_ctrl** ( : : GnuplotFileID, Values : )

Plot control values using gnuplot.

**gnuplot_plot_ctrl** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_plot_ctrl** displays a tuple of control values using gnuplot. If there is an active gnuplot sub-process (started with **gnuplot_open_pipe**), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by **GnuplotFileID**.

Parameters

- **GnuplotFileID** (input_control) ................................. gnuplot ~ handle
  Identifier for the gnuplot output stream.
- **Values** (input_control) ................................. number-array ~ real / integer
  Control values to be plotted (y-values).

Result

- **gnuplot_plot_ctrl** returns the value if **GnuplotFileID** is a valid gnuplot output stream, if the data file for the current plot could be opened, and if only integer or floating point values were passed. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation
**gnuplot_plot_funct_1d** ( : : GnuplotFileID, Function : )

Plot a function using gnuplot.

**gnuplot_plot_funct_1d** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_plot_ctrl** displays a function of control values using gnuplot. If there is an active gnuplot subprocess (started with **gnuplot_open_pipe**), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by **GnuplotFileID**.

**Parameters**

- **GnuplotFileID** (input_control) : handle Identifier for the gnuplot output stream.
- **Function** (input_control) : function_1d Function to be plotted.

**Result**

**gnuplot_plot_ctrl** returns 2 (H_MSG_TRUE) if **GnuplotFileID** is a valid gnuplot output stream, and if the data file for the current plot could be opened. Otherwise, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- **gnuplot_open_pipe, gnuplot_open_file**

**Possible Successors**

- **gnuplot_close**

**Alternatives**

- **See also**

**gnuplot_open_pipe, gnuplot_open_file, gnuplot_close**

**Module**

**gnuplot_plot_image** ( Image : : GnuplotFileID, SamplesX, SamplesY, ViewRotX, ViewRotZ, Hidden3D : )

Visualize images using gnuplot.

**gnuplot_plot_image** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_plot_image** displays an image as a 3D-plot using gnuplot. If there is an active gnuplot sub-process (started with **gnuplot_open_pipe**), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by **GnuplotFileID**. The parameters **SamplesX** and **SamplesY** determine the number of data points in the x- and y-direction, respectively, which gnuplot should use to display the image. They are the equivalent of the gnuplot variables samples and isosamples. The parameters **ViewRotX** and **ViewRotZ** determine the rotation of the plot with respect to the viewer. **ViewRotX** is the rotation of the coordinate system about the x-axis, while **ViewRotZ** is the rotation of the plot about the z-axis. These two parameters correspond directly to the first two parameters of the ’set view’ command in gnuplot. The parameter **Hidden3D** determines whether hidden surfaces should be removed. This is equivalent to the ’set hidden3d’ command in gnuplot. If a single image is passed to the operator, it is displayed in a separate plot. If multiple images are passed, they are displayed in the same plot.
Parameters

☐ **Image** (input_object) ...... singlechannelimage ~> object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real

Image to be plotted.

☐ **GnuplotFileID** (input_control) .................................................. gnuplot ~> handle

Identifier for the gnuplot output stream.

☐ **SamplesX** (input_control) ........................................................ integer ~> integer

Number of samples in the x-direction.

Default value: 64
Typical range of values: \( 2 \leq \text{SamplesX} \leq 10000 \)
Restriction: \( \text{SamplesX} \geq 2 \)

☐ **SamplesY** (input_control) ........................................................ integer ~> integer

Number of samples in the y-direction.

Default value: 64
Typical range of values: \( 2 \leq \text{SamplesY} \leq 10000 \)
Restriction: \( \text{SamplesY} \geq 2 \)

☐ **ViewRotX** (input_control) ...................................................... number ~> real / integer

Rotation of the plot about the x-axis.

Default value: 60
Typical range of values: \( 0 \leq \text{ViewRotX} \leq 180 \)
Minimum increment: 0.01
Recommended increment: 10
Restriction: \( 0 \leq \text{ViewRotX} \leq 180 \)

☐ **ViewRotZ** (input_control) ...................................................... number ~> real / integer

Rotation of the plot about the z-axis.

Default value: 30
Typical range of values: \( 0 \leq \text{ViewRotZ} \leq 360 \)
Minimum increment: 0.01
Recommended increment: 10
Restriction: \( 0 \leq \text{ViewRotZ} \leq 360 \)

☐ **Hidden3D** (input_control) ...................................................... string ~> string

Plot the image with hidden surfaces removed.

Default value: "hidden3d"

List of values: Hidden3D ∈ \{'hidden3d', 'nohidden3d'\}

Result

**gnuplot_plot_image** returns the value if **GnuplotFileID** is a valid gnuplot output stream, and if the data file for the current plot could be opened. Otherwise, an exception is raised.

Module

Foundation
move_rectangle ( : : WindowHandle, Row1, Column1, Row2, Column2, DestRow, DestColumn : )

Copy inside an output window.

move_rectangle is obsolete and is only provided for reasons of backward compatibility.

move_rectangle copies all entries in the rectangle \((Row1, Column1)\), \((Row2, Column2)\) of the output window to a new position inside the same window. This position is determined by the upper left corner \((DestRow, DestColumn)\). Regions of the window, which are “uncovered” through moving the rectangle, are set to the color of the background.

If you want to move several rectangles at once, you may pass parameters in form of tuples.

--- Parameters ---

- **WindowHandle** (input_control) window handle.  
- **Row1** (input_control) \(rectangle\).origin.y\(-array\) integer  
  - Row index of upper left corner of the source rectangle.  
  - Default value: 0  
  - Typical range of values: \(0 \leq Row1 \leq 511 \text{ (lin)}\)  
  - Minimum increment: 1  
  - Recommended increment: 1  
- **Column1** (input_control) \(rectangle\).origin.x\(-array\) integer  
  - Column index of upper left corner of the source rectangle.  
  - Default value: 0  
  - Typical range of values: \(0 \leq Column1 \leq 511 \text{ (lin)}\)  
  - Minimum increment: 1  
  - Recommended increment: 1  
- **Row2** (input_control) \(rectangle\).corner.y\(-array\) integer  
  - Row index of lower right corner of the source rectangle.  
  - Default value: 64  
  - Typical range of values: \(0 \leq Row2 \leq 511 \text{ (lin)}\)  
  - Minimum increment: 1  
  - Recommended increment: 1  
- **Column2** (input_control) \(rectangle\).corner.x\(-array\) integer  
  - Column index of lower right corner of the source rectangle.  
  - Default value: 64  
  - Typical range of values: \(0 \leq Column2 \leq 511 \text{ (lin)}\)  
  - Minimum increment: 1  
  - Recommended increment: 1  
- **DestRow** (input_control) point.y\(-array\) integer  
  - Row index of upper left corner of the target position.  
  - Default value: 64  
  - Typical range of values: \(0 \leq DestRow \leq 511 \text{ (lin)}\)  
  - Minimum increment: 1  
  - Recommended increment: 1  
- **DestColumn** (input_control) point.x\(-array\) integer  
  - Column index of upper left corner of the target position.  
  - Default value: 64  
  - Typical range of values: \(0 \leq DestColumn \leq 511 \text{ (lin)}\)  
  - Minimum increment: 1  
  - Recommended increment: 1

--- Example ---

* "Interactive" copy of a rectangle in the same window  
draw_rectangle1 (WindowHandle, L1, C1, L2, C2)  
get_mbutton (WindowHandle, LN, CN, Button)  
move_rectangle (WindowHandle, L1, C1, L2, C2, LN, CN)
**CHAPTER 17 LEGACY**

---

**Result**

If the window is valid and the specified parameters are correct, `move_rectangle` returns 2 (H_MSG_TRUE). If necessary an exception is raised.

---

open_window

**Module**

Foundation

---

```plaintext
open_textwindow ( : : Row, Column, Width, Height, BorderWidth, BorderColor, BackgroundColor, FatherWindow, Mode, Machine : WindowHandle )
```

**open_textwindow** is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **open_window** instead.

`open_textwindow` opens a new textual window, which can be used to perform textual input and output, as well as to perform output of images. All output (`write_string`, `read_string`, `disp_region`, etc.) is redirected to this window, if the same logical window number `WindowHandle` is used.

Besides the mouse cursor textual windows possess also a textual cursor which indicates the current writing position (more exactly: the lower left corner of the output string without consideration of descenders). Its position is indicated through an underscore or another type (the indication of this position may also be disabled (= default setting); cf. `set_tshape`). You may set or query the position by calling the operators `set_tposition` or `get_tposition`.

After you opened a textual window the position of the cursor is set to (H,0). Whereby H signifies the height of the default font less the descenders. But the cursor is not shown. Hence the output starts for writing in the upper left corner of the window.

You may query the colors of the background and the image edges by calling `query_color`. In the same way you may use `query_color` in a window of type ‘invisible’. During output (`write_string`) you may set the clipping of text out of the window edges by calling `set_check(’∼text’:). This disables the creation of error messages, if text passes over the edge of the window.

The origin of the coordinate system of the window resides in the upper left corner (coordinates: (0,0)). The row index grows downward (maximal: `Height`-1), the column index grows to the right (maximal: `Width`-1).

The parameter `Machine` indicates the name of the computer, which has to open the window. In case of a X-window, TCP-IP only sets the name, DEC-Net sets in addition a colon behind the name. The “server” or the “screen”, respectively, are not specified. If the empty string is passed the environment variable DISPLAY is used. It indicates the target computer. At this the name is indicated in common syntax

```
<Host>:0.0
```

For windows of type ’WIN32-Window’, ’X-Window’, and ’Cocoa’ the parameter `FatherWindow` can be used to determine the father window for the window to be opened. In case the control ’father’ is set via `set_check`, `FatherWindow` must be the ID of a HALCON window, otherwise (`set_check(’∼father’)`) it can also be the
ID of an operating system window. If \texttt{FatherWindow} is passed the value 0 or \textquoteleft root', then under Windows and Unix-like systems the desktop and the root window become the father window, respectively. In this case, the value of the control \textquoteleft father' (set via \texttt{set_check}) is irrelevant. The caller must ensure that \texttt{FatherWindow} is a valid handle and not destroyed as long as the embedded HALCON window is used.

Position and size of a window may change during runtime of a program. This may be achieved by calling \texttt{set_window_extents}, but also through external interferences (window manager). In the latter case the operator \texttt{set_window_extents} is provided.

Opening a window causes the assignment of a called default font. It is used in connection with operators like \texttt{write_string} and you may overwrite it by performing \texttt{set_font} after calling \texttt{open_textwindow}. On the other hand you have the possibility to specify a default font by calling \texttt{set_system::
\textquoteleft default_font',<Fontname>
\textquoteleft

You may set the color of the font (\texttt{write_string, read_string}) by calling \texttt{set_color, set_rgb, set_hsi or set_gray}. Calling \texttt{set_insert} specifies how the text or the graphics, respectively, is combined with the content of the image repeat memory. So you may achieve by calling, e.g., \texttt{set_insert::
\textquoteleft

to eliminate the font after writing text twice at the same position.

Normally every output (e.g., \texttt{write_string, disp_region, disp_circle, etc.}) in a window is terminated by a \textquoteleft flush\textquoteleft. This causes the data to be fully visible on the display after termination of the output operator. But this is not necessary in all cases, in particular if there are permanently output tasks or there is a mouse procedure active. Therefore it is more favorable (i.e., more rapid) to store the data until sufficient data is available. You may stop this behavior by calling \texttt{set_system::
\textquoteleft

The content of windows is saved (in case it is supported by special driver software); i.e., it is preserved, also if the window is hidden by other windows. But this is not necessary in all cases: If you use a textual window, e.g., as a parent window for other windows, you may suppress the security mechanism for it and save the necessary memory at the same moment. You achieve this before opening the window by calling \texttt{set_system::
\textquoteleft

Difference: graphical window - textual window

- In contrast to graphical windows \texttt{(open_window)} you may specify more parameters (color, edge) for a textual window while opening it.
- You may use textual windows only for input of user data \texttt{(read_string)}.
- Using textual windows, the output of images, regions and graphics is \textquoteleft clipped\textquoteleft at the edges. Whereas during the use of graphical windows the edges are \textquoteleft zoomed\textquoteleft.
- The coordinate system (e.g., with \texttt{get_mbutton or get_mposition}) consists of display coordinates independently of image size. The maximum coordinates are equal to the size of the window minus 1. In contrast to this, graphical windows \texttt{(open_window)} use always a coordinate system, which corresponds to the image format.

The parameter \texttt{Mode} specifies the mode of the window. It can have following values:

\textquoteleft visible\textquoteleft: Normal mode for textual windows: The window is created according to the parameters and all inputs and outputs are possible.

\textquoteleft invisible\textquoteleft: Invisble windows are not displayed in the display. Parameters like \texttt{Row, Column, BorderWidth, BorderColor, BackgroundColor} and \texttt{FatherWindow} do not have any meaning. Output to these windows has no effect. Input \texttt{(read_string, mouse, etc.) is not possible. You may use these windows to query representation parameter for an output device without opening a (visible) window. General queries are, e.g., \texttt{query_color} and \texttt{get_string_extents}.

\textquoteleft transparent\textquoteleft: These windows are transparent: the window itself is not visible (edge and background), but all the other operations are possible and all output is displayed. Parameters like \texttt{BorderColor} and \texttt{BackgroundColor} do not have any meaning. A common use for this mode is the creation of mouse sensitive regions.

\textquoteleft buffer\textquoteleft: These are also not visible windows. The output of images, regions and graphics is not visible on the display, but is stored in memory. Parameters like \texttt{Row, Column, BorderWidth, BorderColor, BackgroundColor} and \texttt{FatherWindow} do not have any meaning. You may use buffer windows, if you prepare output (in the background) and copy it finally with \texttt{copy_rectangle} in a visible window. Another usage might be the rapid processing of image regions during interactive manipulations. Textual input and mouse interaction are not possible in this mode.
Attention

You have to keep in mind that parameters like Row, Column, Width and Height are restricted by the output device. If a father window (FatherWindow <> 'root') specified, then the coordinates are relative to this window.

**Parameters**

- **Row** (input_control): Row index of upper left corner.
  - Default value: 0
  - Typical range of values: 0 ≤ Row (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: Row ≥ 0

- **Column** (input_control): Column index of upper left corner.
  - Default value: 0
  - Typical range of values: 0 ≤ Column (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: Column ≥ 0

- **Width** (input_control): Window’s width.
  - Default value: 256
  - Typical range of values: 0 ≤ Width (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: Width > 0

- **Height** (input_control): Window's height.
  - Default value: 256
  - Typical range of values: 0 ≤ Height (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: Height > 0

- **BorderWidth** (input_control): Window border’s width.
  - Default value: 2
  - Typical range of values: 0 ≤ BorderWidth (lin)
  - Minimum increment: 1
  - Recommended increment: 1
  - Restriction: BorderWidth ≥ 0

- **BorderColor** (input_control): Window border’s color.
  - Default value: ‘white’

- **BackgroundColor** (input_control): Background color.
  - Default value: ‘black’

- **FatherWindow** (input_control): Logical number of the father window. For the display as father you may specify 'root' or 0.
  - Default value: 0
  - Restriction: FatherWindow ≥ 0

- **Mode** (input_control): Window mode.
  - Default value: ‘visible’
  - List of values: Mode ∈ {'visible', 'invisible', 'transparent', 'buffer'}

- **Machine** (input_control): Computer name, where the window has to be opened or empty string.
  - Default value: “
WindowHandle (output_control) ................................. window  \( \rightarrow \) handle

Window handle.

Example

```halcon
open_textwindow(0,0,900,600,1,'black','slate blue','root','visible', \
                 '',WindowHandle1)
open_textwindow(10,10,300,580,3,'red','blue',WindowHandle1,'visible', \
                 '',WindowHandle2)
open_window(10,320,570,580,WindowHandle1,'visible',',',WindowHandle)
set_color(WindowHandle1,'red')
read_image(Image,'monkey')
disp_image(Image,WindowHandle)
Button := 0
repeat
  try
    get_mposition(WindowHandle,Row,Column,Button)
    get_grayval(Image,Row,Column,Gray)
    write_string(WindowHandle2,[' Position (',Row,',',Column,') '])
    write_string(WindowHandle2,['Gray value (',Gray,') '])
    new_line(WindowHandle2)
  catch (Exception)
  endtry
until(Button == 4)
close_window(WindowHandle1)
```

Result

If the values of the specified parameters are correct open_textwindow returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Query the possible graphic modes.
**query_insert** is obsolete and is only provided for reasons of backward compatibility.

query_insert returns the possible modes pixels can be displayed in the output window. New pixels may e.g. overwrite old ones. In most of the cases there is a functional relationship between old and new values.

Possible display functions:

'copy': overwrite displayed pixels
'xor': display old “xor” new pixels
'complement': complement displayed pixels

“copy” is always available.

---

**Parameters**

- WindowHandle (input_control) \( \rightarrow \) window handle
- Mode (output_control) string-array \( \rightarrow \) string

---

**Result**

query_insert returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Possible Successors**

set_insert, disp_region

---

**Module**

Foundation

---

**query_tshape** ( : WindowHandle : TextCursor )

Query all shapes available for text cursors.

**query_tshape** is obsolete and is only provided for reasons of backward compatibility.

query_tshape queries the available shapes of text cursors for the output window. The retrieved shapes can be used by the operator set_tshape.

---

**Parameters**

- WindowHandle (input_control) \( \rightarrow \) window handle
- TextCursor (output_control) string-array \( \rightarrow \) string

---

**Result**

query_tshape returns 2 (H_MSG_TRUE).

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
set_comprise ( : : WindowHandle, Mode : )

Define the image matrix output clipping.

set_comprise is obsolete and is only provided for reasons of backward compatibility.

set_comprise defines the image matrix output clipping. If Mode is set to 'object', only gray values belonging
to the output object are displayed. If set to 'image', the whole image matrix is displayed. Default is 'object'.

Attention
If Mode was set to 'image', undefined gray values may be displayed. Depending on the context they are black or
can have random content. See the examples.

Parameters

▷ WindowHandle (input_control) ........................................ window  ↦ handle
  Window handle.

▷ Mode (input_control) ............................................... string  ↦ string
  Clipping mode for gray value output.
  Default value: 'object'
  List of values: Mode ∈ {'image', 'object'}

Example

read_image(Image,'fabrik')
gen_circle (Circle, 200, 200, 100.5)
reduce_domain (Image, Circle, ImageReduced)
set_system('init_new_image','false')
sobel_amp(ImageReduced,SobelReduced,'sum_abs',3)
devo_display (SobelReduced)
get_comprise(WindowHandle,Mode)
set_comprise(WindowHandle,'image')
stop ()
devo_display (SobelReduced)

Result
set_comprise returns 2 (H_MSG_TRUE) if Mode is correct and the window is valid. Otherwise an exception
is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

Possible Successors
set_fix ( : : WindowHandle, Mode : )

Set fixing of “look-up-table” (lut)

set_fix is obsolete and is only provided for reasons of backward compatibility.

Behaviour for Mode = 'true': set_fix fixes that pixel lastly ascertained by one of the operators set_gray, set_color, set_hsi or set_rgb (Remark: Here a pixel is the index within the current look-up-table). To assign a new color to a fixed pixel set a color or gray value by using set_color, set_rgb, set_hsi or set_gray. This makes it possible to define any color (set_color), any gray value (set_gray) and any color combination (set_rgb, set_hsi) at any position of the look-up-table.

Mode set to ‘false’ reset the fixing. To modify or create a look-up-table process set_pixel, set_fix(::WindowHandle,’true’), set_rgb and set_fix(::WindowHandle,’false’) one after another.

Attention

As a side effect set_fix can change colors of “non-HALCON windows”.

Parameters

- WindowHandle (input_control) Window handle.
- Mode (input_control) Mode of fixing.

Default value: 'true'

List of values: Mode ∈ {'true', 'false'}

Result

set_fix returns 2 (H_MSG_TRUE) if the window is valid, the hardware supports a look-up-table and all parameters are correct. Otherwise an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_fix

Possible Successors

set_pixel, set_rgb

See also

get_fix, set_pixel, set_rgb, set_color, set_hsi, set_gray

set_fixed_lut ( : : WindowHandle, Mode : )

Fix “look-up-table” (lut) for “real color images”.

set_fixed_lut is obsolete and is only provided for reasons of backward compatibility.

Fix “look-up-table” (lut) for “real color images”.

17.7. GRAPHICS

Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Mode** (input_control)  
  Mode of fixing.
  Default value: 'true'
  List of values: Mode ∈ {'true', 'false'}

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- get_fixed_lut

Foundation

**set_insert** ( : : WindowHandle, Mode : )

Define the pixel output function.

**set_insert** is obsolete and is only provided for reasons of backward compatibility.

**set_insert** defines the function, with which pixels are displayed in the output window. It is e.g. possible for a pixel to overwrite the old value. In most of the cases there is a functional relationship between old and new values.

The definition value is only valid for the valid window. Output operators that honor **Mode** are e.g. **disp_region**, **disp_polygon**, **disp_circle**.

Possible display functions are:

- 'copy': overwrite displayed pixels
- 'xor': display old "xor" new pixels
- 'complement': complement displayed pixels

There may not be all functions available, depending on the physical display. However, "copy" is always available.

Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Mode** (input_control)  
  Name of the display function.
  Default value: 'copy'
  List of values: Mode ∈ {'copy', 'xor', 'complement'}

Result

**set_insert** returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
set_line_approx ( : : WindowHandle, Approximation : )

**Define the approximation error for contour display.**

set_line_approx is obsolete and is only provided for reasons of backward compatibility.

set_line_approx defines the approximation error for region and xld contour display in the window WindowHandle. Approximation values greater than zero cause an approximation of line strokes using less points. This may enable faster and in some cases smoother visualization. The parameter describes the maximal deviation in pixels of the approximated contour from the original contour (Ramer-Douglas-Peucker algorithm).

**Parameters**

- **WindowHandle** (input_control) Window handle.
- **Approximation** (input_control) Maximum deviation from the original contour.
  
  **Default value:** 0
  
  **Typical range of values:** $0 \leq \text{Approximation}$
  
  **Restriction:** Approximation $\geq 0$

**Example**

* Calling...

set_line_approx(WindowHandle, Approximation)
set_draw(WindowHandle, 'margin')
disp_region(Obj, WindowHandle)

* ...corresponds with

get_region_polygon(Obj, Approximation, Row, Col)
disp_polygon(WindowHandle, Row, Col)

**Result**

set_line_approx returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_line_approx, set_line_style, set_draw, disp_region, disp_polygon

Module

set_lut_style ( : : WindowHandle, Hue, Saturation, Intensity : )

Changing the look-up-table (lut).

set_lut_style is obsolete and is only provided for reasons of backward compatibility.

set_lut_style changes the look-up-table (lut) of the device displaying the valid output window. It has got three parameters:

Hue: Rotation of color space, Hue = 1.9 conforms to a one-time rotation of the color space. No change: Hue = 0.0 Complement colors: Hue = 0.5

Saturation: Change of saturation, No change: Saturation = 1.0 Gray value image: Saturation = 0.0

Intensity: Change of intensity, No change: Intensity = 1.0 Black image: Intensity = 0.0

Changing affects only the part of an look-up-table that is used for displaying images. The parameter of modification remain until the next call of set_lut_style. Calling set_lut has got no effect on these parameters.

Parameters

▷ WindowHandle (input_control) ........................................... window ~ handle
Window handle.

▷ Hue (input_control) ......................................................... real ~ real
Modification of color value.
Default value: 0.0
Typical range of values: 0.0 <= Hue <= 1.0
Restriction: 0.0 >= Hue && Hue <= 1.0

▷ Saturation (input_control) ............................................... real ~ real
Modification of saturation.
Default value: 1.5
Typical range of values: 0.0 <= Saturation
Restriction: 0.0 <= Saturation

▷ Intensity (input_control) ............................................... real ~ real
Modification of intensity.
Default value: 1.5
Typical range of values: 0.0 <= Intensity
Restriction: 0.0 <= Intensity

Example

read_image(Image,'monkey')
dev_set_lut('color1')
repeat
  get_mbutton(WindowHandle,Row,Column,Button)
  Saturation := Row/300.0
  Hue := Column/512.0
  set_lut_style(WindowHandle,Hue,Saturation,1.0)
dev_display(Image)
until(Button == 4)

Result

set_lut_style returns 2 (H_MSG_TRUE) if the window is valid and the parameter is correct. Otherwise an exception is raised.

Parallelization

HALCON 20.05.0.0
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

set_pixel ( : : WindowHandle, Pixel : )

Define a color lookup table index.

set_pixel is obsolete and is only provided for reasons of backward compatibility.

set_pixel sets pixel values: colors (set_color, set_rgb, etc.) and gray values (set_gray) are coded together into a number, called pixel. This 'pixel' is an index in the color lookup table. It ranges from 0 to 1 in b/w images and 0 to 255 color images with 8 bit planes. It is different from the 'pixel' ('picture element') in image processing. Therefore HALCON distinguishes between pixel and image element (or gray value).

The current value can be queried with get_pixel.

Parameters

▷ WindowHandle (input_control) .......... window ~ handle
   Window handle.

▷ Pixel (input_control) ............... integer(-array) ~ integer
   Color lookup table index.
   Default value: 128
   Typical range of values: 0 ≤ Pixel ≤ 255

Result

set_pixel returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
**set_tshape** ( : : WindowHandle, TextCursor : )

Set the shape of the text cursor.

*set_tshape* is obsolete and is only provided for reasons of backward compatibility.

`set_tshape` sets the shape and the display mode of the text cursor of the output window.

A text cursor marks the current position for text output. It is different from the mouse cursor (although both will be called 'cursor', if the context makes misconceptions impossible). The available shapes for the text cursor can be queried with `query_tshape`.

---

**Parameters**

- **WindowHandle** (input_control) window handle.
- **TextCursor** (input_control) Name of cursor shape.

**Default value:** 'invisible'

**Result**

`set_tshape` returns 2 (H_MSG_TRUE) if the window is valid and the given cursor shape is defined for this window. Otherwise an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Foundation

---

**slide_image** ( : : WindowHandleSource1, WindowHandleSource2, WindowHandle : )

Interactive output from two window buffers.

The operator `slide_image` does not work with HDevelop graphics windows. It is only provided for reasons of backward compatibility.

`slide_image` divides the window horizontal in two logical areas dependent of the mouse position. The content of the first indicated window is copied in the upper area, the content of the second window is copied in the lower area. If you press the left mouse button you may scroll the delimitation between the two areas (you may move the mouse outside the window, too. In doing so the position of the mouse relative to the window determines the borderline).

Pressing the right mouse button in the window terminates the operator `slide_image`.

A useful application of the operator `slide_image` might be the visualization of the effect of a filtering operation for an image. The output is directed to the currently set window (`WindowHandle`).

---

**Attention**

The three windows must have the same size and have to reside on the same computer.
Parameters

- **Win\-dowHandleSource1** (input_control) window \( \rightarrow \) handle
  Source window handle of the "upper window".
- **Win\-dowHandleSource2** (input_control) window \( \rightarrow \) handle
  Source window handle of the "lower window".
- **WindowHandle** (input_control) window \( \rightarrow \) handle
  Output window handle.

Example

```
read_image (Image, 'fabrik')
sobel_dir (Image, EdgeAmplitude, EdgeDirection, 'sum_abs', 3)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle1)
dev_display (EdgeAmplitude)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle2)
dev_display (EdgeDirection)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
slide_image (WindowHandle1, WindowHandle2, WindowHandle)
```

Result

If the both windows exist and one of these windows is valid `slide_image` returns 2 (H MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- `open_window`

Alternatives

- `copy_rectangle`, `get_mposition`

See also

- `open_window`, `move_rectangle`

Module

Foundation

**write_lut** ( : : WindowHandle, FileName : )

Write look-up-table (lut) as file.

**write_lut** is obsolete and is only provided for reasons of backward compatibility.

**write_lut** saves the look-up-table (resp. the part of it that is relevant for displaying image gray values) of the valid output window into a file named `FileName.lut`. It can be read again later with `set_lut`.

Attention

**write_lut** is only suitable for systems using 256 colors.

Parameters

- **WindowHandle** (input_control) window \( \rightarrow \) handle
  Window handle.
- **FileName** (input_control) filename.write \( \sim \) string
  File name (of file containing the look-up-table).
  Default value: '/tmp/lut'
  File extension: .lut
17.8. MATCHING

write_lut returns 2 (H_MSG_TRUE) if the window with the required properties (256 colors) is valid and the parameter (file name) is correct. Otherwise an exception is raised.

---

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

Possible Predecessors

set_lut

---

Module

Foundation

17.8 Matching

adapt_template ( Image : , TemplateID : )

Adapting a template to the size of an image.

adapt_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator adapt_template serves to adapt a template which has been created by create_template to the size of an image. The operator adapt_template can be called before the template is used with images of another size, or if the image used to create the template had another size. If it is not called explicitly it will be called internally each time another image size is used. The contents of the image is hereby irrelevant; only the width of Image will be considered.

---

Parameters

- **Image** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . singlechannelimage(-array) \( \sim \) object : byte
  Image which determines the size of the later matching.
- **TemplateID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . template \( \sim \) handle
  Template number.

---

Result

If the parameter values are correct, the operator adapt_template returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **TemplateID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

Possible Predecessors

create_template, create_template_rot, read_template

---

Possible Successors

set_reference_template, best_match, fast_match, fast_match_mg,
set_offset_template, best_match_mgmt, best_match_pre_mgmt, best_match_rot_mgmt

---

**Module**

**best_match** ( Image : : TemplateID, MaxError, SubPixel : Row, Column, Error )

**Searching the best matching of a template and an image.**

**best_match** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **best_match** performs a matching of the template of **TemplateID** and **Image**. Hereby the template will be moved over the points of **Image** so that the template will lie always inside **Image**. **best_match** works similar to **fast_match**, with the exception, that each time a better match is found the value of **MaxError** is internally updated to a lower value to reduce runtime.

With regard to the parameter **SubPixel**, the position will be indicated by subpixel accuracy. The matching criterion (“displaced frame difference”) is defined as follows:

\[
\text{error}_{\text{row}, \text{col}} = \frac{\sum_{u,v} |\text{Image}_{\text{row} - u, \text{col} - v} - \text{TemplateID}_{u,v}|}{\text{area(TemplateID)}}
\]

The runtime of the operator depends on the size of the domain of **Image**. Therefore it is important to restrict the domain as far as possible, i.e. to apply the operator only in a very confined “region of interest”. The parameter **MaxError** determines the maximal error which the searched position is allowed to have at most. The lower this value is, the faster the operator runs.

**Row** and **Column** return the position of the best match, whereby **Error** indicates the average difference of the grayvalues. If no position with an error below **MaxError** was found the position \((0, 0)\) and a matching result of 255 for **Error** are returned. In this case **MaxError** has to be set larger.

The maximum error of the position (without noise) is 0.1 pixel. The average error is 0.03 pixel.

---

**Parameters**

- **Image** (input_object) ................................................................. singlechannelimage(-array) \(\sim\) object : byte
  Input image inside of which the pattern has to be found.

- **TemplateID** (input_control) .................................................... template \(\sim\) handle
  Template number.

- **MaxError** (input_control) .......................................................... real \(\sim\) real
  Maximum average difference of the grayvalues.
  Default value: 20.0
  Suggested values: MaxError \(\in\) \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0\}
  Typical range of values: \(0 \leq \text{MaxError} \leq 255\)
  Minimum increment: 1
  Recommended increment: 3

- **SubPixel** (input_control) ....................................................... string \(\sim\) string
  Subpixel accuracy in case of ‘true’.
  Default value: ‘false’
  List of values: **SubPixel** \(\in\) \{‘true’, ‘false’\}

- **Row** (output_control) ............................................................... point.y(-array) \(\sim\) real
  Row position of the best match.

- **Column** (output_control) .......................................................... point.x(-array) \(\sim\) real
  Column position of the best match.

- **Error** (output_control) .............................................................. real(-array) \(\sim\) real
  Average divergence of the grayvalues of the best match.
If the parameter values are correct, the operator `best_match` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behaviour can be set via `set_system` ('no_object_result',<Result>). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

`Matching`

---

**best_match_mg**

```plaintext```
(Image : : TemplateID, MaxError, SubPixel,
 NumLevels, WhichLevels : Row, Column, Error )
```plaintext```

*Searching the best gray value matches in a pyramid.*

`best_match_mg` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`best_match_mg` applies gray value matching using an image pyramid. `best_match_mg` works analogously to `best_match`, but it is faster due to the use of a pyramid. Input is an image with an optionally reduced domain. The template is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image.

The parameter `MaxError` specifies the maximum error for template matching. Using smaller values results in a reduced runtime but it is possible that the pattern might be missed. The value of `MaxError` has to be chosen larger compared with `best_match`, because the error at higher levels of the pyramid is often larger.

`SubPixel` specifies if the result is calculated with sub pixel accuracy or not. A value of 1 for `NumLevels` results in an operator similar to `best_match`, i.e. only the original gray values are used. For values larger than 1, the algorithm starts at the lowest resolution and searches for a position with the lowest matching error. At the next higher resolution this position is refined. This is continued up to the maximum resolution (`WhichLevels = 'all'`). As an alternative Method the mode `WhichLevels` with value 'original' can be used. In this case not only the position with the lowest error but all points below `MaxError` are analyzed further on in the next higher resolution. This method is slower but it is more stable and the possibility to miss the correct position is very low. In this case it is often possible to start with a lower resolution (higher level in Pyramid, i.e. larger value for `NumLevels`) which leads to a reduced runtime. Besides the values in `WhichLevels` you can specify the pyramid level explicitly where to switch between a "match all" and the "best match". Here 0 corresponds to 'original' and `NumLevels` - 1 is equivalent to 'all'. A value in-between is in most cases a good compromise between speed and a stable detection. A larger value for `WhichLevels` results in a reduced runtime, a smaller value results in a more stable detection. The value of `NumLevels` has to be equal or smaller than the value used to create the template.

The position of the found matching position is returned in `Row` and `Column`. The corresponding error is given in `Error`. If no point below `MaxError` is found a value of 255 for `Error` and 0 for `Row` and `Column` is returned. If the desired object is missed (no object found or wrong position) you have to set `MaxError` higher or `WhichLevels` lower. Check also if the illumination has changed (see `set_offset_template`).

The maximum error of the position (without noise) is 0.1 pixel. The average error is 0.03 pixel.
**Parameters**

- **Image** (input_object)  
  Input image inside of which the pattern has to be found.

- **TemplateID** (input_control)  
  Template number.

- **MaxError** (input_control)  
  Maximal average difference of the grayvalues.  
  **Default value:** 30.0 
  **Suggested values:** MaxError ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0} 
  **Typical range of values:** 0 ≤ MaxError ≤ 255 
  **Minimum increment:** 1 
  **Recommended increment:** 3

- **SubPixel** (input_control)  
  Exactness in subpixels in case of 'true'.  
  **Default value:** 'false' 
  **List of values:** SubPixel ∈ {'true', 'false'}

- **NumLevels** (input_control)  
  Number of the used resolution levels.  
  **Default value:** 4 
  **Suggested values:** NumLevels ∈ {1, 2, 3, 4, 5, 6}

- **WhichLevels** (input_control)  
  Resolution level up to which the method "best match" is used.  
  **Default value:** 2 
  **Suggested values:** WhichLevels ∈ {'all', 'original', 0, 1, 2, 3, 4, 5, 6}

- **Row** (output_control)  
  Row position of the best match.  
  **Default value:**

- **Column** (output_control)  
  Column position of the best match.

- **Error** (output_control)  
  Average divergence of the grayvalues in the best match.

**Result**

If the parameter values are correct, the operator best_match_mg returns the value 2 (H_MSG_TRUE). 
If the input is empty (no input images are available) the behaviour can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Predecessors**

create_template, read_template, adapt_template, draw_region, draw_rectangle1, reduce_domain, set_reference_template, set_offset_template

---

**Alternatives**

fast_match, fast_match_mg, best_match, best_match_pre_mg, best_match_rot, best_match_rot_mg, exhaustive_match, exhaustive_match_mg

---

**Module**

**best_match_pre_mg**  
( ImagePyramid : : TemplateID, MaxError,  
  SubPixel, NumLevels, WhichLevels : Row, Column, Error )

Searching the best gray value matches in a pre generated pyramid.
**best_match_pre_mg** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

**best_match_pre_mg** applies gray value matching using an image pyramid. **best_match_pre_mg** works analogously to **best_match_mg**, but it makes use of pre calculated pyramid which has to be generated beforehand using **gen_gauss_pyramid**. This reduces runtime if more than one match has to be done or the pyramid has been used otherwise. The pyramid has to be generated using the zooming factor 0.5 and the mode 'constant'.

---

**Parameters**

- **ImagePyramid** (input_object) singlechannelimage-array object: byte
  Image pyramid inside of which the pattern has to be found.
- **TemplateID** (input_control) template handle
  Template number.
- **MaxError** (input_control) real real
  Maximal average difference of the grayvalues.
  **Default value:** 30.0
  **Suggested values:** MaxError ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
  **Typical range of values:** 0 ≤ MaxError ≤ 255
  **Minimum increment:** 1
  **Recommended increment:** 3
- **SubPixel** (input_control) string string
  Exactness in subpixels in case of 'true'.
  **Default value:** 'false'
  **List of values:** SubPixel ∈ {'true', 'false'}
- **NumLevels** (input_control) integer integer
  Number of the used resolution levels.
  **Default value:** 3
  **Suggested values:** NumLevels ∈ {1, 2, 3, 4, 5, 6}
- **WhichLevels** (input_control) integer / string
  Resolution level up to which the method “best match” is used.
  **Default value:** 'original'
  **Suggested values:** WhichLevels ∈ {'all', 'original', 0, 1, 2, 3, 4, 5, 6}
- **Row** (output_control) point.y real
  Row position of the best match.
- **Column** (output_control) point.x real
  Column position of the best match.
- **Error** (output_control) real real
  Average divergence of the grayvalues in the best match.

---

**Result**

If the parameter values are correct, the operator **best_match_pre_mg** returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behaviour can be set via **set_system** ('no_object_result',<Result>). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Possible Predecessors**

---

**Alternatives**

- **fast_match**, **fast_match_mg**, **exhaustive_match**, **exhaustive_match_mg**

---

**Module**

Matching
Searching the best matching of a template and an image with rotation.

**best_match_rot** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **best_match_rot** performs a matching of the template of `TemplateID` and `Image`. It works similar to **best_match** with the extension that the pattern can be rotated. The parameters `AngleStart` and `AngleExtend` define the maximum rotation of the pattern: `AngleStart` specifies the maximum counter clockwise rotation and `AngleExtend` the maximum clockwise rotation relative to this angle. Both values have to smaller or equal to the values used for the creation of the pattern (see **create_template_rot**). In addition to **best_match** **best_match_rot** returns the rotation angle of the pattern in `Angle` (radians). The accuracy of this angle depends on the parameter `AngleStep` of **create_template_rot**. In the case of `SubPixel = 'true'` the position and the angle are calculated with “sub pixel” accuracy.

### Parameters

- **Image** (input_object) singlechannelimage(-array) \(\sim\) `object`: byte
  Input image inside of which the pattern has to be found.

- **TemplateID** (input_control) template `\sim` handle
  Template number.

- **AngleStart** (input_control) angle.rad \(\sim\) `real`
  Smallest Rotation of the pattern.
  Default value: -0.39
  Suggested values: `AngleStart \in [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]`

- **AngleExtend** (input_control) angle.rad \(\sim\) `real`
  Maximum positive Extension of `AngleStart`.
  Default value: 0.79
  Suggested values: `AngleExtend \in [6.28, 3.14, 1.57, 0.79, 0.39]`
  Restriction: `AngleExtend > 0`

- **MaxError** (input_control) real \(\sim\) `real`
  Maximum average difference of the grayvalues.
  Default value: 30.0
  Suggested values: `MaxError \in [0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0]`
  Typical range of values: \(0 \leq\) `MaxError` \(\leq 255\)
  Minimum increment: 1
  Recommended increment: 3

- **SubPixel** (input_control) string \(\sim\) `string`
  Subpixel accuracy in case of `'true'`.
  Default value: `'false'`
  List of values: `SubPixel \in ['true', 'false']`

- **Row** (output_control) point.y(-array) \(\sim\) `real`
  Row position of the best match.

- **Column** (output_control) point.x(-array) \(\sim\) `real`
  Column position of the best match.

- **Angle** (output_control) angle.rad(-array) \(\sim\) `real`
  Rotation angle of pattern.

- **Error** (output_control) real(-array) \(\sim\) `real`
  Average divergence of the grayvalues of the best match.

**Result**

If the parameter values are correct, the operator **best_match_rot** returns the value 2 (H_MSG_TRUE).

If the input is empty (no input images are available) the behaviour can be set via **set_system** (`'no_object_result',<Result>`). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

best_match_rot, best_match_mg

Module

best_match_rot_mg ( Image : TemplateID, AngleStart, AngleExtend, MaxError, SubPixel, NumLevels : Row, Column, Angle, Error )

Searching the best matching of a template and a pyramid with rotation.

best_match_rot_mg is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator best_match_rot_mg performs a matching of the template of TemplateID and Image. It works similar to best_match_mg with the extension that the pattern can be rotated analogously to best_match_rot. The parameters AngleStart and AngleExtend define the maximum rotation of the pattern: AngleStart specifies the maximum counter clockwise rotation and AngleExtend the maximum clockwise rotation relative to this angle. Both values have to smaller or equal to the values used for the creation of the pattern (see create_template_rot). In addition to best_match_mg best_match_rot_mg returns the rotation angle of the pattern in Angle (radian).

The value of MaxError must be set larger in comparison with the operator best_match_rot, because often the error is larger at higher levels of the pyramid.

In the case of SubPixel = 'true' the position and the angle are calculated with “sub pixel” accuracy.

The value of NumLevels has to equal or smaller than the value used to create the template.

Parameters

▷ Image (input_object) .................. singlechannelimage(-array)  \( \sim \) object : byte
Input image inside of which the pattern has to be found.
▷ TemplateID (input_control) ........... template \( \sim \) handle
Template number.
▷ AngleStart (input_control) .............. angle.rad \( \sim \) real
Smallest Rotation of the pattern.
  Default value: -0.39
  Suggested values: AngleStart \( \in \) \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}
▷ AngleExtend (input_control) .............. angle.rad \( \sim \) real
Maximum positive Extension of AngleStart.
  Default value: 0.79
  Suggested values: AngleExtend \( \in \) \{6.28, 3.14, 1.57, 0.79, 0.39\}
  Restriction: AngleExtend \( \geq \) 0
▷ MaxError (input_control) ................. real \( \sim \) real
Maximum average difference of the grayvalues.
  Default value: 40.0
  Suggested values: MaxError \( \in \) \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0\}
  Typical range of values: \( 0 \leq \) MaxError \( \leq 255 \)
  Minimum increment: 1
  Recommended increment: 1

HALCON 20.05.0.0
SubPixel (input_control) ................................. string ∼ string
Subpixel accuracy in case of 'true'.
Default value: 'false'
List of values: SubPixel ∈ ['true', 'false']

NumLevels (input_control) .............................. integer ∼ integer
Number of the used resolution levels.
Default value: 3
Suggested values: NumLevels ∈ {1, 2, 3, 4, 5, 6}

Row (output_control) ................................. point.y(-array) ∼ real
Row position of the best match.

Column (output_control) .............................. point.x(-array) ∼ real
Column position of the best match.

Angle (output_control) .............................. angle.rad(-array) ∼ real
Rotation angle of pattern.

Error (output_control) .............................. real(-array) ∼ real
Average divergence of the grayvalues of the best match.

If the parameter values are correct, the operator best_match_rot_mg returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behaviour can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Matching

clear_template ( : : TemplateID : )

Deallocation of the memory of a template.
clear_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator clear_template deallocates the memory of a template which has been created by create_template or create_template_rot. After execution of the operator clear_template the template can no longer be used. The value of TemplateID is not valid. However, the number can be used again by further calls of create_template or create_template_rot.

TemplateID (input_control) ............................. template ∼ handle
Template number.

If the number of the template is valid, the operator clear_template returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.
匹配

- 多线程类型：重新入式（与其他非互斥操作在并行运行）。
- 多线程范围：全局（可由任意线程调用）。
- 未处理的并行化。

此操作修改以下输入参数的状态：

- TemplateID

在执行此操作期间，必须同步使用此参数的值，如果它在多个线程中被使用。

可能的前驱

create_template, create_template_rot, read_template, write_template

模块

prepare_pattern_for_template_matching.

create_template 是已废弃的，并且仅用于因后向兼容性原因而提供的旧应用程序。

new_applications 应该使用基于形状或NCC的基于操作符。

create_template 预处理模式（Template），该模式作为图像传递，用于模板匹配。在转换之后，一个 (TemplateID) 被分配给模板以供在后续过程中使用。模板的形状和尺寸可以任意选择。您必须意识到，匹配仅应用于图像中符合的模板部分。

模板已被选择，使得它不包含变化背景的像素。您可以使用任意形状的模板，而不仅仅受限于矩形。您可以通过应用threshold或其中的一个 draw_* 操作符来创建模板区域。在亚像素精确匹配的情况下，Template 必须比模式小一个像素（即一个像素的边界到变化背景）。这可以通过应用操作符erosion_circle 来完成。

参数 NumLevel 指定可以用于匹配的金字塔级数（NumLevel = 1 表示仅使用原始灰度值）。用于匹配的级数将等于或小于此值。如果模式由于缩放而变得太小，则最多可能减少金字塔级数（没有错误信息）。

参数 GrayValues 定义，构造特征时使用原始灰度值（'original'）或边缘幅度（'gradient'）。

'original' 的优点是稳定且速度快，如果不存在光照变化。'normalized' 用于光照变化。

注意，'normalized' 允许补偿光照变化。如果存在多倍灰度值的乘法变化，则应该使用 correlation-based matching (create_ncc_model)。如果光照没有变化，则应使用模式 'original'

edge 幅度是另一种方法，可以对光照变化保持不变。缺点是执行时间的增加和更大噪声的敏感。

边缘幅度模式在匹配中通常会选择更高的最大误差。由GrayValues 选择的模式会自动调用适当的过滤器进行匹配，如果需要。

作为对梯度方法的替代，只要有光照变化，就可以使用 set_offset_template 操作符。

参数 Optimize 指定是否需要优化以提高运行时性能。优化导致创建模板所需的时间更长，但匹配时间减少。此外，优化可以提高匹配的稳定性，减少了误匹配的可能性。

refposition 为模板的位置，它是指其质心。即如果您将模板应用于原始图像，则质心将被返回。此默认参考可以使用 set_reference_template 操作符进行调整。

HALCON 20.05.0.0
In sub pixel mode a special position correction is calculated which is added after each matching: The template is applied to the original image and the difference between the found position and the center of gravity is used as a correction vector. This is important for patterns in a textured context or for asymmetric pattern. For most templates this correction vector is near null.

Before the use of the template, which is stored independently of the image size, it can be adapted explicitly to the size of a definite image size by using adapt_template.

### Parameters

**Result**

If the parameters are valid, the operator create_template returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Predecessors

draw_region, reduce_domain, threshold

### Possible Successors

adapt_template, set_reference_template, clear_template, write_template, set_offset_template, best_match, best_match_mg, fast_match, fast_match_mg

### Alternatives

create_ncc_model, create_template_rot, read_template

### Module

Matching

```c
create_template_rot ( Template : : NumLevel, AngleStart,
                      AngleExtend, AngleStep, Optimize, GrayValues : TemplateID )
```

Preparing a pattern for template matching with rotation.
create_template_rot is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator create_template_rot preprocesses a pattern, which is passed as an image, for the template matching. An extension to create_template the matching can applied to rotated patterns. The parameters AngleStart and AngleExtend define the maximum rotation of the pattern: AngleStart specifies the maximum counter clockwise rotation and AngleExtend the maximum clockwise rotation relative to this angle. Therefore AngleExtend has to be smaller than $2\pi$. With the parameter AngleStep the maximum angle resolution (on the highest resolution level) can be specified.

You have to be aware, that all possible rotations are calculated beforehand to reduce runtime during matching. This leads to a higher execution time for create_template_rot and high memory requirements for the template. The amount of memory depends on the parameters AngleExtend and AngleStep. The number of pyramid levels can be neglected. If $A$ is the number of pixels of Template, the memory $M$ needed for the template in byte is about:

$$M = A \times 12 \times \frac{\text{AngleExtend}}{\text{AngleStep}}$$

After the transformation, a number (TemplateID) is assigned to the template for being used in the further process.

A description of the other parameters can be found at the operator create_template.

---

Attention

You have to be aware, that depending on the resolution a large number of pre calculated patterns have to be created which might result in a large amount of memory needed.

17.8. MATCHING

fast_match ( Image : Matches : TemplateID, MaxError : )

Searching all good matches of a template and an image. fast_match is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator fast_match performs a matching of the template of TemplateID and Image. Hereby the template will be moved over the points of Image so that the template always lies completely inside of Image. The matching criterion (“displaced frame difference”) is defined as follows:

\[ error[row,col] = \frac{\sum_{u,v} |Image[row - u, col - v] - TemplateID[u,v]|}{area(TemplateID)} \]

The difference between fast_match and exhaustive_match is that the matching for one position is stopped if the error is too high. This leads to a reduced runtime but one might miss correct matches. The runtime of the operator depends mainly on the size of the domain of Image. Therefore it is important to restrict the domain as far as possible, i.e. to apply the operator only in a very confined “region of interest”. The parameter MaxError determines the maximal error which the searched position is allowed to show. The lower this value is, the faster the operator runs.

All points which show a matching error smaller than MaxError will be returned in the output region Matches. This region can be used for further processing. For example by using a connection and best_match to find all the matching objects. If no point has a match error below MaxError the empty region (i.e no points) is returned.

Parameters

- Image (input_object) .................................................. singlechannelimage(-array)  object : byte
  Input image inside of which the pattern has to be found.
- Matches (output_object) .................................................. region(-array)  object
  All points whose error lies below a certain threshold.
- TemplateID (input_control) .................................................. template  handle
  Template number.
- MaxError (input_control) .................................................. real  real
  Maximal average difference of the grayvalues.

  Default value: 20.0
  Suggested values: MaxError ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0}
  Typical range of values: 0 ≤ MaxError ≤ 255
  Minimum increment: 1
  Recommended increment: 1

Result

If the parameter values are correct, the operator fast_match returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behaviour can be set via set_system (’no_object_result’,<Result>). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

create_template, read_template, adapt_template, draw_region, draw_rectangle1, reduce_domain

Possible Successors

connection, best_match

Alternatives

best_match, best_match_mg, fast_match_mg, exhaustive_match, exhaustive_match_mg

Module

Matching
Searching all good gray value matches in a pyramid.

**fast_match_mg** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **fast_match_mg** like the operator **fast_match** performs a matching of the template of **TemplateID** and **Image**. In contrast to **fast_match**, however, the search for good matches starts in scaled down images (pyramid). The number of levels of the pyramid will be determined by **NumLevel**. Hereby the value 1 indicates that no pyramid will be used. In this case the operator **fast_match_mg** is equivalent to the operator **fast_match**. The value 2 triggers the search in the image with half the framesize. The search for all those points showing an error small enough in the scaled down image (error smaller than **MaxError**) will be refined at the corresponding positions in the original image (**Image**).

The runtime of matching depends on the parameter **MaxError**: the larger the value the longer is the processing time, because more points of the pattern have to be tested. If **MaxError** is to low the pattern will not be found. The value has therefore to be optimized for every application.

**NumLevel** indicates the number of levels of the pyramid, including the original image. Optionally a second value can be given. This value specifies the number (0..n) of the lowest level which is used the matching. The region found up to this level will then be zoomed to the size of the original level. This can used to increase the runtime in the case that the accuracy does not have to be so high.

---

### Parameters

- **Image** (input_object) singlechannelimage(-array)  
  Input image inside of which the pattern has to be found.
- **Matches** (output_object) region(-array)  
  All points which have an error below a certain threshold.
- **TemplateID** (input_control) template  
  Template number.
- **MaxError** (input_control) real  
  Maximal average difference of the grayvalues.  
  Default value: 30.0  
  Suggested values:  
  ,  
  Typical range of values:  
  Minimum increment: 1  
  Recommended increment: 3
- **NumLevel** (input_control) integer(-array)  
  Number of levels in the pyramid.  
  Default value: 3  
  Suggested values:  

---

### Result

If the parameter values are correct, the operator **fast_match_mg** returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behaviour can be set via **set_system** ('no_object_result',<Result>). If necessary, an exception is raised.

---

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

### Possible Predecessors

- create_template, read_template, adapt_template, draw_region, draw_rectangle1, reduce_domain

---

### Alternatives

- best_match, best_match_mg, fast_match, exhaustive_match, exhaustive_match_mg

### Module

**read_template** ( : : FileName : TemplateID )

Reading a template from file.

**read_template** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **read_template** reads a matching template from file which has been written with **write_template**. The default HALCON file extension for a template is `.gvt`.

#### Parameters

- **FileName** (input_control) ..................................................... filename.read → string
  
  File name.

  File extension: `.gvt`

- **TemplateID** (output_control) ............................................... template → handle
  
  Template number.

#### Result

If the file name is valid, the operator **read_template** returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

#### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

#### Possible Successors

### Module

**serialize_template** ( : : TemplateID : SerializedItemHandle )

Serialize a template.

**serialize_template** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

**serialize_template** serializes the data of a template (see **fwrite_serialized_item** for an introduction of the basic principle of serialization). The same data that is written in a file by **write_template** is converted to a serialized item. The template is defined by the handle **TemplateID**. The serialized template is returned by the handle **SerializedItemHandle** and can be deserialized by **deserialize_template**.

#### Parameters

- **TemplateID** (input_control) ............................................... template → handle
  
  Handle of the template.

- **SerializedItemHandle** (output_control) ............................. serialized_item → handle
  
  Handle of the serialized item.
If the parameters are valid, the operator `serialize_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `create_template`, `create_template_rot`

### Possible Successors

- `fwrite_serialized_item`, `send_serialized_item`, `deserialize_template`

### Module

Matching

---

**set_offset_template** ( : : TemplateID, GrayOffset : )

Gray value offset for template.

`set_offset_template` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`set_offset_template` adds a gray value offset to the template to eliminate gray value changes in the image. The parameter `GrayOffset` specifies a difference relative to the gray values of the pattern when it was created with `create_template` (not relative to the last call of `set_offset_template`). The values of `GrayOffset` has to be chosen according to the gray values of the image: A brighter image results in a positive value, a darker image results in a negative value. `set_offset_template` has to be called each time the gray values of the image changes. The gray values can be measured in a reference area using `intensity` or `min_max_gray`

#### Parameters

- **TemplateID** (input_control)  
  Template number.
- **GrayOffset** (input_control)  
  Offset of gray values.  
  Default value: 0  
  Suggested values: `GrayOffset ∈ {-10, -5, -2, -1, 0, 1, 2, 5, 10}`  
  Typical range of values: `-255 ≤ GrayOffset ≤ 255`  
  Minimum increment: 1  
  Recommended increment: 1

#### Result

If the parameter values are correct, the operator `set_offset_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **TemplateID**
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Parameters

- TemplateID (input_control)  handle
  Template number.
- Row (input_control)  point.y  real
  Reference position of template (row).
- Column (input_control)  point.x  real
  Reference position of template (column).

Result

If the parameter values are correct, the operator set_reference_template returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

write_template ( : : TemplateID, FileName : )

Writing a template to file.
write_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator write_template writes a matching template to file which can be read again with read_template. The default HALCON file extension for a template is ‘gvt’.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>◮ TemplateID (input_control)</td>
</tr>
<tr>
<td>◮ FileName (input_control)</td>
</tr>
</tbody>
</table>

File extension: .gvt

Result

If the file name is valid (permission to write), the operator write_template returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

create_template, create_template_rot

Module

17.9 Morphology

closing_golay ( Region : RegionClosing : GolayElement, Rotation : )

Close a region with an element from the Golay alphabet.

closing_golay is obsolete and is only provided for reasons of backward compatibility.

closing_golay is defined as a Minkowski addition followed by a Minkowski subtraction. First the Minkowski addition of the input region (Region) with the structuring element from the Golay alphabet defined by GolayElement and Rotation is computed. Then the Minkowski subtraction of the result and the structuring element rotated by 180° is performed.

The following structuring elements are available:

The rotation number Rotation determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

closing_golay serves to close holes smaller than the structuring element, and to smooth regions’ boundaries.

Attention

Not all values of Rotation are valid for any Golay element. For some of the values of Rotation, the resulting regions are identical to the input regions.

Parameters

◮ Region (input_object) region(-array) object |
Regions to be closed.

◮ RegionClosing (output_object) region(-array) object |
Closed regions.
17.9. MORPHOLOGY

GolayElement (input_control) ......................................................... string \( \rightarrow \) string

Structuring element from the Golay alphabet.

Default value: 'h'

List of values: GolayElement \( \in \{ 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k' \} \)

Rotation (input_control) .............................................................. integer \( \rightarrow \) integer

Rotation of the Golay element. Depending on the element, not all rotations are valid.

Default value: 0

List of values: Rotation \( \in \{ 0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15 \} \)

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \]

closing_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Multithreading scope: global (may be called from any thread).

Automatically parallelized on tuple level.

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

reduce_domain, select_shape, area_center, connection

closing

erosion_golay, dilation_golay, opening_golay, hit_or_miss_golay, thinning_golay, thickening_golay, golay_elements

Dilate a region with an element from the Golay alphabet.

dilation_golay is obsolete and is only provided for reasons of backward compatibility.

dilation_golay dilates a region with the selected element GolayElement from the Golay alphabet. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number Rotation determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements. The operator works by shifting the structuring element over the region to be processed (Region). For all positions of the structuring element that
intersect the region, the corresponding reference point (relative to the structuring element) is added to the output region. This means that the union of all translations of the structuring element within the region is computed. 

The parameter **Iterations** determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration $n$.

---

**Attention**

Not all values of **Rotation** are valid for any Golay element. For some of the values of **Rotation**, the resulting regions are identical to the input regions.

---

**Parameters**

- **Region** *(input_object)* region(-array) $\mapsto$ object
  Regions to be dilated.

- **RegionDilation** *(output_object)* region(-array) $\mapsto$ object
  Dilated regions.

- **GolayElement** *(input_control)* string $\mapsto$ string
  Structuring element from the Golay alphabet.
  Default value: 'h'
  List of values: GolayElement $\in$ \{'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'\}

- **Iterations** *(input_control)* integer $\mapsto$ integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations $\in$ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
  Typical range of values: $1 \leq$ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

- **Rotation** *(input_control)* integer $\mapsto$ integer
  Rotation of the Golay element. Depending on the element, not all rotations are valid.
  Default value: 0
  List of values: Rotation $\in$ \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}

---

**Complexity**

Let $F$ be the area of an input region. Then the runtime complexity for one region is:

$$O(3 \cdot \sqrt{F})$$

---

**Result**

dilation_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system(‘no_object_result’,<RegionResult>)
  ```

- empty region:
  ```
  set_system(‘empty_region_result’,<RegionResult>)
  ```

Otherwise, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

dilation_seq ( Region : RegionDilation : GolayElement,
              Iterations : )

Dilate a region sequentially.

dilation_seq is obsolete and is only provided for reasons of backward compatibility.

dilation_seq computes the sequential dilation of the input region Region with the selected structuring element GolayElement from the Golay alphabet. This is done by executing the operator dilation_golay with all rotations of the structuring element Iterations times. The following structuring elements can be selected: 'l', 'd', 'c', 'f', 'h', 'k'.

In order to compute the skeleton of a region, usually the elements 'l' and 'm' are used. Only the “foreground elements” (even rotation numbers) are used. The elements 'i' and 'e' result in unchanged output regions. The elements 'l', 'm' and 'f2' are identical for the foreground. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

Parameters

- **Region** (input_object) — Regions to be dilated.
- **RegionDilation** (output_object) — Dilated regions.
- **GolayElement** (input_control) — Structuring element from the Golay alphabet.
  - Default value: 'h'
  - List of values: GolayElement ∈ {'l', 'd', 'c', 'f', 'h', 'k'}
- **Iterations** (input_control) — Number of iterations.
  - Default value: 1
  - Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
  - Typical range of values: 1 ≤ Iterations (lin)
  - Minimum increment: 1
  - Recommended increment: 1

Complexity

Let $F$ be the area of an input region. Then the runtime complexity for one region is:

$$O(\text{Iterations} \cdot 20 \cdot \sqrt{F}) .$$

Result

dilation_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  - set_system(‘no_object_result’,<RegionResult>)
- empty region:
  - set_system(‘empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Foundation

erosion_golay ( Region : RegionErosion : GolayElement, Iterations, Rotation : )

Erode a region with an element from the Golay alphabet.

erosion_golay is obsolete and is only provided for reasons of backward compatibility.

erosion_golay erodes a region with the selected element GolayElement from the Golay alphabet. The following structuring elements are available:

'1', 'm', 'd', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number Rotation determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements. The operator works by shifting the structuring element over the region to be processed (Region). For all positions of the structuring element fully contained in the region, the corresponding reference point (relative to the structuring element) is added to the output region. This means that the intersection of all translations of the structuring element within the region is computed.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \).

Attention

Not all values of Rotation are valid for any Golay element. For some of the values of Rotation, the resulting regions are identical to the input regions.

Parameters

▷ Region (input object) .......................................................... region(-array) \( \rightarrow \) object
Regions to be eroded.

▷ RegionErosion (output object) .......................................... region(-array) \( \rightarrow \) object
Eroded regions.

▷ GolayElement (input control) ......................................... string \( \rightarrow \) string
Structuring element from the Golay alphabet.
Default value: 'h'
List of values: GolayElement \( \in \) \{'1', 'm', 'd', 'e', 'i', 'f', 'f2', 'h', 'k'\}

▷ Iterations (input control) ................................................. integer \( \rightarrow \) integer
Number of iterations.
Default value: 1
Suggested values: Iterations \( \in \) \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
Typical range of values: \( 1 \leq \text{Iterations (lin)} \)
Minimum increment: 1
Recommended increment: 1

▷ Rotation (input control) ..................................................... integer \( \rightarrow \) integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default value: 0
List of values: Rotation \( \in \) \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}
**Complexity**

Let $F$ be the area of an input region. Then the runtime complexity for one region is:

$$O(3 \cdot \sqrt{F})$$

**Result**

`erosion_golay` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result', <RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result', <RegionResult>)
  ```

Otherwise, an exception is raised.

**Module**

**erosion_seq** ( Region : RegionErosion : GolayElement, Iterations : )

Erode a region sequentially.

`erosion_seq` is obsolete and is only provided for reasons of backward compatibility.

`erosion_seq` computes the sequential erosion of the input region `Region` with the selected structuring element `GolayElement` from the Golay alphabet. This is done by executing the operator `erosion_golay` with all rotations of the structuring element `Iterations` times. The following structuring elements can be selected: 'l', 'd', 'c', 'f', 'h', 'k'.

Only the “foreground elements” (even rotation numbers) are used. The elements 'i' and 'e' result in unchanged output regions. The elements 'l', 'm' and 'f2' are identical for the foreground. The Golay elements, together with all possible rotations, are described with the operator `golay_elements`.

**Parameters**

- **Region** (input_object) : object
  Regions to be eroded.
- **RegionErosion** (output_object) : object
  Eroded regions.
- **GolayElement** (input_control) : string
  Structuring element from the Golay alphabet.

  **Default value**: 'h'

  **List of values**: `GolayElement ∈ {'l', 'd', 'c', 'f', 'h', 'k'}`
Iterations (input_control) ................................. integer  \sim  integer

Number of iterations.

Default value: 1

Suggested values: Iterations \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 20, 30, 40, 50\}

Typical range of values: 1 \leq \text{Iterations (lin)}

Minimum increment: 1

Recommended increment: 1

\begin{align*}
\text{fitting} ( \text{Region, StructElements : RegionFitted : : } )
\end{align*}

Perform a closing after an opening with multiple structuring elements.

\textbf{fitting} is obsolete and is only provided for reasons of backward compatibility.

\textbf{fitting} performs an \textbf{opening} and a \textbf{closing} successively on the input regions. The eight structuring elements normally used for this operation can be generated with the operator \textbf{gen\_struct\_elements}. However, other user-defined structuring elements can also be used. Let \( R \) be the input region(s) and let \( M_i \) denote the structuring elements. Furthermore, let \( P \) be the result of the opening and \( Q \) be the final result. Then the operator can be formalized as follows:

\begin{align*}
P &= \bigcup_{i=1}^{n} (R \circ M_i) \\
Q &= \bigcap_{i=1}^{n} (P \bullet M_i)
\end{align*}
Regions larger than the structuring elements are preserved, while small gaps are closed.

### Parameters

- **Region** (input_object) \(\rightarrow\) region\((-\text{array})\) \(\rightarrow\) object
  
  Regions to be processed.

- **StructElements** (input_object) \(\rightarrow\) region\((-\text{array})\) \(\rightarrow\) object
  
  Structuring elements.

- **RegionFitted** (output_object) \(\rightarrow\) region\((-\text{array})\) \(\rightarrow\) object
  
  Fitted regions.

### Result

fitting returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  ```
  set_system('no_object_result', <RegionResult>)
  ```

- empty region:
  
  ```
  set_system('empty_region_result', <RegionResult>)
  ```

Otherwise, an exception is raised.

---

**gen_struct_elements** ( : StructElements : Type, Row, Column : )

Generate standard structuring elements.

**gen_struct_elements** is obsolete and is only provided for reasons of backward compatibility.

**gen_struct_elements** serves to generate eight structuring elements normally used in the operator fitting. The default value **'noise'** of the parameter **Type** generates elements especially suited for the elimination of noise.
CHAPTER 17 LEGACY

Parameters

- **StructElements** (output_object) .................................................. region(-array) ∼ object
  Generated structuring elements.

- **Type** (input_control) ................................................................. string ∼ string
  Type of structuring element to generate.
  Default value: 'noise'
  List of values: Type ∈ {'noise'}

- **Row** (input_control) ................................................................. point.y ∼ integer
  Row coordinate of the reference point.
  Default value: 1
  Suggested values: Row ∈ {0, 1, 10, 50, 100, 200, 300, 400}

- **Column** (input_control) ............................................................. point.x ∼ integer
  Column coordinate of the reference point.
  Default value: 1
  Suggested values: Column ∈ {0, 1, 10, 50, 100, 200, 300, 400}

Result

gen_struct_elements returns 2 (H_MSG_TRUE) if all parameters are correct. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

golay_elements

Module

Foundation

golay_elements ( : StructElement1, StructElement2 : GolayElement,
Rotation, Row, Column : )

Generate the structuring elements of the Golay alphabet.

golay_elements is obsolete and is only provided for reasons of backward compatibility.

golay_elements generates the structuring elements from the Golay alphabet. The parameter GolayElement determines the name of the structuring element, while Rotation determines its rotation. The structuring elements are intended for use in hit_or_miss: In StructElement1 the structuring element for the foreground is returned, while in StructElement2 the structuring element for the background is returned. Row and Column determine the reference point of the structuring element.

The rotations are numbered from 0 to 15. This does not mean, however, that there are 16 different rotations: Even values denote rotations of the foreground elements, while odd values denote rotations of the background elements.

For golay_elements only even values are accepted, and determine the Golay element for StructElement1. The next larger odd value is used for StructElement2. There are no rotations for the Golay elements ’h’ and ’i’. Therefore, only the values 0 and 1 are possible as “rotations” (and hence only 0 for golay_elements). The element ’e’ has only four possible rotations, and hence the rotation must be between 0 and 7 (for golay_elements the values 0, 2, 4, or 6 must be used).

The tables below show the elements of the Golay alphabet with all possible rotations. The characters used have the following meaning:

- Foreground pixel
o Background pixel
• Don’t care pixel

The names of the elements and their rotation numbers are displayed below the respective element. The elements with even number contain the foreground pixels, while the elements with odd numbers contain the background pixels.
Parameters

- StructElement1 (output_object) required region \( \leadsto \) object
  Structuring element for the foreground.
- StructElement2 (output_object) required region \( \leadsto \) object
  Structuring element for the background.
GoGolayElement (input_control) string ~ string
Name of the structuring element.
Default value: 'l'
List of values: GolayElement ∈ {'t', 'm', 'd', 'e', 'i', 'f', 'f2', 'h', 'k'}

Rotation (input_control) integer ~ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default value: 0
List of values: Rotation ∈ {0, 2, 4, 6, 8, 10, 12, 14}

Row (input_control) point.y ~ integer
Row coordinate of the reference point.
Default value: 16
Suggested values: Row ∈ {0, 16, 32, 128, 256}
Typical range of values: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Column (input_control) point.x ~ integer
Column coordinate of the reference point.
Default value: 16
Suggested values: Column ∈ {0, 16, 32, 128, 256}
Typical range of values: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Result

It should be noted that the input parameters are processed without parallelization.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

hit_or_miss

Alternatives

gen_region_points, gen_struct_elements, gen_region_polygon_filled

References

Module

Foundation

Hit-or-miss operation for regions using the Golay alphabet.

hit_or_miss_golay is obsolete and is only provided for reasons of backward compatibility.

hit_or_miss_golay performs the hit-or-miss-transformation for the input regions Region (using structuring elements from the Golay alphabet). First, an erosion with the foreground of the structuring element GolayElement is done on the input region Region. Then an erosion with the background of the structuring element GolayElement is performed on the complement of the input region. The intersection of the two resulting regions is the result RegionHitMiss of hit_or_miss_golay. The following structuring elements are available:
The rotation number \texttt{Rotation} determines which rotation of the element should be used. The hit-or-miss-transformation selects precisely the points for which the conditions given by the selected Golay element are fulfilled.

\textbf{Attention}

Not all values of \texttt{Rotation} are valid for any Golay element.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{Region} (input\_object) \quad region(-array) \sim object
    Regions to be processed.
  \item \texttt{RegionHitMiss} (output\_object) \quad region(-array) \sim object
    Result of the hit-or-miss operation.
  \item \texttt{GolayElement} (input\_control) \quad string
    Structuring element from the Golay alphabet.
    \textbf{Default value:} 'h'
    \textbf{List of values:} \texttt{GolayElement} \in \{'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'\}
  \item \texttt{Rotation} (input\_control) \quad integer
    Rotation of the Golay element. Depending on the element, not all rotations are valid.
    \textbf{Default value:} 0
    \textbf{List of values:} \texttt{Rotation} \in \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}
\end{itemize}

\textbf{Complexity}

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \, . \]

\textbf{Result}

hit\_or\_miss\_golay returns 2 (H\_MSG\_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

\begin{itemize}
  \item no region:
    \texttt{set\_system(‘no\_object\_result’,<RegionResult>)}
  \item empty region:
    \texttt{set\_system(‘empty\_region\_result’,<RegionResult>)}
\end{itemize}

Otherwise, an exception is raised.

\textbf{Parallelization}

\begin{itemize}
  \item Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  \item Multithreading scope: global (may be called from any thread).
  \item Automatically parallelized on tuple level.
\end{itemize}

\textbf{Possible Predecessors}

\begin{itemize}
  \item threshold, region\_growing, connection, union\_1, watersheds, class\_ndim\_norm
\end{itemize}

\textbf{Possible Successors}

\begin{itemize}
  \item reduce\_domain, select\_shape, area\_center, connection
\end{itemize}

\textbf{Alternatives}

hit\_or\_miss\_seg, hit\_or\_miss

**hit_or_miss_seq** ( Region : RegionHitMiss : GolayElement : )

**Hit-or-miss operation for regions using the Golay alphabet (sequential).**

**hit_or_miss_seq** is obsolete and is only provided for reasons of backward compatibility.

**hit_or_miss_golay** performs the hit-or-miss-transformation for the input regions Region using all rotations of a structuring element from the Golay alphabet. The result of the operator is the union of all intermediate results of the respective rotations. The following structuring elements are available:

'1', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The Golay elements, together with all possible rotations, are described with the operator **golay_elements**.

---

**Parameters**

- **Region** (input_object) region(-array) → object
  Regions to be processed.
- **RegionHitMiss** (output_object) region(-array) → object
  Result of the hit-or-miss operation.
- **GolayElement** (input_control) string → string
  Structuring element from the Golay alphabet.
  Default value: 'h'
  List of values: GolayElement ∈ {'1', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

---

**Complexity**

Let $F$ be the area of an input region, and $R$ be the number of rotations. Then the runtime complexity for one region is:

$$O(R \cdot 6 \cdot \sqrt{F})$$

---

**Result**

**hit_or_miss_seq** returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:**
  set_system('no_object_result',<RegionResult>)
- **empty region:**
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Predecessors**

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

**Possible Successors**

reduce_domain, select_shape, area_center, connection

**Alternatives**

hit_or_miss_golay, hit_or_miss

**See also**

thinning_seq, thickening_seq

---

**Module**

Foundation
morph_hat ( Region, StructElement : RegionMorphHat : : )

Compute the union of bottom_hat and top_hat.

morph_hat is obsolete and is only provided for reasons of backward compatibility.
morph_hat computes the union of the regions that are removed by an opening operation with the regions that are added by a closing operation. Hence this is the union of the results of top_hat and bottom_hat. The position of StructElement does not influence the result.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Attention

The individual regions are processed separately.

Parameters

- Region (input_object) .................................................. region(-array) ⇒ object
  Regions to be processed.
- StructElement (input_object) ........................................... region ⇒ object
  Structuring element (position-invariant).
- RegionMorphHat (output_object) ....................................... region(-array) ⇒ object
  Union of top hat and bottom hat.

Example

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
    cout << "Reproduction of 'dilation_circle ()'" << endl;
    cout << "First = original image " << endl;
    cout << "Red = after segmentation " << endl;
    cout << "Blue = after erosion " << endl;

    HByteImage img("monkey");
    HWindow w;

    HRegion circ = HRegion::GenCircle (10, 10, 1.5);
    HRegionArray regs = (img >= 128).Connection();
    HRegionArray tophat = regs.TopHat (circ);
    HRegionArray bothat = regs.BottomHat (circ);
    HRegionArray unionX = tophat.Union2 (bothat);

    img.Display (w); w.Click ();
    w.SetColor ("red"); reg.Display (w); w.Click ();
    w.SetColor ("blue"); tophat.Display (w); w.Click ();
    w.SetColor ("green"); bothat.Display (w); w.Click ();
    w.SetColor ("white"); unionX.Display (w); w.Click ();

    return(0);
}
```

Result

morph_hat returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors
threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

Possible Successors
reduce_domain, select_shape, area_center, connection

Alternatives
top_hat, bottom_hat, union2

Module

morph_skeleton ( Region : RegionSkeleton : : )

Compute the morphological skeleton of a region.
morph_skeleton is obsolete and is only provided for reasons of backward compatibility.
morph_skeleton computes the skeleton of the input regions (Region) using morphological transformations. The computation yields a disconnected skeleton (gaps in the diagonals) having a width of one or two pixels. The calculation uses the Golay element ‘h’, i.e., an 8-neighborhood. This is equivalent to the maximum-norm.

Parameters

▷ Region (input_object) .................................................. region(-array) \rightarrow object
 Regions to be processed.
▷ RegionSkeleton (output_object) .................................. region(-array) \rightarrow object
 Resulting morphological skeleton.

Result

morph_skeleton returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

• no region:
  set_system(‘no_object_result’,<RegionResult>)
• empty region:
  set_system(‘empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.
• Automatically parallelized on tuple level.

**Module**

Foundation

---

**morph_skiz** ( Region : RegionSkiz : Iterations1, Iterations2 : )

**Thinning of a region.**

**morph_skiz** is obsolete and is only provided for reasons of backward compatibility.

**morph_skiz** first performs a sequential thinning (**thinning_seq**) of the input region with the element ‘l’ of the Golay alphabet. The number of iterations is determined by the parameter **Iterations1**. Then a sequential thinning of the resulting region with the element ‘e’ of the Golay alphabet is carried out. The number of iterations for this step is determined by the parameter **Iterations2**. The skiz operation serves to compute a kind of skeleton of the input regions, and to prune the branches of the resulting skeleton. If the skiz operation is applied to the complement of the region, the region and the resulting skeleton are separated.

If very large values or ‘maximal’ are passed for **Iterations1** or **Iterations2**, the processing stops if no more changes occur.

---

**Parameters**

- **Region** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . region(-array)  \( \rightsquigarrow \) object
  Regions to be thinned.

- **RegionSkiz** (output_object) . . . . . . . . . . . . . . . . . . . region(-array)  \( \rightsquigarrow \) object
  Result of the skiz operator.

- **Iterations1** (input_control) . . . . . . . . . . . . . . . . . . . . integer  \( \rightsquigarrow \) integer / string
  Number of iterations for the sequential thinning with the element ‘l’ of the Golay alphabet.
  **Default value:** 100
  **Suggested values:** Iterations1 \( \in \) \{'maximal’, 0, 1, 2, 3, 5, 7, 10, 15, 20, 30, 40, 50, 70, 100, 150, 200, 300, 400\}
  **Typical range of values:** 0 \( \leq \) Iterations1 (lin)
  **Minimum increment:** 1
  **Recommended increment:** 1

- **Iterations2** (input_control) . . . . . . . . . . . . . . . . . . . . integer  \( \rightsquigarrow \) integer / string
  Number of iterations for the sequential thinning with the element ‘e’ of the Golay alphabet.
  **Default value:** 1
  **Suggested values:** Iterations2 \( \in \) \{'maximal’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
  **Typical range of values:** 0 \( \leq \) Iterations2 (lin)
  **Minimum increment:** 1
  **Recommended increment:** 1

---

**Complexity**

Let \( F \) be the area of the input region. Then the runtime complexity for one region is

\[ O((\text{Iterations1} + \text{Iterations2}) \cdot 3 \cdot \sqrt{F}) \] .

---

**Result**

**morph_skiz** returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system(’no_object_result’,<RegionResult>)
  ```

• empty region:
  
  ```cpp
  set_system('empty_region_result',<RegionResult>)
  ```

  Otherwise, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Predecessors**

---

**Possible Successors**

- pruning, reduce_domain, select_shape, area_center, connection, background_seg, complement

---

**Alternatives**

- skeleton, thinning_seq, morph_skeleton, interjacent

---

**See also**

- thinning, hit_or_miss_seq, difference

---

**Module**

**opening_golay** ( Region : RegionOpening : GolayElement, Rotation : )

Open a region with an element from the Golay alphabet.

**opening_golay** is obsolete and is only provided for reasons of backward compatibility.

**opening_golay** is defined as a Minkowski subtraction followed by a Minkowski addition. First the Minkowski subtraction of the input region (Region) with the structuring element from the Golay alphabet defined by **GolayElement** and **Rotation** is computed. Then the Minkowski addition of the result and the structuring element rotated by 180° is performed.

The following structuring elements are available:

- 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number **Rotation** determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator **golay_elements**.

**opening_golay** serves to eliminate regions smaller than the structuring element, and to smooth regions’ boundaries.

---

**Attention**

Not all values of **Rotation** are valid for any Golay element. For some of the values of **Rotation**, the resulting regions are identical to the input regions.

---

**Parameters**

- **Region** (input_object) : region(-array) ~ object
  Regions to be opened.

- **RegionOpening** (output_object) : region(-array) ~ object
  Opened regions.

- **GolayElement** (input_control) : string ~ string
  Structuring element from the Golay alphabet.

  **Default value**: 'h'

  **List of values**: GolayElement ∈ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
\*\* Rotation \*\* (input_control) .................................................. \* integer \* \* integer \* Rotation of the Golay element. Depending on the element, not all rotations are valid.

Default value: \* 0 \* List of values: Rotation \* ∈ \* \{ 0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15 \* \}

### Complexity

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[
O(6 \cdot \sqrt{F})
\]

### Result

opening_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

### Possible Successors

reduce_domain, select_shape, area_center, connection

### Alternatives

opening_seg, opening

### Module

**opening_seg** ( Region, StructElement : RegionOpening : : )

Separate overlapping regions.

opening_seg is obsolete and is only provided for reasons of backward compatibility.

The opening_seg operation is defined as a sequence of the following operators: erosion1, connection and dilation1 (see example). Only one iteration is done in erosion1 and dilation1.

opening_seg serves to separate overlapping regions whose area of overlap is smaller than StructElement. It should be noted that the resulting regions can overlap without actually merging (see expand_region).

opening_seg uses the center of gravity as the reference point of the structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.
17.9. MORPHOLOGY

Parameters

- Region (input_object) ........................................... region(-array)  \(\rightarrow\) object
  Regions to be opened.
- StructElement (input_object) .................................. region  \(\rightarrow\) object
  Structuring element (position-invariant).
- RegionOpening (output_object) ................................ region-array  \(\rightarrow\) object
  Opened regions.

Example

* Simulation of opening_seg
  opening_seg(Region, StructElement, RegionOpening):
    erosion1(Region, StructElement, H1, 1)
    connection(H1, H2)
    dilation1(H2, StructElement, RegionOpening, 1)

Complexity

Let \(F_1\) be the area of the input region, and \(F_2\) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \sqrt[3]{\sqrt{F_1}}).
\]

Result

opening_seg returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  \texttt{set_system(’no\_object\_result’,<RegionResult>)}
- empty region:
  \texttt{set_system(’empty\_region\_result’,<RegionResult>)}

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

Possible Successors

expand_region, reduce_domain, select_shape, area_center, connection

Alternatives

erosion1, connection, dilation1

Module

\textbf{thickening ( Region, StructElement1, StructElement2 : RegionThick : Row, Column, Iterations : )}

Add the result of a hit-or-miss operation to a region.
thickening is obsolete and is only provided for reasons of backward compatibility.

thickening performs a thickening of the input regions using morphological operations. The operator first applies a hit-or-miss-transformation to Region (cf. hit_or_miss), and then adds the detected points to the input region. The parameter Iterations determines the number of iterations performed.

For the choice of the structuring elements StructElement1 and StructElement2, as well as for Row and Column, the same restrictions described under hit_or_miss apply.

The structuring elements (StructElement1 and StructElement2) can be generated by calling golay_elements, for example.

> Region (input_object) .......................................................... region(-array)  \( \sim \) object

Regions to be processed.

> StructElement1 (input_object) .............................................. region  \( \sim \) object

Structuring element for the foreground.

> StructElement2 (input_object) .............................................. region  \( \sim \) object

Structuring element for the background.

> RegionThick (output_object) .................................................. region(-array)  \( \sim \) object

Result of the thickening operator.

> Row (input_control) ............................................................. point.y  \( \sim \) integer

Row coordinate of the reference point.

Default value: 16
Suggested values: \( \text{Row} \in \{0, 2, 4, 8, 16, 32, 128\} \)
Typical range of values: \( 0 \leq \text{Row} \leq 511 \) (lin)
Minimum increment: 1
Recommended increment: 1

> Column (input_control) ........................................................ point.x  \( \sim \) integer

Column coordinate of the reference point.

Default value: 16
Suggested values: \( \text{Column} \in \{0, 2, 4, 8, 16, 32, 128\} \)
Typical range of values: \( 0 \leq \text{Column} \leq 511 \) (lin)
Minimum increment: 1
Recommended increment: 1

> Iterations (input_control) ..................................................... integer  \( \sim \) integer

Number of iterations.

Default value: 1
Suggested values: \( \text{Iterations} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50, 70, 100, 200, 400\} \)
Typical range of values: \( 1 \leq \text{Iterations} \) (lin)
Minimum increment: 1
Recommended increment: 1

Let \( F \) be the area of an input region, \( F_1 \) the area of the structuring element 1, and \( F_2 \) the area of the structuring element 2. Then the runtime complexity for one object is:

\[
O\left(\text{Iterations} \cdot \sqrt{F} \cdot \left(\sqrt{F_1} + \sqrt{F_2}\right)\right).
\]

thickening returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```c
  set_system('no_object_result',<RegionResult>)
  ```

- empty region:
  ```c
  set_system('empty_region_result',<RegionResult>)
  ```
Otherwise, an exception is raised.

---

**Parallelization**

thickening_golay ( Region : RegionThick : GolayElement,
Rotation : )

---

*Add the result of a hit-or-miss operation to a region (using a Golay structuring element).*

**thickening_golay** is obsolete and is only provided for reasons of backward compatibility.

thickening_golay performs a thickening of the input regions using morphological operations and structuring elements from the Golay alphabet. The operator first applies a hit-or-miss-transformation to *Region* (cf. *hit_or_miss_golay*), and then adds the detected points to the input region. The following structuring elements are available:

- 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number *Rotation* determines which rotation of the element should be used. The Golay elements, together with all possible rotations, are described with the operator *golay_elements*.

---

**Attention**

Not all values of *Rotation* are valid for any Golay element.

---

**Parameters**

<table>
<thead>
<tr>
<th>Region (input_object)</th>
<th>region(-array) ~ object</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegionThick (output_object)</td>
<td>region(-array) ~ object</td>
</tr>
<tr>
<td>GolayElement (input_control)</td>
<td>string ~ string</td>
</tr>
<tr>
<td>Rotation (input_control)</td>
<td>integer ~ integer</td>
</tr>
</tbody>
</table>

---

**Default value**: 0

**List of values**: Rotation ∈ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

---

**Complexity**

Let *F* be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \]
thickening_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  \[\text{set_system('no_object_result',<RegionResult>)}\]
- empty region:
  \[\text{set_system('empty_region_result',<RegionResult>)}\]

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

thickening, thickening_seq

See also

erosion_golay, hit_or_miss_golay

Module

Foundation

thickening_seq ( Region : RegionThick : GolayElement, Iterations : )

Add the result of a hit-or-miss operation to a region (sequential).

thickening_seq is obsolete and is only provided for reasons of backward compatibility.

thickening_seq calculates the sequential thickening of the input regions with a structuring element from the Golay alphabet (GolayElement). To do so, thickening_seq calls the operator thickening_golay with all possible rotations of the structuring element \(\text{Iterations}\) times. The following structuring elements are available:

- 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The Golay elements, together with all possible rotations, are described with the operator golay_elements. For all elements of the Golay alphabet, except for 'c', the foreground and background masks are exchanged in order to have an effect for them on the outer boundary of the region. The element 'c' can be used to generate the convex hull of the input region if enough iterations are performed.

Parameters

▶ Region (input_object) .................................................. region(-array) ~ object
  Regions to be processed.
▶ RegionThick (output_object) ........................................ region(-array) ~ object
  Result of the thickening operator.
▶ GolayElement (input_control) ...................................... string ~ string
  Structuring element from the Golay alphabet.
  Default value: 'h'
  List of values: GolayElement ∈ \{'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'\}
▶ Iterations (input_control) .......................................... integer ~ integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50, 70, 100, 200\}
  Typical range of values: 1 ≤ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1
17.9. MORPHOLOGY

Complexity

Let $F$ be the area of an input region. Then the runtime complexity for one region is:

\[ O(\text{Iterations} \cdot 6 \cdot \sqrt{F}) \ . \]

Result

thickening_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

thickening_golay, thickening

See also

erosion_golay, thinning_seq

Module

thinning

Remove the result of a hit-or-miss operation from a region.

thinning is obsolete and is only provided for reasons of backward compatibility.

thinning performs a thinning of the input regions using morphological operations. The operator first applies a hit-or-miss-transformation to Region (cf. hit_or_miss), and then removes the detected points from the input region. The parameter Iterations determines the number of iterations performed.

For the choice of the structuring elements StructElement1 and StructElement2, as well as for Row and Column, the same restrictions described under hit_or_miss apply.

Structuring elements (StructElement1, StructElement2) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- **Region** (input_object) .................................................. region(-array) \(\rightsquigarrow\) object
  Regions to be processed.
- **StructElement1** (input_object) ................................... region \(\rightsquigarrow\) object
  Structuring element for the foreground.
- **StructElement2** (input_object) ................................... region \(\rightsquigarrow\) object
  Structuring element for the background.
- **RegionThin** (output_object) ....................................... region(-array) \(\rightsquigarrow\) object
  Result of the thinning operator.
**Row** (input_control) ................................................................. point.y $\sim$ integer
Row coordinate of the reference point.
**Default value:** 0
**Typical range of values:** $0 \leq \text{Row} \leq 511$ (lin)
**Minimum increment:** 1
**Recommended increment:** 1

**Column** (input_control) ................................................................. point.x $\sim$ integer
Column coordinate of the reference point.
**Default value:** 0
**Typical range of values:** $0 \leq \text{Column} \leq 511$ (lin)
**Minimum increment:** 1
**Recommended increment:** 1

**Iterations** (input_control) ................................................................. integer $\sim$ integer
Number of iterations.
**Default value:** 1
**Suggested values:** $\text{Iterations} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}$
**Typical range of values:** $1 \leq \text{Iterations}$ (lin)
**Minimum increment:** 1
**Recommended increment:** 1

---

**Complexity**

Let $F$ be the area of an input region, $F_1$ the area of the structuring element 1, and $F_2$ the area of the structuring element 2. Then the runtime complexity for one object is:

$$O\left(\text{Iterations} \cdot \sqrt{F} \cdot \left(\sqrt{F_1} + \sqrt{F_2}\right)\right).$$

---

**Result**

thinning returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

**Module**

Foundation

thinning_golay  { Region : RegionThin : GolayElement, Rotation : )

Remove the result of a hit-or-miss operation from a region (using a Golay structuring element).

thinning_golay is obsolete and is only provided for reasons of backward compatibility.

thinning_golay performs a thinning of the input regions using morphological operations and structuring elements from the Golay alphabet. The operator first applies a hit-or-miss-transformation to Region (cf. hit_or_miss_golay), and then removes the detected points from the input region. The following structuring elements are available:

'1', 'm', 'd', 'c', 'e', 'i', 't', 'f2', 'h', 'k'.

The rotation number Rotation determines which rotation of the element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

Attention

Not all values of Rotation are valid for any Golay element.

Parameters

▷ Region (input_object) .................................................. region(-array) ~ object
Regions to be processed.
▷ RegionThin (output_object) ....................................... region(-array) ~ object
Result of the thinning operator.
▷ GolayElement (input_control) ........................................ string ~ string
Structuring element from the Golay alphabet.
  Default value: 'h'
  List of values: GolayElement ∈ {'1', 'm', 'd', 'c', 'e', 'i', 't', 'f2', 'h', 'k'}
▷ Rotation (input_control) ............................................ integer ~ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
  Default value: 0
  List of values: Rotation ∈ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \] .

Result

thinning_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

• no region:
  set_system(’no_object_result’,<RegionResult>)
• empty region:
  set_system(’empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Successors

reduce_domain, select_shape, area_center, connection

HALCON 20.05.0.0
thinning_seq ( Region : RegionThin : GolayElement, Iterations : )

Remove the result of a hit-or-miss operation from a region (sequential).

thinning_seq is obsolete and is only provided for reasons of backward compatibility.

thinning_seq calculates the sequential thinning of the input regions with a structuring element from the Golay alphabet (GolayElement). To do so, thinning_seq calls the operator thinning_golay with all possible rotations of the structuring element Iterations times. If Iterations is chosen large enough, the operator calculates the skeleton of a region if the structuring elements 'l' or 'm' are used. For the element 'c' the background and foreground are exchanged in order to have an effect on the interior boundary of a region. If a very large value or 'maximal' is passed for Iterations the iteration stops if no more changes occur. The following structuring elements are available:

'l'  Skeleton, similar to skeleton. This structuring element is also used in morph_skiz.
'm'  A skeleton with many “hairs” and multiple (parallel) branches.
'd'  A skeleton without multiple branches, but with many gaps, similar to morph_skeleton.
'c'  Uniform erosion of the region.
'e'  One pixel wide lines are shortened. This structuring element is also used in morph_skiz.
'f'  Y-junctions are eliminated. (Only Iterations = 1 is useful.)
'h'  A kind of inner boundary, which, however, is thicker than the result of boundary, is generated. (Only Iterations = 1 is useful.)
'k'  Junction points are eliminated, but also new ones are generated.

The Golay elements, together with all possible rotations, are described with the operator golay_elements.

Parameters

- **Region** (input_object)  region(-array)  ~ object
  Regions to be processed.
- **RegionThin** (output_object)  region(-array)  ~ object
  Result of the thinning operator.
- **GolayElement** (input_control)  string  ~ string
  Structuring element from the Golay alphabet.
  Default value: 'l'
  List of values: GolayElement ∈ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- **Iterations** (input_control)  integer / string  ~ integer / string
  Number of iterations. For 'f', 'f2', 'h' and 'i' the only useful value is 1.
  Default value: 20
  Suggested values: Iterations ∈ {'maximal', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 40, 50, 70, 100, 150, 200}
  Typical range of values: 1 ≤ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

\[ O(\text{Iterations} \cdot 6 \cdot \sqrt{F}) \] .

Result

thinning_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  set_system('no_object_result',<RegionResult>)
• empty region:
  
  set_system(‘empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

17.10 OCR

close_ocr ( : : OcrHandle : )

Deallocation of the memory of an OCR classifier.
close_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should
use the MLP, SVM or CNN based operators instead.

The operator close_ocr deallocates the memory of the classifier having the number OcrHandle. Hereby
all corresponding data will be deleted. However, if necessary, they can be saved in advance using the operator
write_ocr. The number OcrHandle will be invalid after the call; but later the system can use it again for new
classifiers.

Attention

All data of the classifier will be deleted in main memory (not on the hard disk).

Parameters

▷ OcrHandle (input_control) ...................................................... ocr_box ↦ handle
  ID of the OCR classifier to be deleted.

Result

If the parameter OcrHandle is valid, the operator close_ocr returns the value 2 (H_MSG_TRUE). Otherwise
an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• OcrHandle
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

write_ocr_trainf

Possible Successors

read_ocr

Module

OCR/OCV

| create_ocr_class_box ( : WidthPattern, HeightPattern, Interpolation, Features, Character : OcrHandle ) |

Create a new OCR-classifier.

create_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator create_ocr_class_box creates a new OCR classifier. For a description of this classifier see operator learn_class_box. This classifier must then be trained with the help of the operators traind_ocr_class_box or trainf_ocr_class_box.

The parameters WidthPattern and HeightPattern indicate the size of the input-layer of the network. This size is used for the features 'projection_horizontal', 'projection_vertical', 'pixel', 'pixel_invar', and 'pixel_binary' to transform the character to a standard size. The bigger the standard size is, the more characters can be distinguished. Hereby the amount of time necessary for the training (as well as the number of training random samples) and the time necessary for the recognition, however, will increase as well. The parameter Interpolation indicates the interpolation mode concerning the adaptation of characters in the image to the network. For more detailed information on this parameter see also affine_trans_image. The value 0 results in the same interpolation as 'nearest_neighbor' in affine_trans_image, i.e., no interpolation is performed. For 1, the same behavior as 'constant' in affine_trans_image is obtained, i.e., equally weighted interpolation between adjacent pixels is used. Finally, 2 results in the same interpolation as 'weighted', i.e., Gaussian interpolation between adjacent pixels is used. The parameter Interpolation must be chosen such that no aliasing occurs when the character is scaled to the standard size. Typically, this means that Interpolation should be set to 1, except in cases where the characters are scaled down by a large amount, in which case Interpolation = 2 should be chosen. Interpolation = 0 should only be chosen if the characters will not be scaled.

The parameter Character determines all the characters which have to be recognized. Normally the transmitted strings consist of one character (e.g. alphabet). But also strings of any length can be learned. The number of distinguishable characters (number of strings in Character) is limited to 2048.

The parameter Features helps to chose additional features besides gray values in order to recognize characters. The following features are available:

'default' 'ratio' and 'pixel_invar' are selected.

'ratio' Ratio of the character.

'width' Width of the character (not invariant to scaling).

'height' Height of the character (not invariant to scaling).

'zoom_factor' Difference in size between the current character and the values of WidthPattern and HeightPattern (not invariant to scaling).

'foreground' Relative number of pixels in the foreground.

'foreground_grid_9' Relative number of foreground pixels in a 3 x 3 grid within the surrounding rectangle of the character.

'foreground_grid_16' Relative number of foreground pixels in a 4 x 4 grid within the surrounding rectangle of the character.

'anisometry' Form feature anisometry.

'compactness' Form feature compactness.

'convexity' Form feature convexity.
'moments_region_2nd_invar' Normed 2nd geometric moments of the region. See also 'moments_region_2nd_invar'.

'moments_region_2nd_rel_invar' Normed 2nd relativ geometric moments of the region. See also 'moments_region_2nd_rel_invar'.

'moments_region_3rd_invar' Normed 3rd geometric moments of the region. See also 'moments_region_3rd_invar'.

'moments_central' Normed central geometric moments of the region. See also 'moments_region_central'.

'phi' Sinus and cosinus of the orientation (angle) of the character.

'num_connect' Number of connecting components.

'num_holes' Number of holes.

'projection_horizontal' Horizontal projection of the gray values.

'projection_horizontal_invar' Horizontal projection of the gray values with are automatically scaled to maximum range.

'projection_vertical' Vertical projection of the gray values.

'projection_vertical_invar' Vertical projection of the gray values with are automatically scaled to maximum range.

'cooc' Values of the binary cooccurrence matrix.

'moments_gray_plane' Normed gray value moments and the angles of the gray value level.

'num_runs' Number of chords in the region normed to the height.

'chord_histo' Frequency of the chords per row (not scale-invariant).

'pixel' Gray value of the character.

'pixel_invar' Gray values of the character with automatic maximal scaling of the gray values.

'pixel_binary' Region of the character as a binary image zoomed to a size of WidthPattern × HeightPattern.

'gradient_8dir' Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5 × 5 grid are extracted from each channel. These samples are used as features.

Parameters

▷ WidthPattern (input_control) ................................................. integer ~ integer
   Width of the input layer of the network.
   Default value: 8
   Suggested values: WidthPattern ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
   Typical range of values: 1 ≤ WidthPattern ≤ 100

▷ HeightPattern (input_control) ............................................. integer ~ integer
   Height of the input layer of the network.
   Default value: 10
   Suggested values: HeightPattern ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
   Typical range of values: 1 ≤ HeightPattern ≤ 100

▷ Interpolation (input_control) .............................................. integer ~ integer
   Interpolation mode concerning scaling of characters.
   Default value: 1
   List of values: Interpolation ∈ {0, 1, 2}

▷ Features (input_control) ................................................. string(-array) ~ string
   Additional features.
   Default value: 'default'
   List of values: Features ∈ {'default', 'zoom_factor', 'ratio', 'width', 'height', 'foreground',
   'foreground_grid_9', 'foreground_grid_16', 'anisometry', 'compactness', 'convexity',
   'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar',
   'moments_central', 'phi', 'num_connect', 'num_holes', 'projection_horizontal', 'projection_vertical',
   'projection_horizontal_invar', 'projection_vertical_invar', 'chord_histo', 'num_runs', 'pixel', 'pixel_invar',
   'pixel_binary', 'gradient_8dir', 'cooc', 'moments_gray_plane'}
CHAPTER 17 LEGACY

- **Character** (input_control) .......................... string-array ↝ string
  All characters of a set.
  **Default value:** ['a', 'b', 'c']

- **OcrHandle** (output_control) .......................... ocr_box ↝ handle
  ID of the created OCR classifier.

---

**Result**

If the parameters are correct, the operator `create_ocr_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```plaintext
deserialize_ocr ( : : SerializedItemHandle : OcrHandle )
```

Deserializes a serialized OCR classifier.

`deserialize_ocr` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

`deserialize_ocr` deserializes an OCR classifier, that was serialized by `serialize_ocr` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCR classifier with the handle `OcrHandle`.

**Parameters**

- `SerializedItemHandle` (input_control) `serialized_item` handle Handle of the serialized item.
- `OcrHandle` (output_control) `ocr_box` handle ID of the OCR classifier.

**Result**

If the parameters are valid, the operator `deserialize_ocr` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

```plaintext
do_ocr_multi ( Character, Image : : OcrHandle : Class, Confidence )
```

Classify characters.

`do_ocr_multi` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `do_ocr_multi` assigns a class to every `Character` (character). For gray value features the gray values from the surrounding rectangles of the regions are used. The gray values will be taken from the parameter `Image`. For each character the corresponding class will be returned in `Class` and a confidence value will be returned in `Confidence`. The confidence value indicates the similarity between the input pattern and the assigned character.
Parameters

- **Character** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . region(-array) \(\sim\) object
  Characters to be recognized.

- **Image** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . singlechannelimage \(\sim\) object : byte / uint2
  Gray values for the characters.

- **OcrHandle** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ocr_box \(\sim\) handle
  ID of the OCR classifier.

- **Class** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string(-array) \(\sim\) string
  Class (name) of the characters.
  **Number of elements:** Class == Character

- **Confidence** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real(-array) \(\sim\) real
  Confidence values of the characters.
  **Number of elements:** Confidence == Character

Result

If the input parameters are correct, the operator `do_ocr_single` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**do_ocr_single** ( Character, Image : : OcrHandle : : Classes,
Confidences )

Classify one character.

`do_ocr_single` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `do_ocr_single` assigns classes to the **Character** (characters). For gray value features gray values of the surrounding rectangles of the regions will be used. The gray values will be taken from the parameter **Image**. For each character the two classes with the highest confidences will be returned in **Classes**. The corresponding confidences will be returned in **Confidences**. The confidence value indicates the similarity between the input pattern and the assigned character.

Parameters

- **Character** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . region \(\sim\) object
  Character to be recognized.

- **Image** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . singlechannelimage \(\sim\) object : byte / uint2
  Gray values of the characters.

- **OcrHandle** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ocr_box \(\sim\) handle
  ID of the OCR classifier.

- **Classes** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string-array \(\sim\) string
  Classes (names) of the characters.
  **Number of elements:** 2

Confidences (output_control) ........................................ real-array \leadsto real

Number of elements: 2

Result

If the input parameters are correct, the operator do_ocr_single returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Get information about an OCR classifier.

info_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator info_ocr_class_box returns some information about an OCR classifier. The parameters are equivalent to those of create_ocr_class_box. The parameters WidthMaxChar and HeightMaxChar indicate the extension of the largest trained character. These values can be used to control the segmentation.

Parameters

• OcrHandle (input_control) ........................................ ocr_box \leadsto handle
  ID of the OCR classifier.
• WidthPattern (output_control) ........................................ integer \leadsto integer
  Width of the scaled characters.
• HeightPattern (output_control) ........................................ integer \leadsto integer
  Height of the scaled characters.
• Interpolation (output_control) ........................................ integer \leadsto integer
  Interpolation mode for scaling the characters.
• WidthMaxChar (output_control) ........................................ integer \leadsto integer
  Width of the largest trained character.
• HeightMaxChar (output_control) ........................................ integer \leadsto integer
  Height of the largest trained character.
• Features (output_control) ........................................ string-array \leadsto string
  Used features.
• Characters (output_control) ........................................ string-array \leadsto string
  All characters of the set.

Result

The operator info_ocr_class_box always returns 2 (H_MSG_TRUE).

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

```
read_ocr, create_ocr_class_box
```

```
write_ocr
```

**Possible Predecessors**

**Possible Successors**

Module

**OCR/OCV**

```
ocr_change_char ( : : OcrHandle, Character : )
```

Define a new conversion table for the characters.

**ocr_change_char** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator **ocr_change_char** establishes a new look-up table for the characters. Hereby the number of strings of **Character** must be the same as of the classifier **OcrHandle**. In order to enlarge the font, the operator **ocr_change_char** may be used as follows: More characters than actually needed will be indicated when creating a network using (create_ocr_class_box). The last \( n \) characters will not be used so far. If more characters are needed at a later stage, these unused characters will be allocated and then trained with the help of the operator **ocr_change_char**.

```
Parameters

\[ \text{OcrHandle} \text{ (input_control) \quad \text{ocr_box} \sim \text{handle} } \]
\[ \text{ID of the OCR-network to be changed.} \]

\[ \text{Character} \text{ (input_control) \quad \text{string-array} \sim \text{string} } \]
\[ \text{New assign of characters.} \]
\[ \text{Default value: } \{ 'a', 'b', 'c' \} \]
```

**Result**

If the number of characters in **Character** is identical with the number of the characters of the network, the operator **ocr_change_char** returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

**Parallelization**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• **OcrHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

**Possible Successors**

Module

**OCR/OCV**
**ocr_get_features** ( Character : : OcrHandle : FeatureVector )

Access the features which correspond to a character.

**ocr_get_features** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator **ocr_get_features** calculates the features for the given **Character**. The type and number of features is determined by the classifier **OcrHandle**. **FeatureVector** contains the same values which are used inside operators like **traind_ocr_class_box** or **trainf_ocr_class_box**.

---

**Parameters**

- **Character** (input_object) singlechannelimage; object : byte / uint2
  Characters to be trained.
- **OcrHandle** (input_control) ocr_box; handle
  ID of the desired OCR-classifier.
- **FeatureVector** (output_control) real-array; real
  Feature vector.

---

**Result**

If the parameters are correct, the operator **ocr_get_features** returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Possible Predecessors**

---

See also **trainf_ocr_class_box, traind_ocr_class_box**

---

**Module**

OCR/OCV

---

**read_ocr** ( : : FileName : OcrHandle )

Read an OCR classifier from a file.

**read_ocr** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator **read_ocr** reads an OCR classifier from a file **FileName**. This file will hereby be searched in the directory ($HALCONROOT/ocr/) as well as in the currently used directory. If too many classifiers have been loaded, an error message will be displayed.

---

**Parameters**

- **FileName** (input_control) filename.read; string
  Name of the OCR classifier file.
  Default value: 'testnet'
  File extension: .obc, .fnt
- **OcrHandle** (output_control) ocr_box; handle
  ID of the read OCR classifier.

---

**Result**

If the indicated file is available and the format is correct, the operator **read_ocr** returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

**Parallelization**

HALCON 20.05.0.0
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

write_ocr, do_ocr_multi, traind_ocr_class_box, trainf_ocr_class_box

Module

OCR/OCV

```
serialize_ocr ( : : OcrHandle : SerializedItemHandle )
```

Serialize an OCR classifier.

`serialize_ocr` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

`serialize_ocr` serializes an OCR classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ocr` is converted to a serialized item. The OCR classifier is defined by the handle `OcrHandle`. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr`.

Parameters

- **OcrHandle** (input_control) ➔ `ocr_box` ➔ handle ID of the OCR classifier.
- **SerializedItemHandle** (output_control) ➔ `serialized_item` ➔ handle Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

```
testd_ocr_class_box ( Character, Image : : OcrHandle, 
                    Class : Confidence )
```

Test an OCR classifier.

testd_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator testd_ocr_class_box tests the confidence with which a character belongs to a given class. Any number of regions of an image can be passed. For each character (region) in Character the corresponding name (class) Class must be specified. The gray values are passed in Image. When the operator has finished the parameter Confidence provides information about how sure a character belongs to the (arbitrary chosen) class.

Parameters

- **Character** (input_object) region(-array) → object Characters to be tested.
- **Image** (input_object) singlechannelimage → object : byte / uint2 Gray values for the characters.
- **OcrHandle** (input_control) ocr_box → handle ID of the desired OCR-classifier.
- **Class** (input_control) string(-array) → string Class (name) of the characters.
  Default value: 'a'
- **Confidence** (output_control) real(-array) → real Confidence for the character to belong to the class.

Result

If the parameters are correct, the operator testd_ocr_class_box returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_ocr, trainf_ocr_class_box, traind_ocr_class_box

Module

OCR/OCV

traind_ocr_class_box ( Character, Image : : OcrHandle, Class : : AvgConfidence )

Train an OCR classifier by the input of regions.

traind_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator traind_ocr_class_box trains the classifier directly via the input of regions in an image. Any number of regions of an image can be passed. For each character (region) in Character the corresponding name (class) Class must be specified. The gray values are passed in Image. When the procedure has finished the parameter AvgConfidence provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly).

Parameters

- **Character** (input_object) region(-array) → object Characters to be trained.
- **Image** (input_object) singlechannelimage → object : byte / uint2 Gray values for the characters.
- **OcrHandle** (input_control) ocr_box → handle ID of the desired OCR-classifier.
CHAPTER 17 LEGACY

◮ **Class** (input_control) .............................................................. string(-array) ˜ string
   Class (name) of the characters.
   Default value: ’a’
◮ **AvgConfidence** (output_control) ............................................... real ˜ real
   Average confidence during a re-classification of the trained characters.

If the parameters are correct, the operator `traind_ocr_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

◮ **Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:
- OcrHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

◮ **Possible Predecessors**
  - `create_ocr_class_box, read_ocr`

◮ **Possible Successors**
  - `write_ocr, do_ocr_multi, do_ocr_single`

◮ **Alternatives**
  - `trainf_ocr_class_box`

◮ **Module**
  - OCR/OCV

```
trainf_ocr_class_box ( : : OcrHandle,
                       TrainingFile : AvgConfidence )
```

*Train an OCR classifier with the help of a training file.*

`trainf_ocr_class_box` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `trainf_ocr_class_box` trains the classifier `OcrHandle` via the indicated training files. Any number of files can be indicated. The parameter `AvgConfidence` provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly). Please, note that training characters that have no corresponding class in the classifier `OcrHandle` are discarded.

◮ **Attention**

The names of the characters in the file must fit the network.

◮ **Parameters**

◮ **OcrHandle** (input_control) ....................................................... ocr_box ˜ handle
   ID of the desired OCR-network.
◮ **TrainingFile** (input_control) .................................................. filename.read(-array) ˜ string
   Names of the training files.
   Default value: ‘train_ocr’
   File extension: .trf, .otr
◮ **AvgConfidence** (output_control) .............................................. real ˜ real
   Average confidence during a re-classification of the trained characters.
If the file name is correct and the data fit the network, the operator `trainf_ocr_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `OcrHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

- `create_ocr_class_box, read_ocr`

**Alternatives**

- `traind_ocr_class_box`

**Module**

OCR/OCV

---

**write_ocr** ( : : OcrHandle, FileName : )

*Writing an OCR classifier into a file.*

`write_ocr` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `write_ocr` writes the OCR classifier `OcrHandle` into the file `FileName`. Since the data of the classifier will be lost when the program is finished, they have to be stored after the training if the user wants to use them again at a later execution of the program. The data can then be read with the help of the operator `read_ocr`. The extension will be added automatically to the parameter `FileName`.

**Attention**

The output file `FileName` must be given without extension.

**Parameters**

- **OcrHandle** (input_control) : ocr_box ~ handle
  ID of the OCR classifier.
- **FileName** (input_control) : filename.write ~ string
  Name of the file for the OCR classifier (without extension).

**Default value:** `my_ocr`

**File extension:** `.obc`

**Result**

If the parameter `OcrHandle` is valid and the indicated file can be written, the operator `write_ocr` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
### 17.11 Regions

**get_region_chain** ( Region : : : Row, Column, Chain )

Contour of an object as chain code.

**get_region_chain** is obsolete and is only provided for reasons of backward compatibility.

The operator `get_region_chain` returns the contour of a region. A contour is a series of pixels describing the outline of the region. The contour "lies on" the region. It starts at the smallest line number; in that line at the pixel with the largest column index. The rotation occurs clockwise. Holes of the region are ignored. The direction code (chain code) is defined as follows:

\[
\begin{array}{cccc}
3 & 2 & 1 & \\
4 & \ast & 0 & \\
5 & 6 & 7 & \\
\end{array}
\]

The operator `get_region_chain` returns the code in the form of a tuple. In case of an empty region the parameters `Row` and `Column` are zero and `Chain` is the empty tuple.

Attention

Holes of the region are ignored. Only one region may be passed, and it must have exactly one connection component.

**Parameters**

- **Region** (input_object) : region \(\rightsquigarrow\) object
  - Region to be transformed.
- **Row** (output_control) : chain.begin.y \(\rightsquigarrow\) integer
  - Line of starting point.
- **Column** (output_control) : chain.begin.x \(\rightsquigarrow\) integer
  - Column of starting point.
- **Chain** (output_control) : chain.code-array \(\rightsquigarrow\) integer
  - Direction code of the contour (from starting point).

**Typical range of values:** \(0 \leq \text{Chain} \leq 7\)

**Result**

The operator `get_region_chain` normally returns the value 2 (H_MSG_TRUE). If more than one connection component is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via the operator `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module
Foundation

```
hamming_change_region ( InputRegion : OutputRegion : Width, Height, 
                        Distance : )
```

Generate a region having a given Hamming distance.

**hamming_change_region** is obsolete and is only provided for reasons of backward compatibility.

**hamming_change_region** changes the region in the left upper part of the image given by **Width** and **Height** such that the resulting regions have a Hamming distance of **Distance** to the input regions. This is done by adding or removing **Distance** points from the input region.

**Attention**
If **Width** and **Height** are chosen too large the resulting region requires a lot of memory.

**Parameters**

- **InputRegion** (input_object) ......................... region(-array)  \( \sim \) object
  Region to be modified.

- **OutputRegion** (output_object) ...................... region(-array)  \( \sim \) object
  Regions having the required Hamming distance.

- **Width** (input_control) ................................. extent.x  \( \sim \) integer
  Width of the region to be changed.
  Default value: 100
  Suggested values: \( \text{Width} \in \{64, 128, 256, 512\} \)
  Typical range of values: \( 1 \leq \text{Width} \leq 512 \) (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: \( \text{Width} > 0 \)

- **Height** (input_control) ................................. extent.y  \( \sim \) integer
  Height of the region to be changed.
  Default value: 100
  Suggested values: \( \text{Height} \in \{64, 128, 256, 512\} \)
  Typical range of values: \( 1 \leq \text{Height} \leq 512 \) (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: \( \text{Height} > 0 \)

- **Distance** (input_control) ............................ integer  \( \sim \) integer
  Hamming distance between the old and new regions.
  Default value: 1000
  Suggested values: \( \text{Distance} \in \{100, 500, 1000, 5000, 10000\} \)
  Typical range of values: \( 0 \leq \text{Distance} \leq 10000 \) (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: \( \text{Distance} \geq 0 \) \&\& \( \text{Distance} < \text{Width} \times \text{Height} \)

**Complexity**
Memory requirement of the generated region (worst case): \( O(2 \times \text{Width} \times \text{Height}) \).

**Result**
hamming_change_region returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system(’no_object_result’,<Result>)`. If necessary, an exception is raised.
Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- hamming_distance

Module

interjacent (Region : RegionInterjacent : Mode : )

Partition the image plane using given regions.

interjacent is obsolete and is only provided for reasons of backward compatibility.

interjacent partitions the image plane using the regions given in Region. The result is a region containing the extracted separating lines. The following modes of operation can be used:

- **'medial_axis'** This mode is used for regions that do not touch or overlap. The operator will find separating lines between the regions which partition the background evenly between the input regions. This corresponds to the following calls:
  
  complement('full',Region,Tmp)
  skeleton(Tmp,Result)

- **'border'** If the input regions do not touch or overlap this mode is equivalent to boundary(Region,Result), i.e., it replaces each region by its boundary. If regions are touching they are aggregated into one region. The corresponding output region then contains the boundary of the aggregated region, as well as the one pixel wide separating line between the original regions. This corresponds to the following calls:
  
  boundary(Region,Tmp1,'inner')
  union1(Tmp1,Tmp2)
  skeleton(Tmp2,Result)

- **'mixed'** In this mode the operator behaves like the mode 'medial_axis' for non-overlapping regions. If regions touch or overlap, again separating lines between the input regions are generated on output, but this time including the “touching line” between regions, i.e., touching regions are separated by a line in the output region. This corresponds to the following calls:
  
  erosion1(Region,Mask,Tmp1,1)
  union1(Tmp1,Tmp2)
  complement(full,Tmp2,Tmp3)
  skeleton(Tmp3,Result)

where Mask denotes the following “cross mask”:

```
×
× × ×
×
```
17.12. SEGMENTATION

Parameters

▶ Region (input_object) .......................................................... region(-array) → object
  Regions for which the separating lines are to be determined.
▶ RegionInterjacent (output_object) .................................. region → object
  Output region containing the separating lines.
▶ Mode (input_control) ......................................................... string → string
  Mode of operation.
  Default value: 'mixed'
  List of values: Mode ∈ ['medial_axis', 'border', 'mixed']

Example

read_image(Image,'forest_air1')
mean_image(Image,Mean,31,31)
dyn_threshold(Image,Mean,Seg,20,'light')
interjacent(Seg,Graph,'medial_axis')
dev_display(Graph)

Result

interjacent always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region','true'/'false'). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

threshold,connection,regiongrowing,pouring

Possible Successors

select_shape,disp_region

See also

expand_region, junctions_skeleton, boundary

Module

17.12 Segmentation

**bin_threshold** ( Image : Region : : )

Segment an image using an automatically determined threshold.

**bin_threshold** is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **binary_threshold** instead.

**bin_threshold** segments a single-channel gray value image using an automatically determined threshold. First, the relative histogram of the gray values is determined. Then, relevant minima are extracted from the histogram, which are used as parameters for a thresholding operation. In order to reduce the number of minima, the histogram is smoothed with a Gaussian, as in **auto_threshold**. The mask size is enlarged until there is only one minimum in the smoothed histogram. The selected region contains the pixels with gray values from 0 to the minimum or for real images from the smallest value to the respective minimum. This operator is, for example useful for the segmentation of dark characters on a light paper.
Parameters

- **Image** (input_object) ........................................... singlechannelimage(-array) \(\sim\) object : byte / uint2 / real
  Input image.
- **Region** (output_object) .................................................. region(-array) \(\sim\) object
  Dark regions of the image.

Example

```haskell
read_image (Image, 'letters')
bin_threshold (Image, Seg)
connection (Seg, Connected)
```

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module

```haskell
class_ndim_box ( MultiChannelImage : Regions : ClassifHandle : )
```

Classify pixels using hyper-cuboids.

class_ndim_box is obsolete and is only provided for reasons of backward compatibility.

class_ndim_box classifies the pixels of the multi-channel image given in MultiChannelImage. To do so, the classifier ClassifHandle created with create_class_box is used. The classifier can be trained using learn_ndim_box or as described with create_class_box. More information on the structure of the classifier can be found also under that operator.

MultiChannelImage is a multi channel image. Its pixel values are used for the classification.

Example

```haskell
read_image(Image,'montery')
dev_display(Image)
dev_set_color('green')
disp_message (WindowHandle, 'Draw learning region ',\
  'window', 12, 12, 'black', 'true')
draw_region(Reg1,WindowHandle)
reduce_domain(Image,Reg1,Foreground)
dev_set_color('red')
disp_message (WindowHandle, 'Draw background region',\
  'window', 12, 12, 'black', 'true')
draw_region(Reg2,WindowHandle)
```
reduce_domain(Image,Reg2,Background)
disp_message (WindowHandle, 'Training... ',
   'window', 12, 12, 'black', 'true')
create_class_box(ClassifHandle)
learn_ndim_box(Foreground,Background,Image,ClassifHandle)
disp_message (WindowHandle, 'Classification ',
   'window', 12, 12, 'black', 'true')
class_ndim_box(Image,Res,ClassifHandle)
dev_set_draw('fill')
dev_display (Res)
close_class_box(ClassifHandle)

Complexity
Let \( N \) be the number of hyper-cuboids and \( A \) be the area of the input region. Then the runtime complexity is \( O(N,A) \).

Result
class_ndim_box returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags 'no_object_result', 'empty_region_result', and 'store_empty_region' with set_system. If necessary, an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
create_class_box, learn_class_box, median_image, compose2, compose3, compose4, compose5, compose6, compose7

Alternatives
class_ndim_norm, class_2dim_sup, class_2dim_unsup

See also
descript_class_box

Module

expand_line ( Image : RegionExpand : Coordinate, ExpandType, RowColumn, Threshold : )

Expand a region starting at a given line.

expand_line is obsolete and is only provided for reasons of backward compatibility.

expand_line generates a region by expansion, starting at a given line (row or column). The expansion is terminated when the current gray value differs by more than Threshold from the mean gray value along the line (ExpandType = 'mean') or from the previously added gray value (ExpandType = 'gradient').

Parameters

Image (input_object) ......................... singlechannelimage(-array) \( \sim \) object : byte
   Input image.
RegionExpand (output_object) .................. region(-array) \( \sim \) object
   Extracted segments.
Coordinate (input_control) .................... integer \( \sim \) integer
   Row or column coordinate.
Default value: 256
Suggested values: Coordinate \( \in \) \{ 16, 64, 128, 200, 256, 300, 400, 511 \}
Restriction: Coordinate \( \geq 0 \)
ExpandType (input_control) string → string
Stopping criterion.
Default value: 'gradient'
List of values: ExpandType ∈ ['gradient', 'mean']

RowColumn (input_control) string → string
Segmentation mode (row or column).
Default value: 'row'
List of values: RowColumn ∈ ['row', 'column']

Threshold (input_control) number → real / integer
Threshold for the expansion.
Default value: 3.0
Suggested values: Threshold ∈ [0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 13.0, 17.0, 20.0, 30.0]
Typical range of values: 1.0 ≤ Threshold ≤ 255.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0
Restriction: Threshold >= 0.0 && Threshold <= 255.0

Example
---

```c++
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[]) {
    HImage image (argv[1]),
    gauss;
    HWindow win;

    win.SetDraw ("margin");
    win.SetColored (12);
    image.Display (win);
    
    gauss = image.GaussImage (5);
    
    HRegionArray reg = gauss.ExpandLine (100, "mean", "row", 5.0);
    reg.Display (win);
    win.Click ();
    
    return (0);
}
```

Parallelization
---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Alternatives
regionGrowing_mean, expand_gray, expand_gray_ref

Module

learn_ndim_box ( Foreground, Background,
                 MultiChannelImage : : ClassifHandle : )

Train a classifier using a multi-channel image.

learn_ndim_box trains the classifier ClassifHandle with the gray values of MultiChannelImage using the points in Foreground as training sample. The points in Background are to be rejected by the classifier. The classifier trained thus can be used in class_ndim_box to segment multi-channel images. Foreground are the points that should be found, Background contains the points that should not be found.

Each pixel is trained once during the training process. For points in Foreground the class “0” is used, while for Background “1” is used. Pixels are trained by alternating points from Foreground with points from Background. If one region is smaller than the other, pixels are taken cyclically from the smaller region until the larger region is exhausted. learn_ndim_box later accepts only points that can be classified into class “0”.

From a user’s point of view the key difference between learn_ndim_norm and learn_ndim_box is that in the latter case the rejection class affects the classification process itself. Here, a hyper plane is generated that separates Foreground and Background classes, so that no points in feature space are classified incorrectly. As for learn_ndim_norm, however, an overlap between Foreground and Background class is allowed. This has its effect on the return value Quality. The larger the overlap, the smaller this value.

Attention
All channels must be of the same type.

Parameters

- Foreground (input_object) region(-array) object
  Foreground pixels to be trained.
- Background (input_object) region(-array) object
  Background pixels to be trained (rejection class).
- MultiChannelImage (input_object) (multichannel-)image(-array) object : byte / direction / cyclic / int1 / int2 / int4 / real
  Multi-channel training image.
- ClassifHandle (input_control) class_box handle
  Handle of the classifier.

Complexity

Let $N$ be the number of generated hyper-cuboids and $\hat{A}$ be the area of the larger input region. Then the runtime complexity is $O(N \times \hat{A})$.

Result

learn_ndim_box returns 2 (H_MSG_TRUE) if all parameters are correct and there is an active classifier. The behavior with respect to the input images can be determined by setting the values of the flags 'no_object_result' and 'empty_region_result' with set_system. If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

HALCON 20.05.0.0
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

17.13 Tools

approx_chain ( : : Row, Column, MinWidthCoord, MaxWidthCoord, ThreshStart, ThreshEnd, ThreshStep, MinWidthSmooth, MaxWidthSmooth, MinWidthCurve, MaxWidthCurve, Weight1, Weight2, Weight3 : ArcCenterRow, ArcCenterCol, ArcAngle, ArcBeginRow, ArcBeginCol, LineBeginRow, LineBeginCol, LineEndRow, LineEndCol, Order )

Approximate a contour by arcs and lines.

approx_chain is obsolete and is only provided for reasons of backward compatibility.

The coordinates of a curve are approximated by a row of lines and arcs. The procedure tries values from a user-definable range for certain parameters. The limits of these ranges are explicitly stated in the parameter list of the function (MinWidthCoord ... MaxWidthCoord, ThreshStart ... ThreshEnd, MinWidthSmooth ... MaxWidthSmooth, MinWidthCurve ... MaxWidthCurve). Additionally, the step width for the parameter area of the threshold value for pointed corners has to be indicated (ThreshStep). By narrowing the covered areas the runtime of the calculation can be shortened, but the result may deteriorate.

The parameters Weight1, Weight2 and Weight3 indicate whether the desired weighting is placed more on precision of the approximation, obtaining as much large segments as possible or as few small segments as possible. Thus, for (Weight1,Weight2,Weight3) (1,0,0) creates a very precise approximation and (0,1,1) an approximation with as few large segments as possible.

The result of the procedure is returned separately as arcs and lines. If one is interested in the sequence of the segments the individual resulting elements can be read successively from the resulting tuples; the sequence can be taken from the return parameter order (0: next element is next line segment, 1: next element is next arc segment).

Attention

Contours which can possibly consist of only one segment should also be examined with a threshold maximum (ThreshEnd) > 1.0, because otherwise at least one “corner point” is determined in any case.

Parameters

- **Row** (input_control) : point.y-array ▼ integer
  Row of the contour.
  Default value: 32

- **Column** (input_control) : point.x-array ▼ integer
  Column of the contour.
  Default value: 32

- **MinWidthCoord** (input_control) : real ▼ real
  Minimum width of Gauss operator for coordinate smoothing (> 0.4).
  Default value: 0.5
  Suggested values: MinWidthCoord ∈ {0.5, 0.7, 1.0, 1.2, 1.5, 1.7}
  Typical range of values: 0.4 ≤ MinWidthCoord ≤ 3.0 (lin)
  Minimum increment: 0.01
  Recommended increment: 0.1
MaxWidthCoord (input_control) ................................. real \rightarrow real
Maximum width of Gauss operator for coordinate smoothing (> 0.4).
Default value: 2.4
Suggested values: MaxWidthCoord \in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}
Typical range of values: 0.4 \leq \text{MaxWidthCoord} \leq 3.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

ThreshStart (input_control) ................................. real \rightarrow real
Minimum threshold value of the curvature for accepting a corner (relative to the largest curvature present).
Default value: 0.3
Suggested values: ThreshStart \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8\}
Typical range of values: 0.1 \leq \text{ThreshStart} \leq 0.9 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

ThreshEnd (input_control) ................................. real \rightarrow real
Maximum threshold value of the curvature for accepting a corner (relative to the largest curvature present).
Default value: 0.9
Suggested values: ThreshEnd \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8\}
Typical range of values: 0.1 \leq \text{ThreshEnd} \leq 0.9 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

ThreshStep (input_control) ................................. real \rightarrow real
Step width for threshold increase.
Default value: 0.2
Suggested values: ThreshStep \in \{0.3, 0.4, 0.5\}
Typical range of values: 0.1 \leq \text{ThreshStep} \leq 0.9 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

MinWidthSmooth (input_control) ................................. real \rightarrow real
Minimum width of Gauss operator for smoothing the curvature function (> 0.4).
Default value: 0.5
Suggested values: MinWidthSmooth \in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}
Typical range of values: 0.4 \leq \text{MinWidthSmooth} \leq 3.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

MaxWidthSmooth (input_control) ................................. real \rightarrow real
Maximum width of Gauss operator for smoothing the curvature function.
Default value: 2.4
Suggested values: MaxWidthSmooth \in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}
Typical range of values: 0.4 \leq \text{MaxWidthSmooth} \leq 3.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

MinWidthCurve (input_control) ................................. integer \rightarrow integer
Minimum width of curve area for curvature determination (> 0.4).
Default value: 2
Suggested values: MinWidthCurve \in \{2, 5, 7\}
Typical range of values: 1 \leq \text{MinWidthCurve} \leq 12 (lin)
Minimum increment: 1
Recommended increment: 2

MaxWidthCurve (input_control) ................................. integer \rightarrow integer
Maximum width of curve area for curvature determination.
Default value: 12
Suggested values: MaxWidthCurve \in \{2, 5, 7\}
Typical range of values: 1 \leq \text{MaxWidthCurve} \leq 20 (lin)
Minimum increment: 1
Recommended increment: 2
Weight1 (input_control) ................................................................. real $\sim$ real
Weighting factor for approximation precision.
Default value: 1.0
Suggested values: $Weight1 \in \{0.0, 0.5, 1.0\}$
Typical range of values: $0.0 \leq Weight1 \leq 1.0$ (lin)
Minimum increment: 0.1
Recommended increment: 0.5

Weight2 (input_control) ................................................................. real $\sim$ real
Weighting factor for large segments.
Default value: 1.0
Suggested values: $Weight2 \in \{0.0, 0.5, 1.0\}$
Typical range of values: $0.0 \leq Weight2 \leq 1.0$ (lin)
Minimum increment: 0.1
Recommended increment: 0.5

Weight3 (input_control) ................................................................. real $\sim$ real
Weighting factor for small segments.
Default value: 1.0
Suggested values: $Weight3 \in \{0.0, 0.5, 1.0\}$
Typical range of values: $0.0 \leq Weight3 \leq 1.0$ (lin)
Minimum increment: 0.1
Recommended increment: 0.5

ArcCenterRow (output_control) ................................................. arc.center.y-array $\sim$ integer
Row of the center of an arc.

ArcCenterCol (output_control) ...................................................... arc.center.x-array $\sim$ integer
Column of the center of an arc.

ArcAngle (output_control) .......................................................... arc.angle.rad-array $\sim$ real
Angle of an arc.

ArcBeginRow (output_control) ..................................................... arc.begin.y-array $\sim$ integer
Row of the starting point of an arc.

ArcBeginCol (output_control) ...................................................... arc.begin.x-array $\sim$ integer
Column of the starting point of an arc.

LineBeginRow (output_control) .................................................... line.begin.y-array $\sim$ integer
Row of the starting point of a line segment.

LineBeginCol (output_control) ...................................................... line.begin.x-array $\sim$ integer
Column of the starting point of a line segment.

LineEndRow (output_control) ...................................................... line.end.y-array $\sim$ integer
Row of the ending point of a line segment.

LineEndCol (output_control) ...................................................... line.end.x-array $\sim$ integer
Column of the ending point of a line segment.

Order (output_control) ............................................................ integer-array $\sim$ integer
Sequence of line (value 0) and arc segments (value 1).

Example

/* read edge image */
read_image(&Image,"fig1_kan");
/* construct edge region */
hysteresis_threshold(Image,&RK1,64,255,40,1);
connection(RK1,&Rand);
/* fetch chain code */
T_get_region_contour(Rand,&Rows,&Columns);
firstline = get_i(Tline,0);
firstcol = get_i(Tcol,0);
/* approximation with lines and circular arcs */
set_d(t1,0.4,0);
set_d(t2,2.4,0);
set_d(t3,0.3,0);

```
set_d(t4,0.9,0);
set_d(t5,0.2,0);
set_d(t6,0.4,0);
set_d(t7,2.4,0);
set_i(t8,2,0);
set_i(t9,12,0);
set_d(t10,1.0,0);
set_d(t11,1.0,0);
set_d(t12,1.0,0);

T_approx_chain(Rows,Columns,t1,t2,t3,t4,t5,t6,t7,t8,t9,t10,t11,t12,
               &Bzl,&Bzc,&Br,&Bwl,&Bwc,&Ll0,&Lc0,&Ll1,&Lc1,&order);

nob = length_tuple(Bzl);
nol = length_tuple(Ll0);
/* draw lines and arcs */
set_i(WindowHandleTuple,WindowHandle,0);
set_line_width(WindowHandle,4);
if (nob>0) T_disp_arc(Bzl,Bzc,Br,Bwl,Bwc);
set_line_width(WindowHandle,1);
if (nol>0) T_disp_line(WindowHandleTuple,Ll0,Lc0,Ll1,Lc1);
```

---

**Result**

The operator `approx_chain` returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Possible Predecessors**

---

**See also**

- get_region_chain, smallest_circle, disp_circle, disp_line

---

**Module**

---

**approx_chain_simple**

```
approx_chain_simple ( : : Row, Column : ArcCenterRow,
                     ArcCenterCol, ArcAngle, ArcBeginRow, ArcBeginCol, LineBeginRow,
                     LineBeginCol, LineEndRow, LineEndCol, Order )
```

Approximate a contour by arcs and lines.

**approx_chain_simple** is obsolete and is only provided for reasons of backward compatibility.

The contour of a curve is approximated by a sequence of lines and arcs.

The result of the procedure is returned separately as arcs and lines. If one is interested in the sequence of the segments the individual resulting elements can be read successively from the resulting tuples. The sequence can be taken from the return parameter order (0: next element is next line segment, 1: next element is next arc segment).
The operator `approx_chain_simple` behaves similarly as `approx_chain` except that in the case of `approx_chain_simple` the missing parameters are internally allocated as follows: 

- `MinWidthCoord` = 1.0
- `MaxWidthCoord` = 3.0
- `ThreshStart` = 0.5
- `ThreshEnd` = 0.9
- `ThreshStep` = 0.3
- `MinWidthSmooth` = 1.0
- `MaxWidthSmooth` = 3.0
- `MinWidthCurve` = 2
- `MaxWidthCurve` = 9
- `Weight1` = 1.0
- `Weight2` = 1.0
- `Weight3` = 1.0

Parameters

- **Row** (input_control) .......................................................... point.y-array  \(\sim\) integer
  Row of the contour.
  Default value: 32

- **Column** (input_control) .................................................... point.x-array  \(\sim\) integer
  Column of the contour.
  Default value: 32

- **ArcCenterRow** (output_control) ........................................... arc.center.y-array  \(\sim\) integer
  Row of the center of an arc.

- **ArcCenterCol** (output_control) ......................................... arc.center.x-array  \(\sim\) integer
  Column of the center of an arc.

- **ArcAngle** (output_control) .............................................. arc.angle.rad-array  \(\sim\) real
  Angle of an arc.

- **ArcBeginRow** (output_control) .......................................... arc.begin.y-array  \(\sim\) integer
  Row of the starting point of an arc.

- **ArcBeginCol** (output_control) .......................................... arc.begin.x-array  \(\sim\) integer
  Column of the starting point of an arc.

- **LineBeginRow** (output_control) ........................................ line.begin.y-array  \(\sim\) integer
  Row of the starting point of a line segment.

- **LineBeginCol** (output_control) ........................................ line.begin.x-array  \(\sim\) integer
  Column of the starting point of a line segment.

- **LineEndRow** (output_control) .......................................... line.end.y-array  \(\sim\) integer
  Row of the ending point of a line segment.

- **LineEndCol** (output_control) .......................................... line.end.x-array  \(\sim\) integer
  Column of the ending point of a line segment.

- **Order** (output_control) .................................................. integer-array  \(\sim\) integer
  Sequence of line (value 0) and arc segments (value 1).

Example

```c
/* read edge image */
read_image(&Image,"fig1_kan");
/* construct edge region */
hysteresis_threshold(Image,&RK1,64,255,40,1);
connection(RK1,&Rand);
/* fetch chain code */
T_get_region_contour(Rand,&Rows,&Columns);
firstline = get_i(Tline,0);
firstcol = get_i(Tcol,0);
/* approximation with lines and circular arcs */
T_approx_chain_simple(Rows,Columns,
  &Bzl,&Bzc,&Br,&Bwl,&Bwc,&Ll0,&Lc0,&Ll1,&Lc1,&order);
 Nob = length_tuple(Bzl);
 Nol = length_tuple(Ll0);
/* draw lines and arcs */
set_i(WindowHandleTuple,WindowHandle,0);
set_line_width(WindowHandle,4);
if (nob>0) T_disp_arc(Bzl,Bzc,Br,Bwl,Bwc);
set_line_width(WindowHandle,1);
if (nol>0) T_disp_line(WindowHandleTuple,Ll0,Lc0,Ll1,Lc1);
```

Result

The operator `approx_chain_simple` returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.
Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

• Multithreading type: exclusive (runs in parallel only with independent operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

 clear_all_component_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all component models.
clear_all_component_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_component_models, the operator will be removed in future versions.

Attention

clear_all_component_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_component_models must not be used in any application.

Result
clear_all_component_models always returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

 clear_all_conditions ( : : : )

This operator is inoperable. It had the following function: Destroy all condition synchronization objects.
clear_all_conditions is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_framegrabbers, the operator will be removed in future versions.

Attention

clear_all_conditions exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_conditions must not be used in any application.

Result
clear_all_conditions returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: independent (runs in parallel even with exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
clear_all_data_code_2d_models ( : : : )

This operator is inoperable. It had the following function: Delete all 2D data code models and free the allocated memory.

clear_all_data_code_2d_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_data_code_2d_models, the operator will be removed in future versions.

Attention
clear_all_data_code_2d_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_data_code_2d_models must not be used in any application.

Result
The operator clear_all_data_code_2d_models returns the value 2 (H_MSG_TRUE) if all 2D data code models were freed correctly. Otherwise, an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
Data Code

clear_all_deformable_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all deformable models.

clear_all_deformable_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_deformable_models, the operator will be removed in future versions.

Attention
clear_all_deformable_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_deformable_models must not be used in any application.

Result
clear_all_deformable_models always returns 2 (H_MSG_TRUE).

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
Matching

clear_all_descriptor_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all descriptor models in RAM.

clear_all_descriptor_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_descriptor_models, the operator will be removed in future versions.
Result

If the operator is successful, clear_descriptor_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

clear_all_events ( : : : )

This operator is inoperable. It had the following function: Clear all event synchronization objects.
clear_all_events is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_events, the operator will be removed in future versions.

Attention

clear_all_events exists solely for the purpose of implementing the “reset program” functionality in HDdevelop. clear_all_events must not be used in any application.

Result

clear_all_events returns 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_all_lexica ( : : : )

This operator is inoperable. It had the following function: Clear all lexica.
clear_all_lexica is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_lexica, the operator will be removed in future versions.

Attention

clear_all_lexica exists solely for the purpose of implementing the “reset program” functionality in HDdevelop. clear_all_lexica must not be used in any application.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
### clear_all_matrices ( : : : )

This operator is inoperable. It had the following function: Clear all matrices from memory.

**clear_all_matrices** is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_matrices**, the operator will be removed in future versions.

**Attention**

**clear_all_matrices** exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_matrices** must not be used in any application.

**Result**

**clear_all_matrices** always returns the value 2 (H_MSG_TRUE).

**Parallelization**

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### clear_all_metrology_models ( : : : )

This operator is inoperable. It had the following function: Delete all metrology models and free the allocated memory.

**clear_all_metrology_models** is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_metrology_models**, the operator will be removed in future versions.

**Attention**

**clear_all_metrology_models** exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_metrology_models** must not be used in any application.

**Result**

The operator **clear_all_metrology_models** returns the value 2 (H_MSG_TRUE) if all metrology models were freed correctly. Otherwise, an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
clear_all_mutexes ( : : : )

This operator is inoperable. It had the following function: Clear all mutex synchronization objects.
clear_all_mutexes is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_mutexes, the operator will be removed in future versions.

Attention clear_all_mutexes exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_mutexes must not be used in any application.

Result clear_all_mutexes returns 2 (H_MSG_TRUE).

Parallelization
• Multithreading type: independent (runs in parallel even with exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module Foundation

clear_all_ncc_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all NCC models.
clear_all_ncc_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_ncc_models, the operator will be removed in future versions.

Attention clear_all_ncc_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_ncc_models must not be used in any application.

Result clear_all_ncc_models always returns 2 (H_MSG_TRUE).

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module Matching

clear_all_object_model_3d ( : : : )

This operator is inoperable. It had the following function: Free the memory of all 3D object models.
clear_all_object_model_3d is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_object_model_3d, the operator will be removed in future versions.
clear_all_object_model_3d exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_object_model_3d must not be used in any application.

Result

clear_all_object_model_3d always returns 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

clear_all_ocr_class_knn ( : : : )

This operator is inoperable. It had the following function: Clear all OCR classifiers.
clear_all_ocr_class_knn is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_ocr_class_knn, the operator will be removed in future versions.

Attention

clear_all_ocr_class_knn exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_ocr_class_knn must not be used in any application.

Result

clear_all_ocr_class_knn always returns 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

clear_all_ocr_class_mlp ( : : : )

This operator is inoperable. It had the following function: Clear all OCR classifiers.
clear_all_ocr_class_mlp is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_ocr_class_mlp, the operator will be removed in future versions.

Attention

clear_all_ocr_class_mlp exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_ocr_class_mlp must not be used in any application.

Result

clear_all_ocr_class_mlp always returns 2 (H_MSG_TRUE).
clear_all_ocr_class_svm ( : : : )

This operator is inoperable. It had the following function: Clear all SVM based OCR classifiers. clear_all_ocr_class_svm is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_ocr_class_svm, the operator will be removed in future versions.

Attention clear_all_ocr_class_svm exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_ocr_class_svm must not be used in any application.

Result clear_all_ocr_class_svm always returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module OCR/OCV

clear_all_sample_identifiers ( : : : )

This operator is inoperable. It had the following function: Free the memory of all sample identifiers. clear_all_sample_identifiers is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_sample_identifiers, the operator will be removed in future versions.

Attention clear_all_sample_identifiers exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_sample_identifiers must not be used in any application.

Result clear_all_sample_identifiers always returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module OCR/OCV

Matching
This operator is inoperable. It had the following function: Clear all scattered data interpolators.
clear_all_scattered_data_interpolators is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_scattered_data_interpolators, the operator will be removed in future versions.

Attention

clear_all_scattered_data_interpolators exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_scattered_data_interpolators must not be used in any application.

Result
clear_all_scattered_data_interpolators always returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
Foundation

This operator is inoperable. It had the following function: Delete all current existing serialized items.
clear_all_serialized_items is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_serialized_items, the operator will be removed in future versions.

Attention

clear_all_serialized_items exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_serialized_items must not be used in any application.

Result
If the parameters are valid, the operator clear_all_serialized_items returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

Attention clear_all_text_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_text_models must not be used in any application.

Result clear_all_text_models returns the value 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module OCR/OCV

clear_all_text_results ( : : : )

This operator is inoperable. It had the following function: Clear all text results. clear_all_text_results is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_text_results, the operator will be removed in future versions.

Attention clear_all_text_results exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_text_results must not be used in any application.

Result clear_all_text_results returns the value 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module Foundation

clear_all_training_components ( : : : )

This operator is inoperable. It had the following function: Free the memory of all component training results. clear_all_training_components is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_training_components, the operator will be removed in future versions.

Attention clear_all_training_components exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_training_components must not be used in any application.

Result clear_all_training_components always returns 2 (H_MSG_TRUE).

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

 clear_all_variation_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all variation models. clear_all_variation_models is obsolete, inoperable and is only provided for reasons of backward compatibility. New applications should not use clear_all_variation_models, the operator will be removed in future versions.

Attention

clear_all_variation_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_variation_models must not be used in any application.

Result

clear_all_variation_models always returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

 close_all_bg_esti ( : : : )

This operator is inoperable. It had the following function: Delete all background estimation data sets. close_all_bg_esti is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_bg_esti, the operator will be removed in future versions.

Attention

close_all_bg_esti exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_bg_esti must not be used in any application.

Result

If it is possible to close the background estimation data sets the operator close_all_bg_esti returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
**close_all_class_box ( : : : )**

This operator is inoperable. It had the following function: Destroy all classifiers.

`close_all_class_box` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `close_all_class_box`, the operator will be removed in future version.

Attention

`close_all_class_box` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `close_all_class_box` must not be used in any application.

**Result**

If it is possible to close the classifiers the operator `close_all_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Parallelization**

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

Foundation

---

**close_all_files ( : : : )**

This operator is inoperable. It had the following function: Close all open files.

`close_all_files` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `close_all_files`, the operator will be removed in future version.

Attention

`close_all_files` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `close_all_files` must not be used in any application.

**Result**

If it is possible to close the files the operator `close_all_files` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

Foundation

**close_all_framegrabbers ( : : : )**

This operator is inoperable. It had the following function: Close all image acquisition devices.

`close_all_framegrabbers` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `close_all_framegrabbers`, the operator will be removed in future versions.
Attention

close_all_framegrabbers exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_framegrabbers must not be used in any application.

For a multithreaded application all image acquisition operators (as listed in open_framegrabber) are an own group in which info_framegrabber, open_framegrabber, close_framegrabber and close_all_framegrabbers are executed exclusively.

Thus, info_framegrabber, open_framegrabber, close_framegrabber and close_all_framegrabbers block the concurrent execution of all other operators within this group, but run in parallel with all non-exclusive operators outside of this group.

Result

If it is possible to close all image acquisition devices, the operator close_all_framegrabbers returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

Foundation

close_all_measures ( : : : )

This operator is inoperable. It had the following function: Delete all measure objects.

close_all_measures is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_measures, the operator will be removed in future versions.

Attention

close_all_measures exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_measures must not be used in any application.

Result

close_all_measures always returns 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

1D Metrology

close_all_ocrs ( : : : )

This operator is inoperable. It had the following function: Destroy all OCR classifiers.

close_all_ocrs is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_ocrs, the operator will be removed in future versions.
Attention close_all_ocrs exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_ocrs must not be used in any application.

Result

If it is possible to close the OCR classifiers the operator close_all_ocrs returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

OCR/OCV

close_all_ocvs ( : : : )

This operator is inoperable. It had the following function: Clear all OCV tools.

close_all_ocvs is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_ocvs, the operator will be removed in future versions.

Attention close_all_ocvs exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_ocvs must not be used in any application.

Result

close_all_ocvs returns always 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

```plaintext
filter_kalman ( : : Dimension, Model, Measurement,
               PredictionIn : PredictionOut, Estimate )
```

Estimate the current state of a system with the help of the Kalman filtering.

`filter_kalman` is obsolete and is only provided for reasons of backward compatibility.

The operator `filter_kalman` returns an estimate of the current state (or also a prediction of a future state) of a discrete, stochastically disturbed, linear system. In practice, Kalman filters are used successfully in image processing in the analysis of image sequences (background identification, lane tracking with the help of line tracing or region analysis, etc.). A short introduction concerning the theory of the Kalman filters will be followed by a detailed description of the routine `filter_kalman` itself.

KALMAN FILTER: A discrete, stochastically disturbed, linear system is characterized by the following markers:

• State $x(t)$: Describes the current state of the system (speeds, temperatures,...).
• Parameter $u(t)$: Inputs from outside into the system.
• Measurement $y(t)$: Measurements gained by observing the system. They indicate the state of the system (or at least parts of it).
• An output function describing the dependence of the measurements on the state.
• A transition function indicating how the state changes with regard to time, the current value and the parameters.

The output function and the transition function are linear. Their application can therefore be written as a multiplication with a matrix.

The transition function is described with the help of the transition matrix $A(t)$ and the parameter matrix $G(t)$, the initial function is described by the measurement matrix $C(t)$. Hereby $C(t)$ characterizes the dependency of the new state on the old, $G(t)$ indicates the dependency on the parameters. In practice it is rarely possible (or at least too time consuming) to describe a real system and its behaviour in a complete and exact way. Normally only a relatively small number of variables will be used to simulate the behaviour of the system. This leads to an error, the so called system error (also called system disturbance) $v(t)$.

The output function, too, is usually not exact. Each measurement is faulty. The measurement errors will be called $w(t)$. Therefore the following system equations arise:
\[
\begin{align*}
x(t + 1) &= A(t)x(t) + G(t)u(t) + v(t) \\
y(t) &= c(t)x(t) + w(t)
\end{align*}
\]

The system error \( v(t) \) and the measurement error \( w(t) \) are not known. As far as systems are concerned which are interpreted with the help of the Kalman filter, these two errors are considered as Gaussian distributed random vectors (therefore the expression “stochastically disturbed systems”). Therefore the system can be calculated, if the corresponding expected values for \( v(t) \) and \( w(t) \) as well as the covariance matrices are known.

The estimation of the state of the system is carried out in the same way as in the Gaussian-Markov-estimation. However, the Kalman filter is a recursive algorithm which is based only on the current measurements \( y(t) \) and the latest state \( x(t) \). The latter implicitly also includes the knowledge about earlier measurements.

A suitable estimate value \( x(0) \), which is interpreted as the expected value of a random variable for \( x(0) \), must be indicated for the initial value \( x(0) \). This variable should have an expected error value of 0 and the covariance matrix \( P_0 \) which also has to be indicated. At a certain time \( t \) the expected values of both disturbances \( v(t) \) and \( w(t) \), should be 0 and their covariances should be \( Q(t) \) and \( R(t) \). \( x(t) \), \( v(t) \) and \( w(t) \) will usually be assumed to be not correlated (any kind of noise-process can be modelled - however the development of the necessary matrices by the user will be considerably more demanding). The following conditions must be met by the searched estimate values \( x^t \):

- The estimate values \( x^t \) are linearly dependent on the actual value \( x(t) \) and on the measurement sequence \( y(0), y(1), \ldots, y(t) \).
- \( x^t \) being hereby considered to meet its expectations, i.e. \( Ex^t \) = \( Ex(t) \).
- The grade criterion for \( x^t \) is the criterion of minimal variance, i.e. \( \text{variance of the estimationerror defined as } x(t) - x^t \) being as small as possible.

After the initialization
\[
\hat{x}(0) = x_0, \quad \hat{P}(0) = P_0
\]
at each point in time \( t \) the Kalman filter executes the following calculation steps:

\[
\begin{align*}
(K - III) & \quad K(t) = \frac{\hat{P}(t)C^t(t)}{C(t)\hat{P}(t)C^t(t)+R(t)} \\
(K - IV) & \quad x^t = \hat{x}(t) + K(t)(y(t) - C(t)\hat{x}(t)) \\
(K - V) & \quad \hat{P}(t) = \hat{P}(t) - K(t)C(t)\hat{P}(t) \\
(K - I) & \quad \hat{x}(t+1) = A(t)x^t + G(t)u(t) \\
(K - II) & \quad \hat{P}(t+1) = A(t)\hat{P}(t)A^t(t) + Q(t)
\end{align*}
\]

Hereby \( \hat{P}(t) \) is the covariance matrix of the estimation error, \( \hat{x}(t) \) is the extrapolation value respective the prediction value of the state, \( \hat{P}(t) \) are the covariances of the prediction error \( \hat{x} - x \), \( K \) is the amplifier matrix (the so called Kalman gain), and \( X^t \) is the transposed of a matrix \( X \).

Please note that the prediction of the future state is also possible with the equation \( (K-I) \). Sometimes this is very useful in image processing in order to determine “regions of interest” in the next image.

As mentioned above, it is much more demanding to model any kind of noise processes. If for example the system noise and the measurement noise are correlated with the corresponding covariance matrix \( L \), the equations for the Kalman gain and the error covariance matrix have to be modified:

\[
\begin{align*}
(K - III) & \quad K(t) = \frac{\hat{P}(t)C^t(t)+L(t)}{C(t)\hat{P}(t)+C(t)L(t)+C^t(t)\hat{P}(t)+L^t(t)} \\
(K - V) & \quad \hat{P}(t) = (\hat{P}(t) - K(t)C(t)\hat{P}(t))\hat{P}(t) - K(t)L(t)
\end{align*}
\]

This means that the user himself has to establish the linear system equations from \( (K-I) \) up to \( (K-V) \) with respect to the actual problem. The user must therefore develop a mathematical model upon which the solution to the problem can be based. Statistical characteristics describing the inaccuracies of the system as well as the measurement errors, which are to be expected, thereby have to be estimated if they cannot be calculated exactly. Therefore the following individual steps are necessary:

1. Developing a mathematical model
2. Selecting characteristic state variables
3. Establishing the equations describing the changes of these state variables and their linearization (matrices A and G)
4. Establishing the equations describing the dependency of the measurement values of the system on the state variables and their linearization (matrix C)
5. Developing or estimating of statistical dependencies between the system disturbances (matrix Q)
6. Developing or estimating of statistical dependencies between the measurement errors (matrix R)
7. Initialization of the initial state

As mentioned above, the initialization of the system (point 7) hereby necessitates to indicate an estimate \( x_0 \) of the state of the system at the time 0 and the corresponding covariance matrix \( P_0 \). If the exact initial state is not known, it is recommendable to set the components of the vector \( x_0 \) to the average values of the corresponding range, and to set high values for \( P_0 \) (about the size of the squares of the range). After a few iterations (when the number of the accumulated measurement values in total has exceeded the number of the system values), the values which have been determined in this way are also useable.

If on the other hand the initial state is known exactly, all entries for \( P_0 \) have to be set to 0, because \( P_0 \) describes the covariances of the error between the estimated value \( x_0 \) and the actual value \( x(0) \).

THE FILTER ROUTINE:

A Kalman filter is dependent on a range of data which can be organized in four groups:

- **Model parameter**: transition matrix \( A \), control matrix \( G \) including the parameter \( u \) and the measurement matrix \( C \)
- **Model stochastic**: system-error covariance matrix \( Q \), system-error - measurement-error covariance matrix \( L \), and measurement-error covariance matrix \( R \)
- **Measurement vector**: \( y \)
- **History of the system**: extrapolation vector \( \hat{x} \) and extrapolation-error covariance matrix \( \hat{P} \)

Thereby many systems can work without input “from outside”, i.e. without \( G \) and \( u \). Further, system errors and measurement errors are normally not correlated (\( L \) is dropped).

Actually the data necessary for the routine will be set by the following parameters:

- **Dimension**: This parameter includes the dimensions of the status vector, the measurement vector and the controller vector. **Dimension** thereby is a vector \([n,m,p]\), whereby ‘\( n \)’ indicates the number of the state variables, ‘\( m \)’ the number of the measurement values and ‘\( p \)’ the number of the controller members. For a system without determining control (i.e. without influence “from outside”) therefore \([n,m,0]\) has to be passed.
- **Model**: This parameter includes the lined up matrices (vectors) ‘\( A,C,Q,G,u \)’ and (if necessary) ‘\( L \)’ having been stored in row-major order. **Model** therefore is a vector of the length \( n \times n + n \times m + n \times p + p[+n \times m] \). The last summand is dropped, in case the system errors and measurement errors are not correlated, i.e. there is no value for ‘\( L \)’.
- **Measurement**: This parameter includes the matrix ‘\( R \)’ which has been stored in row-major order, and the measurement vector ‘\( y \)’ lined up. **Measurement** therefore is a vector of the dimension \( n \times m + m \).
- **PredictionIn / PredictionOut**: These two parameters include the matrix \( \hat{P} \) (the extrapolation-error covariance matrix) which has been stored in row-major order and the extrapolation vector \( \hat{x} \) lined up. This means, they are vectors of the length \( n \times n + n \). **PredictionIn** therefore is an input parameter, which must contain \( \hat{P}(t) \) and \( \hat{x}(t) \) at the current time \( t \). With **PredictionOut** the routine returns the corresponding predictions \( \hat{P}(t+1) \) and \( \hat{x}(t+1) \).
- **Estimate**: With this parameter the routine returns the matrix \( \hat{P} \) (the estimation-error covariance matrix) which has been stored in row-major order and the estimated state \( \hat{x} \) lined up. **Estimate** therefore is a vector of the length \( n \times n + n \).

Please note that the covariance matrices \((Q, R, \hat{P}, \hat{P})\) must of course be symmetric.
Parameters

- **Dimension** (input_control) .................................................. integer-array \(\sim integer\)
The dimensions of the state vector, the measurement and the controller vector.
  Default value: [3,1,0]
  Typical range of values: \(0 \leq \text{Dimension} \leq 30\)

- **Model** (input_control) .................................................. real-array \(\sim real\)
The lined up matrices \(A, C, Q\), possibly \(G\) and \(u\), and if necessary \(L\) which have been stored in row-major order.
  Default value: [1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
  Typical range of values: \(0.0 \leq \text{Model} \leq 10000.0\)

- **Measurement** (input_control) ............................................ real-array \(\sim real\)
The matrix \(R\) stored in row-major order and the measurement vector \(y\) lined up.
  Default value: [1.2,1.0]
  Typical range of values: \(0.0 \leq \text{Measurement} \leq 10000.0\)

- **PredictionIn** (input_control) .......................................... real-array \(\sim real\)
The matrix \(\hat{P}\) (the extrapolation-error covariances) stored in row-major order and the extrapolation vector \(\hat{x}\) lined up.
  Default value: [0.0,0.0,0.0,0.0,0.0,180.5,0.0,0.0,0.0,100.0,0.0,100.0,0.0]
  Typical range of values: \(0.0 \leq \text{PredictionIn} \leq 10000.0\)

- **PredictionOut** (output_control) ....................................... real-array \(\sim real\)
The matrix \(P^*\) (the extrapolation-error covariances) stored in row-major order and the extrapolation vector \(\hat{x}\) lined up.

- **Estimate** (output_control) ............................................ real-array \(\sim real\)
The matrix \(\tilde{P}\) (the estimation-error covariances) stored in row-major order and the estimated state \(\tilde{x}\) lined up.

Example

* Typical procedure:
  * To initialize the variables, which describe the model, e.g., with
    `read_kalman('kalman.init', Dim, Mod, Meas, Pred)`
  * Generation of the first measurements (typical of the first image of an
    * image series) with an appropriate problem-specific procedure (there is a
      * fictitious procedure `extract_features` in example):
    * `extract_features(Image1, Meas, Meas1)`
  * first Kalman-Filtering:
    `filter_kalman(Dim, Mod, Meas1, Pred1, Pred1, Est1)`
  * To use the estimate value (if need be the prediction too)
    * with a problem-specific procedure (here `use_est`):
      * `use_est(Est1)`
  * To get the next measurements (e.g. from the next image):
    * `extract_next_features(Image2, Meas1, Meas2)`
  * if need be Update of the model parameter (a constant model)
    * second Kalman-Filtering:
      `filter_kalman(Dim, Mod, Meas2, Pred1, Pred2, Est2)`
    * `use_est(Est2)`
    * `extract_next_features(Image3, Meas2, Meas3)`
    * etc.

Result

If the parameter values are correct, the operator `filter_kalman` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

intersection_ll ( : : RowA1, ColumnA1, RowA2, ColumnA2, RowB1, ColumnB1, RowB2, ColumnB2 : Row, Column, IsParallel )

Calculate the intersection point of two lines.

intersection_ll is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator intersection_lines of the chapter Tools / Geometry instead.

The operator intersection_ll calculates the intersection point of two lines. As input the two points on each line are expected (RowA1, ColumnA1, RowA2, ColumnA2) and (RowB1, ColumnB1, RowB2, ColumnB2). The parameters Row and Column return the result of the calculation. If the lines are parallel, the values of Row and Column are undefined and IsParallel is 1. Otherwise, IsParallel is 0.

Attention

If the lines are parallel the values of Row and Column are undefined.

Parameters

- RowA1 (input_control) ........................................ point.y(-array) ⇒ real / integer
  Row coordinate of the first point of the first line.
- ColumnA1 (input_control) ....................................... point.x(-array) ⇒ real / integer
  Column coordinate of the first point of the first line.
- RowA2 (input_control) ........................................ point.y(-array) ⇒ real / integer
  Row coordinate of the second point of the first line.
- ColumnA2 (input_control) ....................................... point.x(-array) ⇒ real / integer
  Column coordinate of the second point of the first line.
- RowB1 (input_control) ........................................ point.y(-array) ⇒ real / integer
  Row coordinate of the first point of the second line.
- ColumnB1 (input_control) ....................................... point.x(-array) ⇒ real / integer
  Column coordinate of the first point of the second line.
- RowB2 (input_control) ........................................ point.y(-array) ⇒ real / integer
  Row coordinate of the second point of the second line.
- ColumnB2 (input_control) ....................................... point.x(-array) ⇒ real / integer
  Column coordinate of the second point of the second line.
17.13. TOOLS

\[ \text{Row (output_control)} \] \text{point.y(-array)} \sim \text{real}
Row coordinate of the intersection point.

\[ \text{Column (output_control)} \] \text{point.x(-array)} \sim \text{real}
Column coordinate of the intersection point.

\[ \text{IsParallel (output_control)} \] \text{number(-array)} \sim \text{integer}
Are the two lines parallel?

--- Example ---

\[
\text{dev_set_color ('black')}
\text{RowLine1} := 350
\text{ColLine1} := 250
\text{RowLine2} := 300
\text{ColLine2} := 300
\text{Rows} := 300
\text{Columns} := 50
\text{disp_line (WindowHandle, RowLine1, ColLine1, RowLine2, ColLine2)}
\]
\[
n := 0
\text{for Rows} := 40 \text{ to } 200 \text{ by } 4
\text{dev_set_color ('red')}
\text{disp_line (WindowHandle, Rows, Columns, Rows+n, Columns+n)}
\text{intersection_ll (Rows, Columns, Rows+n, Columns+n, RowLine1, ColLine1, \}
\text{RowLine2, ColLine2, Row, Column, IsParallel)}
\text{dev_set_color ('blue')}
\text{disp_line (WindowHandle, Row, Column-2, Row, Column+2)}
\text{disp_line (WindowHandle, Row-2, Column, Row+2, Column)}
\]
\[
n := n+8
\text{endfor}
\]

--- Result ---
\text{intersection_ll returns 2 (H_MSG_TRUE).}

--- Parallelization ---

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

--- Module ---

\[
\text{partition_lines ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn,}
\text{Feature, Operation, Min, Max : RowBeginOut, ColBeginOut,}
\text{RowEndOut, ColEndOut, FailRowBOut, FailColBOut, FailRowEOut,}
\text{FailColEOut )}
\]

Partition lines according to various criteria.

\text{partition_lines} is obsolete and is only provided for reasons of backward compatibility.

The operator \text{partition_lines} divides lines into two sets according to various criteria. For each input line the indicated features (\text{Feature}) are calculated. If each (\text{Operation = 'and'}) or at least one (\text{Operation = 'or'}) of the calculated features is within the given limits (\text{Min,Max}) the line is transferred into the first set (parameters \text{RowBeginOut to ColEndOut}), otherwise into the second set (parameters \text{FailRowBOut to FailColEOut}). The default values 'min' and 'max' of the parameters \text{Min} and \text{Max} are used to leave bottom and top limit, respectively, open.

Condition: \[ Min_i \leq Feature_i(Line) \leq Max_i \]

Possible values for \text{Feature}: 

HALCON 20.05.0.0
‘length’ (Euclidean) length of the line
‘row’ Line index of the center
‘column’ Column index of the center
‘phi’ Orientation of the line ($-\frac{\pi}{2} < \varphi \leq \frac{\pi}{2}$)

Attention
If only one feature is used the value of Operation is meaningless. Several features are processed according to the sequence in which they are passed.

Parameters

▷ RowBeginIn (input_control) .................................. line.begin.y-array $\sim$ integer
   Row coordinates of the starting points of the input lines.
▷ ColBeginIn (input_control) .................................. line.begin.x-array $\sim$ integer
   Column coordinates of the starting points of the input lines.
▷ RowEndIn (input_control) .................................. line.end.y-array $\sim$ integer
   Row coordinates of the ending points of the input lines.
▷ ColEndIn (input_control) .................................. line.end.x-array $\sim$ integer
   Column coordinates of the ending points of the input lines.
▷ Feature (input_control) .................................. string(-array) $\sim$ string
   Features to be used for selection.
   List of values: Feature $\in \{ \text{length}, \text{row}, \text{column}, \text{phi} \}$
▷ Operation (input_control) .................................. string $\sim$ string
   Desired combination of the features.
   List of values: Operation $\in \{ \text{and}, \text{or} \}$
▷ Min (input_control) .................................. string(-array) $\sim$ string / integer / real
   Lower limits of the features or ‘min’.
   Default value: ‘min’
▷ Max (input_control) .................................. string(-array) $\sim$ string / integer / real
   Upper limits of the features or ‘max’.
   Default value: ‘max’
▷ RowBeginOut (output_control) ............................... line.begin.y-array $\sim$ integer
   Row coordinates of the starting points of the lines fulfilling the conditions.
▷ ColBeginOut (output_control) ............................... line.begin.x-array $\sim$ integer
   Column coordinates of the starting points of the lines fulfilling the conditions.
▷ RowEndOut (output_control) ............................... line.end.y-array $\sim$ integer
   Row coordinates of the ending points of the lines fulfilling the conditions.
▷ ColEndOut (output_control) ............................... line.end.x-array $\sim$ integer
   Column coordinates of the ending points of the lines fulfilling the conditions.
▷ FailRowBOut (output_control) ............................. line.begin.y-array $\sim$ integer
   Row coordinates of the starting points of the lines not fulfilling the conditions.
▷ FailColBOut (output_control) ............................. line.begin.x-array $\sim$ integer
   Column coordinates of the starting points of the lines not fulfilling the conditions.
▷ FailRowEOut (output_control) ............................. line.end.y-array $\sim$ integer
   Row coordinates of the ending points of the lines not fulfilling the conditions.
▷ FailColEOut (output_control) ............................. line.end.x-array $\sim$ integer
   Column coordinates of the ending points of the lines not fulfilling the conditions.

Result
The operator partition_lines returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

```plaintext
read_kalman ( : : FileName : Dimension, Model, Measurement, Prediction )
```

Read the description file of a Kalman filter.

**read_kalman is obsolete and is only provided for reasons of backward compatibility.**

The operator `read_kalman` reads the description file `FileName` of a Kalman filter. Kalman filters return an estimate of the current state (or even the prediction of a future state) of a discrete, stochastically disturbed, linear system. They are successfully used in image processing, especially in the analysis of image sequences. A Kalman filtering is based on a mathematical model of the system to be examined which at any point in time has the following characteristics:

**Model parameter:** transition matrix $A$, control matrix $G$ including the controller output $u$ and the measurement matrix $C$

**Model stochastic:** system-error covariance matrix $Q$, system-error - measurement-error covariance matrix $L$ and measurement-error covariance matrix $R$

**Estimate of the initial state of the system:** state $x_0$ and corresponding covariance matrix $P_0$

Many systems do not need entries “from outside”, and therefore $G$ and $u$ can be dropped. Further, system errors and measurement errors are normally not correlated ($L$ is dropped). The characteristics mentioned above can be stored in an ASCII-file and then can be read with the help of the operator `read_kalman`. This ASCII-file must have the following structure:

**Dimension row**

+ content row
+ matrix $A$
+ matrix $C$
+ matrix $Q$
[+ matrix $G$ + vector $u$ ]
[+ matrix $L$ ]
+ matrix $R$
[+ matrix $P_0$ ]
[+ vector $x_0$ ]

The dimension row thereby is always of the following form:

$$n = <\text{integer}> \quad m = <\text{integer}> \quad p = <\text{integer}>$$

whereby $n$ indicates the number of the state variables, $m$ the number of the measurement values and $p$ the number of the controller members (see also `Dimension`). The maximal dimension will hereby be limited by a system constant ($= 30$ for the time being).

The content row has the following form:

$$A * C * Q * G * u * L * R * P * x *$$

and describes the following content of the file. Instead of ’*’, ’+’ (= parameter is available) respectively ’-’ (= parameter is missing) have to be set. Please note that only the parameters marked by [...] in the above list may be...
left out in the description file. If the initial state estimate $a_0$ is missing (i.e. 'x-'), the components of the vector will supposed to be 0.0. If the covariance matrix $P_0$ of the initial state estimate is missing (i.e. 'P-'), the error will be supposed to be tremendous. In this case the matrix elements will be set to 10000.0. This value seems to be very high, however, it is only sufficient if the range of components of the state vector $x$ is smaller to the tenth power. 

$(r \times s)$ matrices will be stored per row in the following form:

\[
< \text{comment, i.e. string} > \\
< a_{11} > < a_{12} > \cdots < a_{1s} > \\
\vdots \quad \ddots \quad \vdots \\
< a_{r1} > < a_{r2} > \cdots < a_{rs} >
\]

(the spaces and line feed characters can be chosen at will),

vectors will be stored correspondingly in the following form:

\[
< \text{comment, i.e. string} > \\
< a_1 > \cdots < a_k >
\]

The following parameter values are returned by the operator read_kalman:

**Dimension**: This parameter includes the dimensions of the status vector, the measurement vector and the controller vector. **Dimension** thereby is a vector $[n,m,p]$, whereby 'n' indicates the number of the state variables, 'm' the number of the measurement values and 'p' the number of the controller members. For a system without determining control (i.e. without influence “from outside”) therefore **Dimension** = $[n,m,0]$.

**Model**: This parameter includes the lined up matrices (vectors) $A, C, Q, G, u$ and (if necessary) 'L' having been stored in row-major order. **Model** therefore is a vector of the length $n \times n + n \times m + n \times n + n \times p + p \times m$. The last summand is dropped, in case the system errors and measurement errors are not correlated, i.e. there is no value for 'L'.

**Measurement**: This parameter includes the matrix 'R' which has been stored in row-major order. **Measurement** therefore is vector of the dimension $m \times m$.

**Prediction**: This parameter includes the matrix $P_0$ (the error covariance matrix of the initial state estimate) and the initial state estimate $x_0$ lined up. This means, it is a vector of the length $n \times n + n$.

### Parameters

- **FileName** (input_control) ................................................. filename.read $\sim$ string
  - Description file for a Kalman filter.
  - **Default value**: 'kalman.init'
- **Dimension** (output_control) ....................................... integer-array $\sim$ integer
  - The dimensions of the state vector, the measurement vector and the controller vector.
- **Model** (output_control) .............................................. real-array $\sim$ real
  - The lined up matrices $A, C, Q$, possibly $G$ and $u$, and if necessary $L$ stored in row-major order.
- **Measurement** (output_control) .................................... real-array $\sim$ real
  - The matrix $R$ stored in row-major order.
- **Prediction** (output_control) ........................................ real-array $\sim$ real
  - The matrix $P_0$ (error covariance matrix of the initial state estimate) stored in row-major order and the initial state estimate $x_0$ lined up.

### Example

* An example of the description-file:
*  
  * n=3 m=1 p=0
  * A+C+Q+G-u-L-R+F+x+
  * transition matrix A:
  * 1 1 0.5
  * 0 1 1
  * 0 0 1

* measurement matrix C:
  * 1 0 0
* system-error covariance matrix Q:
  * 54.3 37.9 48.0
  * 37.9 34.3 42.5
  * 48.0 42.5 43.7
* measurement-error covariance matrix R:
  * 1 2
* estimation-error covariance matrix (for the initial estimate) P0:
  * 0 0 0
  * 0 180.5 0
  * 0 0 100
* initial estimate x0:
  * 0 100 0
* the result of read_kalman with the upper description file
  * as input parameter:
  *
  * Dimension = [3, 1, 0]
  * Model = [1.0, 1.0, 0.5, 0.0, 1.0, 1.0, 0.0, 0.0, 1.0, 0.0, 0.0, 0.0, 54.3, 37.9, 48.0, 37.9, 34.3, 42.5, 48.0, 42.5, 43.7]
  * Measurement = [1.2]
  * Prediction = [0.0, 0.0, 0.0, 0.0, 180.5, 0.0, 0.0, 0.0, 100.0, 0.0, 100.0, 0.0, 0.0, 0.0, 0.0].

Result

If the description file is readable and correct, the operator read_kalman returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

select_lines ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn,
  Feature, Operation, Min, Max : RowBeginOut, ColBeginOut,
  RowEndOut, ColEndOut )

Select lines according to various criteria.

select_lines is obsolete and is only provided for reasons of backward compatibility.

The operator select_lines chooses lines according to various criteria. For every input line the indicated features (Feature) are calculated. If each (Operation = 'and') or at least one (Operation = 'or') of the calculated features is within the given limits (Min, Max) the line is transferred into the output. The default values 'min' and 'max' of the parameters Min and Max are used to leave bottom and top limits, respectively, open.

Condition: \( Min_i \leq Feature_i(Line) \leq Max_i \)

Possible values for Feature:
'length' (Euclidean) length of the line
'row' Line index of the center
'column' Column index of the center
'phi' Orientation of the line ($\frac{\pi}{2} < \varphi \leq \frac{\pi}{2}$)

Attention
If only one feature is used the value of Operation is meaningless. Several features are processed according to
the sequence in which they are passed.

Parameters

- **RowBeginIn** (input_control) ........................................ line.begin.y-array $\sim$ integer
  Row coordinates of the starting points of the input lines.
- **ColBeginIn** (input_control) ........................................ line.begin.x-array $\sim$ integer
  Column coordinates of the starting points of the input lines.
- **RowEndIn** (input_control) ........................................ line.end.y-array $\sim$ integer
  Row coordinates of the ending points of the input lines.
- **ColEndIn** (input_control) ........................................ line.end.x-array $\sim$ integer
  Column coordinates of the ending points of the input lines.
- **Feature** (input_control) ........................................ string(-array) $\sim$ string
  Features to be used for selection.
  Default value: 'length'
  List of values: Feature $\in$ {'length', 'row', 'column', 'phi'}
- **Operation** (input_control) ........................................ string $\sim$ string
  Desired combination of the features.
  Default value: 'and'
  List of values: Operation $\in$ {'and', 'or'}
- **Min** (input_control) ........................................ string(-array) $\sim$ string / integer / real
  Lower limits of the features or 'min'.
  Default value: 'min'
- **Max** (input_control) ........................................ string(-array) $\sim$ string / integer / real
  Upper limits of the features or 'max'.
  Default value: 'max'
- **RowBeginOut** (output_control) ................................. line.begin.y-array $\sim$ integer
  Row coordinates of the starting points of the output lines.
- **ColBeginOut** (output_control) ................................. line.begin.x-array $\sim$ integer
  Column coordinates of the starting points of the output lines.
- **RowEndOut** (output_control) ................................. line.end.y-array $\sim$ integer
  Row coordinates of the ending points of the output lines.
- **ColEndOut** (output_control) ................................. line.end.x-array $\sim$ integer
  Column coordinates of the ending points of the output lines.

Result
The operator select_lines returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise
an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
sobel_amp, edges_image, threshold, hysteresis_threshold, split_skeleton_region, split_skeleton_lines

Possible Successors

**select_lines_longest** { : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn, Num : RowBeginOut, ColBeginOut, RowEndOut, ColEndOut }

Select the longest input lines.

**select_lines_longest** is obsolete and is only provided for reasons of backward compatibility.

The operator **select_lines_longest** selects the **Num** longest input lines from the input lines described by the tuples **RowBeginIn**, **ColBeginIn**, **RowEndIn** and **ColEndIn**.

**Parameters**

- **RowBeginIn** (input_control) .............................................. line.begin.y-array ~ integer
  Row coordinates of the starting points of the input lines.
- **ColBeginIn** (input_control) .............................................. line.begin.x-array ~ integer
  Column coordinates of the starting points of the input lines.
- **RowEndIn** (input_control) .............................................. line.end.y-array ~ integer
  Row coordinates of the ending points of the input lines.
- **ColEndIn** (input_control) .............................................. line.end.x-array ~ integer
  Column coordinates of the ending points of the input lines.
- **Num** (input_control) ...................................................... integer ~ integer
  (Maximum) desired number of output lines.
  Default value: 10

- **RowBeginOut** (output_control) ......................................... line.begin.y-array ~ integer
  Row coordinates of the starting points of the output lines.
- **ColBeginOut** (output_control) ......................................... line.begin.x-array ~ integer
  Column coordinates of the starting points of the output lines.
- **RowEndOut** (output_control) ............................................ line.end.y-array ~ integer
  Row coordinates of the ending points of the output lines.
- **ColEndOut** (output_control) ............................................ line.end.x-array ~ integer
  Column coordinates of the ending points of the output lines.

**Result**

The operator **select_lines_longest** returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**update_kalman** ( : : FileName, DimensionIn, ModelIn, MeasurementIn : DimensionOut, ModelOut, MeasurementOut )

*Read an update file of a Kalman filter.*

*update_kalman* is obsolete and is only provided for reasons of backward compatibility.

The operator *update_kalman* reads the update file *FileName* of a Kalman filter. Kalman filters return an estimate of the current state (or even the prediction of a future state) of a discrete, stochastically disturbed, linear system.

A Kalman filtering is based on a mathematical model of the system to be examined which at any point in time has the following characteristics:

**Model parameter:** transition matrix $A$, control matrix $G$ including the controller output $u$ and the measurement matrix $C$

**Model stochastic:** system-error covariance matrix $Q$, system-error - measurement-error covariance matrix $L$ and measurement-error covariance matrix $R$

**Measurement vector:** $y$

**History of the system:** extrapolation vector $\hat{x}$ and extrapolation-error covariance matrix $\hat{P}$

Many systems do not need entries “from outside” and therefore $G$ and $u$ can be dropped. Further, system errors and measurement errors are normally not correlated ($L$ is dropped). Some of the characteristics mentioned above may change dynamically (from one iteration to the next). The operator *update_kalman* serves to modify parts of the system according to an update file (ASCII) with the following structure (see also *read_kalman*):

- **Dimension row**
  - + content row
  - + matrix $A$
  - + matrix $C$
  - + matrix $Q$
  - + matrix $G$ + vector $u$
  - + matrix $L$
  - + matrix $R$

The dimension row thereby has the following form:

$$n = \langle \text{integer} \rangle \quad m = \langle \text{integer} \rangle \quad p = \langle \text{integer} \rangle$$

whereby $n$ indicates the number of the state variables, $m$ the number of the measurement values and $p$ the number of the controller members (see also *DimensionIn*/*DimensionOut*). The maximal dimension will hereby be limited by a system constant (= 30 for the time being). As in this case changes should take effect at a valid model, the dimensions $n$ and $m$ are invariant (and will only be indicated for purposes of control).

The content row has the following form:

$$A \times C \times Q \times G \times u \times L \times R$$

and describes the further content of the file. Instead of ‘*’, ‘+’ (= parameter is available) respectively ‘-’ (= parameter is missing) has to be set. In contrast to description files for *read_kalman*, the system description needs not be complete in this case. Only those parts of the system which are changed must be indicated. The indication of estimated values is unnecessary, as these values must stem from the latest filtering according to the structure of the filter.

$(r \times s)$ matrices will be stored in row-major order in the following form:

```
< comment, i.e. string >
< a_{11} > < a_{12} > \cdots < a_{1s} >
\vdots \quad \ddots \quad \vdots
< a_{r1} > < a_{r2} > \cdots < a_{rs} >
```
(the spaces/line feed characters can be chosen at will), vectors will be stored correspondingly in the following form:

\[
< \text{comment, i.e. string} > \\
< a_1 > \cdots < a_k >
\]

The following parameter values of the operator `read_kalman` will be changed:

**DimensionIn / DimensionOut**: These parameters include the dimensions of the state vector, measurement vector and controller vector and therefore are vectors \([n,m,p]\), whereby 'n' indicates the number of the state variables, 'm' the number of the measurement values and 'p' the number of the controller members. 'n' and 'm' are invariant for a given system, i.e. they must not differ from corresponding input values of the update file. For a system without without influence “from outside” \(p = 0\).

**ModelIn / ModelOut**: These parameters include the lined up matrices (vectors) 'A, C, Q, G, u' and if necessary 'L' which have been stored in row-major order. **ModelIn / ModelOut** therefore are vectors of the length \(n \times n + m \times n + n \times n + p + p + n \times m\). The last summand is dropped if system errors and measurement errors are not correlated, i.e. no value has been set for 'L'.

**MeasurementIn / MeasurementOut**: These parameters include the matrix 'R' stored in row-major order, and therefore are vectors of the dimension \(m \times m\).

---

**Parameters**

- **FileName (input_control)**: Update file for a Kalman filter.  
  Default value: 'kalman.updt'

- **DimensionIn (input_control)**: The dimensions of the state vector, measurement vector and controller vector.  
  Default value: \([3,1,0]\)  
  Typical range of values: \(0 \leq \text{DimensionIn} \leq 30\)

- **ModelIn (input_control)**: The lined up matrices A,C,Q, possibly G and u, and if necessary L which all have been stored in row-major order.  
  Default value: \([1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,0.0,1.0,1.0,0.0,0.0,54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]\)  
  Typical range of values: \(0.0 \leq \text{ModelIn} \leq 10000.0\)

- **MeasurementIn (input_control)**: The matrix R stored in row-major order.  
  Default value: \([1,2]\)  
  Typical range of values: \(0.0 \leq \text{MeasurementIn} \leq 10000.0\)

- **DimensionOut (output_control)**: The dimensions of the state vector, measurement vector and controller vector.

- **ModelOut (output_control)**: The lined up matrices A,C,Q, possibly G and u, and if necessary L which all have been stored in row-major order.

- **MeasurementOut (output_control)**: The matrix R stored in row-major order.

---

**Example**

* The following values are describing the system  

* DimensionIn = \([3,1,0]\)  
  * ModelIn = \([1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]\)  
  * MeasurementIn = \([1,2]\)  

* An example of the Updatefile:

* n=3 m=1 p=0
*A+C-Q-G-u-L-R-*
* transitions at time t=15:
*  2 1 1
*  0 2 2
*  0 0 2
*
* the results of update_kalman:
*
* DimensionOut = [3,1,0]
* ModelOut  = [2.0,1.0,0.0,0.0,2.0,2.0,0.0,0.0,2.0,1.0,0.0,0.0,
*                54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
* MeasurementOut = [1.2]

Result
If the update file is readable and correct, the operator update_kalman returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

17.14 XLD

union_straight_contours_histo_xld ( Contours : UnionContours,
    SelectedContours : RefLineStartRow, RefLineStartColumn,
    RefLineEndRow, RefLineEndColumn, Width, MaxWidth,
    FilterSize : HistoValues )

Compute the union of neighboring straight contours that have a similar distance from a given line.

union_straight_contours_histo_xld is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators of the chapter 1D Measuring instead.

union_straight_contours_histo_xld merges neighboring XLD contours Contours if certain criteria are fulfilled.

The maximum and minimum distances of the contours to a given reference line are calculated. From this distances a histogram is created. If the histogram should be smoothed, FilterSize must be greater than one. Afterwards, the resulting histogram is divided into ranges (from minima to minima). Contours which lie in the same range are concatenated to a new contour. If the width of the range is greater than MaxWidth, all contours in this range are ignored (removed). If a contour lies in two ranges or more it is ignored, too. If there are parallel contours, there is a risk of merging neighboring contours.

The parameters of the regression lines are calculated newly for merged contours.

The resulting contours cannot be displayed.

Attention
Before the contour parameters can be returned by union_straight_contours_histo_xld, the parameters of the regression line to the contour must be calculated by calling regress_contours_xld. Note further that already closed contours are not considered for a union anymore.
Parameters

- **Contours** (input_object) - Input XLD contours.
- **UnionContours** (output_object) - Output XLD contours.
- **SelectedContours** (output_object) - Output XLD contours.
- **RefLineStartRow** (input_control) - y coordinate of the starting point of the reference line.
  Default value: 0
- **RefLineStartColumn** (input_control) - x coordinate of the starting point of the reference line.
  Default value: 0
- **RefLineEndRow** (input_control) - y coordinate of the endpoint of the reference line.
  Default value: 0
- **RefLineEndColumn** (input_control) - x coordinate of the endpoint of the reference line.
  Default value: 0
- **Width** (input_control) - Maximum distance.
  Default value: 1
- **MaxWidth** (input_control) - Maximum Width between two minimas.
  Default value: 1
- **FilterSize** (input_control) - Size of Smoothfilter
  Default value: 1
  Typical range of values: $1 \leq \text{FilterSize} \leq 63$
- **HistoValues** (output_control) - Output Values of Histogram.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

18.1 Component-Based

clear_component_model ( : : ComponentModelID : )

Free the memory of a component model.

The operator clear_component_model frees the memory of a component model that was created by create_component_model or create_trained_component_model. After calling clear_component_model, the model can no longer be used. The handle ComponentModelID becomes invalid.

Parameters

ComponentModelID (input_control) component_model ~ handle

Handle of the component model.

Result

If the handle of the model is valid, the operator clear_component_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ComponentModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_component_model, create_trained_component_model, read_component_model, write_component_model

Module

clear_training_components ( : : ComponentTrainingID : )

Free the memory of a component training result.
The operator \texttt{clear\_training\_components} frees the memory of a training result that was created by \texttt{train\_model\_components}. After calling \texttt{clear\_training\_components}, the training result can no longer be used. The handle \texttt{ComponentTrainingID} becomes invalid.

\end{itemize}

\texttt{cluster\_model\_components}

\begin{verbatim}
( TrainingImages : ModelComponents : ComponentTrainingID, 
  AmbiguityCriterion, MaxContourOverlap, ClusterThreshold : )
\end{verbatim}

Adopt new parameters that are used to create the model components into the training result.

With \texttt{cluster\_model\_components} you can modify parameters \textit{after} a first training has been performed using \texttt{train\_model\_components}. \texttt{cluster\_model\_components} sets the criterion \texttt{AmbiguityCriterion} that is used to solve the ambiguities, the maximum contour overlap \texttt{MaxContourOverlap}, and the cluster threshold of the training result \texttt{ComponentTrainingID} to the specified values. A detailed description of these parameters can be found in the documentation of \texttt{train\_model\_components}. By modifying these parameters, the way in which the initial components are merged into rigid model components changes. For example, the greater the cluster threshold is chosen, the fewer initial components are merged. You can select suitable parameter values interactively by repeatedly calling \texttt{inspect\_clustered\_components} with different parameter values and then setting the chosen values by using \texttt{get\_training\_components}.

The rigid model components are returned in \texttt{ModelComponents}. In order to receive reasonable results, it is essential that the same training images that were used to perform the training with \texttt{train\_model\_components} are passed in \texttt{TrainingImages}. The pose of the newly clustered components within the training images is determined using the shape-based matching. As in \texttt{train\_model\_components}, one can decide whether the shape models should be pregenerated by using \texttt{set\_system}('pregenerate\_shape\_models',\ldots). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. \texttt{set\_system}('border\_shape\_models',\ldots) can be used to determine whether the models must lie completely within the training images or whether they can extend partially beyond the image border.
**18.1. COMPONENT-BASED**

### Parameters

- **TrainingImages** (input_object) ........................................ object: byte / uint2
  Training images that were used for training the model components.

- **ModelComponents** (output_object) ........................................ region(-array) ⇒ object
  Contour regions of rigid model components.

- **ComponentTrainingID** (input_control) .............................. component_training ⇒ handle
  Handle of the training result.

- **AmbiguityCriterion** (input_control) ................................. string ⇒ string
  Criterion for solving the ambiguities.
  Default value: 'rigidity'
  List of values: AmbiguityCriterion ∈ {'distance', 'orientation', 'distance_orientation', 'rigidity'}

- **MaxContourOverlap** (input_control) ................................. real ⇒ real
  Maximum contour overlap of the found initial components.
  Default value: 0.2
  Suggested values: MaxContourOverlap ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: 0 <= MaxContourOverlap && MaxContourOverlap <= 1

- **ClusterThreshold** (input_control) ..................................... real ⇒ real
  Threshold for clustering the initial components.
  Default value: 0.5
  Suggested values: ClusterThreshold ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: 0 <= ClusterThreshold && ClusterThreshold <= 1

### Example

* Get the model image.
  read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
  gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
  gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
  gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
  concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images
  gen_empty_obj (TrainingImages)
  for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i$'02'+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
  endfor
* Extract the model components and train the relations.
  train_model_components (ModelImage, InitialComponentRegions, \ TrainingImages, ModelComponents, 22, 60, 30, 0.65, \ 0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.5, \ ComponentTrainingID)
* Find the best value for the parameter ClusterThreshold.
  inspect_clustered_components (ModelComponents, ComponentTrainingID, \ 'rigidity', 0.2, 0.4)
* Adopt the ClusterThreshold into the training result.
  cluster_model_components (ModelComponents, \ ComponentTrainingID, 'rigidity', 0.2, 0.4)
* Create the component model based on the training result.
  create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, \ 0.5, 'auto', 'auto', 'none', \ 'use_polarity', 'false', ComponentModelID, \ RootRanking)
If the parameter values are correct, the operator `cluster_model_components` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system` (`'no_object_result',<Result>`). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `train_model_components`
- `inspect_clustered_components`

**Possible Successors**

- `get_training_components`
- `create_trained_component_model`
- `modify_component_relations`
- `write_training_components`
- `get_component_relations`
- `clear_training_components`

**Module**

```
create_component_model { ModelImage,  
  ComponentRegions : : VariationRow, VariationColumn,  
  VariationAngle, AngleStart, AngleExtent, ContrastLowComp,  
  ContrastHighComp, MinSizeComp, MinContrastComp, MinScoreComp,  
  NumLevelsComp, AngleStepComp, OptimizationComp, MetricComp,  
  PregenerationComp : ComponentModelID, RootRanking }
```

Prepare a component model for matching based on explicitly specified components and relations.

`create_component_model` prepares patterns, which are passed in the form of a model image `ModelImage` and several regions `ComponentRegions`, as a component model for matching. The output parameter `ComponentModelID` is a handle for this model, which is used in subsequent calls to `find_component_model`. In contrast to `create_trained_component_model`, no preceding training with `train_model_components` needs to be performed before calling `create_component_model`.

Each of the regions passed in `ComponentRegions` describes a separate model component. Later, the index of a component region in `ComponentRegions` is used to denote the model component. The reference point of a component is the center of gravity of its associated region, which is passed in `ComponentRegions`. It can be calculated by calling `area_center`.

The relative movements (relations) of the model components can be set by passing `VariationRow`, `VariationColumn`, and `VariationAngle`. Because directly passing the relations is complicated, instead of the relations the variations of the model components are passed. The variations describe the movements of the components independently from each other relative to their poses in the model image `ModelImage`. The parameters `VariationRow` and `VariationColumn` describe the movement of the components in row and column direction by $\pm \frac{1}{2}$ `VariationRow` and $\pm \frac{1}{2}$ `VariationColumn`, respectively. The parameter `VariationAngle` describes the angle variation of the component by $\pm \frac{1}{2}$ `VariationAngle`. Based on these values, the relations are automatically computed. The three parameters must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as `ComponentRegions`, in which case each parameter element refers to the corresponding model component in `ComponentRegions`.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations of the component model in an image.

Internally, a separate shape model is built for each model component (see `create_shape_model`). Therefore, the parameters `ContrastLowComp`, `ContrastHighComp`, `MinSizeComp`, `MinContrastComp`, `MinScoreComp`, `NumLevelsComp`, `AngleStepComp`, `OptimizationComp`, `MetricComp`, and `PregenerationComp` correspond to the parameters of `create_shape_model`, with the following differences: First, in the parameter `Contrast` of `create_shape_model` the upper as well as the lower threshold for the hysteresis threshold method can be passed. Additionally, a third value, which suppresses small connected
18.1. COMPONENT-BASED

Optimization

the parameter 'auto' set to MinScoreComp analysis only leads to meaningful results if the value for tational symmetries of the model components and similarities between the model components. However, this create_shape_model be passed when preparing the shape model using MinContrastComp ing parameter MinScoreComp cide whether the shape models should be completely pregenerated or not. A third difference concerning the create_trained_component_model uses a separate parameter PregenerationComp in order to de- cide whether the shape models should be completely pregenerated or not. A third difference concerning the parameter MinScoreComp should be noted. When using the shape-based matching, this parameter needs not be passed when preparing the shape model using create_shape_model, but only during the search using find_shape_model. In contrast, when preparing the component model it is favorable to analyze rotational symmetries of the model components and similarities between the model components. However, this analysis only leads to meaningful results if the value for MinScoreComp that is used during the search (see find_component_model) is already approximately known.

In addition to the parameters ContrastLowComp, ContrastHighComp, and MinSizeComp also the pa- rameters MinContrastComp, NumLevelsComp, AngleStepComp, and OptimizationComp can be au- tomatically determined by passing 'auto' for the respective parameters.

All component-specific input parameters (parameter names terminate with the suffix Comp) must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as the number of regions in ComponentRegions, in which case each parameter element refers to the corresponding element in ComponentRegions.

In addition to the individual shape models, the component model also contains information about the way the single model components must be searched relative to each other using find_component_model in order to minimize the computation time of the search. For this, the components are represented in a tree structure. First, the component that stands at the root of this search tree (root component) is searched. Then, the remaining components are searched relative to the pose of their predecessor in the search tree.

The root component can be passed as an input parameter of find_component_model during the search. To what extent a model component is suited to act as the root component depends on several factors. In principle, a model component that can be found in the image with a high probability should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as the root component. Additionally, the computation time that is associated with the root component during the search can serve as a criterion. A ranking of the model components that is based on the latter criterion is returned in RootRanking. In this parameter the indices of the model components are sorted in descending order according to their associated search time, i.e., RootRanking[0] contains the index of the model component that, chosen as root component, allows the fastest search. Note that the ranking returned in RootRanking represents only a coarse estimation. Furthermore, the calculation of the root ranking assumes that the image size as well as the value of the system parameter 'border_shape_models' are identical when calling create_component_model and find_component_model.

Parameters

- **ModelImage** (input_object) ...........................................(multichannel-)image  ~ object : byte / uint2
  Input image from which the shape models of the model components should be created.

- **ComponentRegions** (input_object) .................................region-array  ~ object
  Input regions from which the shape models of the model components should be created.

- **VariationRow** (input_control) ....................................integer(-array)  ~ integer
  Variation of the model components in row direction.
  Suggested values: VariationRow ∈ {0, 1, 2, 3, 4, 5, 10, 20, 30, 40, 50, 100, 150}
  Restriction: VariationRow >= 0

- **VariationColumn** (input_control) .................................integer(-array)  ~ integer
  Variation of the model components in column direction.
  Suggested values: VariationColumn ∈ {0, 1, 2, 3, 4, 5, 10, 20, 30, 40, 50, 100, 150}
  Restriction: VariationColumn >= 0

- **VariationAngle** (input_control) .................................angle.rad(-array)  ~ real
  Angle variation of the model components.
  Suggested values: VariationAngle ∈ {0.0, 0.017, 0.035, 0.05, 0.07, 0.09, 0.17, 0.35, 0.52, 0.67, 0.87}
  Restriction: VariationAngle >= 0

HALCON 20.05.0.0
AngleStart (input_control) \( \ldots \) \( \text{angle.rad} \sim \text{real} \)
Smallest rotation of the component model.
Default value: -0.39
Suggested values: \( \text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\} \)

AngleExtent (input_control) \( \ldots \) \( \text{angle.rad} \sim \text{real} \)
Extent of the rotation of the component model.
Default value: 0.79
Suggested values: \( \text{AngleExtent} \in \{6.28, 3.14, 1.57, 0.79, 0.39\} \)
Restriction: \( \text{AngleExtent} \geq 0 \)

ContrastLowComp (input_control) \( \ldots \) \( \text{integer(-array)} \sim \text{integer / string} \)
Lower hysteresis threshold for the contrast of the components in the model image.
Default value: 'auto'
Suggested values: \( \text{ContrastLowComp} \in \{'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\} \)
Restriction: \( \text{ContrastLowComp} \geq 0 \)

ContrastHighComp (input_control) \( \ldots \) \( \text{integer(-array)} \sim \text{integer / string} \)
Upper hysteresis threshold for the contrast of the components in the model image.
Default value: 'auto'
Suggested values: \( \text{ContrastHighComp} \in \{'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\} \)
Restriction: \( \text{ContrastHighComp} \geq \text{ContrastLowComp} \)

MinSizeComp (input_control) \( \ldots \) \( \text{integer(-array)} \sim \text{integer / string} \)
Minimum size of the contour regions in the model.
Default value: 'auto'
Suggested values: \( \text{MinSizeComp} \in \{'auto', 0, 5, 10, 20, 30, 40\} \)
Restriction: \( \text{MinSizeComp} \geq 0 \)

MinContrastComp (input_control) \( \ldots \) \( \text{integer(-array)} \sim \text{integer / string} \)
Minimum contrast of the components in the search images.
Default value: 'auto'
Suggested values: \( \text{MinContrastComp} \in \{'auto', 10, 20, 30, 40\} \)
Restriction: \( \text{MinContrastComp} \leq \text{ContrastLowComp} \)

MinScoreComp (input_control) \( \ldots \) \( \text{real(-array)} \sim \text{real} \)
Minimum score of the instances of the components to be found.
Default value: 0.5
Suggested values: \( \text{MinScoreComp} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: \( 0 \leq \text{MinScoreComp} \leq 1 \)

NumLevelsComp (input_control) \( \ldots \) \( \text{integer(-array)} \sim \text{integer / string} \)
Maximum number of pyramid levels for the components.
Default value: 'auto'
List of values: \( \text{NumLevelsComp} \in \{'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\} \)

AngleStepComp (input_control) \( \ldots \) \( \text{angle.rad(-array)} \sim \text{angle.rad / string} \)
Step length of the angles (resolution) for the components.
Default value: 'auto'
Suggested values: \( \text{AngleStepComp} \in \{'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\} \)
Restriction: \( \text{AngleStepComp} \geq 0 \)

OptimizationComp (input_control) \( \ldots \) \( \text{string} \sim \text{string} \)
Kind of optimization for the components.
Default value: 'auto'
List of values: \( \text{OptimizationComp} \in \{'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'\} \)

MetricComp (input_control) \( \ldots \) \( \text{string(-array)} \sim \text{string} \)
Match metric used for the components.
Default value: 'use_polarity'
List of values: \( \text{MetricComp} \in \{'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'\} \)
18.1. COMPONENT-BASED

- **PregenerationComp** (input_control) ... string(-array) \(\sim string\)
  Complete pregeneration of the shape models for the components if equal to ‘true’.
  **Default value:** ‘false’
  **List of values:** PregenerationComp \(\in\) {'true', 'false'}

- **ComponentModelID** (output_control) ... component_model \(\sim handle\)
  Handle of the component model.

- **RootRanking** (output_control) ... integer(-array) \(\sim integer\)
  Ranking of the model components expressing the suitability to act as the root component.

---

**Example**

* Read the model image.
  `read_image (ModelImage, 'model_image.tif')`
* Describe the model components.
  `gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)`
  `gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)`
  `gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)`
  `concat_obj (ComponentRegions, Rectangle2, ComponentRegions)`
  `concat_obj (ComponentRegions, Rectangle3, ComponentRegions)`
* Create the component model by explicitly specifying the relations.
  `create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \`
  rad(360), 15, 40, 15, 10, 0.8, 'auto', 'auto', \`
  'none', 'use_polarity', 'false', ComponentModelID, \`
  RootRanking)`
* Find the component model in a run-time image.
  `read_image (SearchImage, 'search_image.tif')`
  `find_component_model (SearchImage, ComponentModelID, RootRanking, 0, \`
  rad(360), 0.5, 0, 0.5, 'stop_search', \`
  'search_from_best', 'none', 0.8, 'least_squares', 0, \`
  0.8, ModelStart, ModelEnd, Score, RowComp, \`
  ColumnComp, AngleComp, ScoreComp, ModelComp)`

**Result**

If the parameters are valid, the operator `create_component_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Module**

Matching
**create_trained_component_model**

```c
create_trained_component_model { : : ComponentTrainingID,
    AngleStart, AngleExtent, MinContrastComp, MinScoreComp,
    NumLevelsComp, AngleStepComp, OptimizationComp, MetricComp,
    PregenerationComp : ComponentModelID, RootRanking }
```

Prepare a component model for matching based on trained components.

`create_trained_component_model` prepares the training result, which is passed in `ComponentTrainingID`, as a component model for matching. The output parameter `ComponentModelID` is a handle for this model, which is used in subsequent calls to `find_component_model`. In contrast to `create_component_model`, the model components must have been previously trained using `train_model_components` before calling `create_trained_component_model`.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations of the component model in an image.

Internally, a separate shape model is built for each model component (see `create_shape_model`). Therefore, the parameters `MinContrastComp`, `MinScoreComp`, `NumLevelsComp`, `AngleStepComp`, `OptimizationComp`, `MetricComp`, and `PregenerationComp` correspond to the parameters of `create_shape_model`, with the following differences: First, the parameter `Optimization` of `create_shape_model` provides the possibility to reduce the number of model points as well as the possibility to completely pregenerate the shape model. In contrast, the operator `create_trained_component_model` uses a separate parameter `PregenerationComp` in order to decide whether the shape models should be completely pregenerated or not. A second difference concerning the parameter `MinScoreComp` should be noted. When using the shape-based matching, this parameter needs not be passed when preparing the shape model using `create_shape_model` but only during the search using `find_shape_model`. In contrast, when preparing the component model it is favorable to analyze rotational symmetries of the model components and similarities between the model components. However, this analysis only leads to meaningful results if the value for `MinScoreComp` that is used during the search (see `find_component_model`) is already approximately known. After the search with `find_component_model` the pose parameters of the components in a search image are returned. Note that the pose parameters refer to the reference points of the components. The reference point of a component is the center of gravity of its associated region that is returned in `ModelComponents` of `train_model_components`.

The parameters `MinContrastComp`, `NumLevelsComp`, `AngleStepComp`, and `OptimizationComp` can be automatically determined by passing `auto` for the respective parameters.

All component-specific input parameters (parameter names terminate with the suffix `Comp`) must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as the number of model components contained in `ComponentTrainingID`, in which case each parameter element refers to the corresponding component in `ComponentTrainingID`.

In addition to the individual shape models, the component model also contains information about the way the single model components must be searched relative to each other using `find_component_model` in order to minimize the computation time of the search. For this, the components are represented in a tree structure. First, the component that stands at the root of this search tree (root component) is searched. Then, the remaining components are searched relative to the pose of their predecessor in the search tree.

The root component can be passed as an input parameter of `find_component_model` during the search. To what extent a model component is suited to act as root component depends on several factors. In principle, a model component that can be found in the image with a high probability should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as root component. Additionally, the computation time that is associated with the root component during the search can serve as a criterion. A ranking of the model components that is based on the latter criterion is returned in `RootRanking`. In this parameter the indices of the model components are sorted in descending order according to their associated computation time, i.e., `RootRanking[0]` contains the index of the model component that, chosen as root component, allows the fastest search. Note that the ranking returned in `RootRanking` represents only a coarse estimation. Furthermore, the calculation of the root ranking assumes that the image size as well as the value of the system parameter `border_shape_models` are identical when calling `create_trained_component_model` and `find_component_model`.

---

Parameters

- **ComponentTrainingID** (input_control) .........................component_training ~ handle
  Handle of the training result.
18.1. COMPONENT-BASED

- **AngleStart** (input_control) .............................. angle.rad \sim real
  Smallest rotation of the component model.
  Default value: -0.39
  Suggested values: \( \text{AngleStart} \in [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0] \)

- **AngleExtent** (input_control) .............................. angle.rad \sim real
  Extent of the rotation of the component model.
  Default value: 0.79
  Suggested values: \( \text{AngleExtent} \in [6.28, 3.14, 1.57, 0.79, 0.39] \)
  Restriction: \( \text{AngleExtent} \geq 0 \)

- **MinContrastComp** (input_control) ........................ integer(-array) \sim integer / string
  Minimum contrast of the components in the search images.
  Default value: 'auto'
  Suggested values: \( \text{MinContrastComp} \in \{\text{'auto'}, 10, 20, 40\} \)
  Restriction: \( \text{MinContrastComp} \geq 0 \)

- **MinScoreComp** (input_control) .............................. real(-array) \sim real
  Minimum score of the instances of the components to be found.
  Default value: 0.5
  Suggested values: \( \text{MinScoreComp} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: \( 0 \leq \text{MinScoreComp} \leq 1 \)

- **NumLevelsComp** (input_control) ........................ integer(-array) \sim integer / string
  Maximum number of pyramid levels for the components.
  Default value: 'auto'
  List of values: \( \text{NumLevelsComp} \in \{\text{'auto'}, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\} \)

- **AngleStepComp** (input_control) .............................. angle.rad(-array) \sim real / string
  Step length of the angles (resolution) for the components.
  Default value: 'auto'
  Suggested values: \( \text{AngleStepComp} \in \{\text{'auto'}, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\} \)
  Restriction: \( \text{AngleStepComp} \geq 0 \)

- **OptimizationComp** (input_control) ........................ string \sim string
  Kind of optimization for the components.
  Default value: 'auto'
  List of values: \( \text{OptimizationComp} \in \{\text{'auto'}, \text{'none'}, \text{'point_reduction_low'}, \text{'point_reduction_medium'}, \text{'point_reduction_high'}\} \)

- **MetricComp** (input_control) .............................. string(-array) \sim string
  Match metric used for the components.
  Default value: 'use_polarity'
  List of values: \( \text{MetricComp} \in \{\text{'use_polarity'}, \text{'ignore_global_polarity'}, \text{'ignore_local_polarity'}, \text{'ignore_color_polarity'}\} \)

- **PregenerationComp** (input_control) ........................ string(-array) \sim string
  Complete pregeneration of the shape models for the components if equal to 'true'.
  Default value: 'false'
  List of values: \( \text{PregenerationComp} \in \{\text{'true'}, \text{'false'}\} \)

- **ComponentModelID** (output_control) ........................ component_model \sim handle
  Handle of the component model.

- **RootRanking** (output_control) .............................. integer(-array) \sim integer
  Ranking of the model components expressing the suitability to act as the root component.

---

Example

* Get the model image.
  read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)  
  gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)  
  gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)  
  gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)

* Get the training images.
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor

* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, \%
    TrainingImages, ModelComponents, 22, 60, 30, 0.65, \%
    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \%
    ComponentTrainingID)

* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, \%
    0.5, 'auto', 'auto', 'none', \%
    'use_polarity', 'false', ComponentModelID, \%
    RootRanking)

* Find the component model in a run-time image.
read_image (SearchImage, 'search_image.tif')
find_component_model (SearchImage, ComponentModelID, RootRanking, -rad(30), \%
    rad(60), 0.5, 0.5, 'stop_search', 'prune_branch', \%
    'none', 0.55, 'least_squares', 0, 0.9, ModelStart, \%
    ModelEnd, Score, RowComp, ColumnComp, AngleComp, \%
    ScoreComp, ModelComp)

Result

If the parameters are valid, the operator create_trained_component_model returns the value 2
(H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific
operators even though the handle is used as an input parameter by those operators.

Module

Matching

find_component_model ( Image : : ComponentModelID, RootComponent, AngleStartRoot, AngleExtentRoot, MinScore, NumMatches, MaxOverlap, IfRootNotFound, IfComponentNotFound, PosePrediction, MinScoreComp, SubPixelComp, NumLevelsComp, GreedinessComp : ModelStart, ModelEnd, Score, RowComp, ColumnComp, AngleComp, ScoreComp, ModelComp )

Find the best matches of a component model in an image.

The operator find_component_model finds the best NumMatches instances of the component model ComponentModelID in the input image Image.

The result of the search can be visualized using get_found_component_model. Also the operator can be used to extract the component matches of a certain component model instance.

Further information about input parameters

ComponentModelID: Handle of the component model.

The model must have been created previously by calling create_trained_component_model or create_component_model, or read in using read_component_model.

RootComponent: Index of the root component.

The components of the component model ComponentModelID are represented in in a tree structure. The component that stands at the root of this search tree is the root component.

The root component is searched within the full search space, i.e., at all allowed positions and in the allowed range of orientations (see below). In contrast, the remaining components are searched relative to the pose of their predecessor in the search tree within a restricted search space that is computed from the relations (recursive search).

To what extent a model component is suited to act as root component depends on several factors. In principle, a model component that can be found in the image with a high probability, should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as root component. For the behavior in such cases, see the entry IfRootNotFound below.

A different possible criterion is the computation time that is associated with the root component during the search. A ranking of the model components that is based on the latter criterion is returned in RootRanking of the operator create_trained_component_model or create_component_model, respectively. If the complete ranking is passed in RootComponent, the first value RootComponent[0] is automatically selected as the root component.

AngleStartRoot and AngleExtentRoot: Specify the allowed angle range (in [rad]) within which the root component is searched.

If necessary, the range of rotations is clipped to the range given when the component model was created with create_trained_component_model or create_component_model, respectively. The angle range for each component can be queried with get_shape_model_params. The necessary handle of the corresponding shape model can be obtained using get_component_model_params.

MinScore: Determines what score a potential match of the component model must at least have to be regarded as an instance.

If the component model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. The value of this parameter only slightly influences the computation time. An exception is the case of IfRootNotFound set to 'select_new_root' (see below).

NumMatches: Determines the maximum number of returned instances.

If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. In case more than NumMatches instances with a score greater than
MinScore are found in the image, only the best NumMatches instances are returned. However, if all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

MaxOverlap: Determines by what fraction two instances may at most overlap, whereby this fraction is a number between 0 and 1.

In some cases, found instances only differ in the pose of one or a few components. If two instances overlap each other by more than MaxOverlap only the best instance is returned. This means, for MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 no check for overlap is performed, and hence all instances are returned. The calculation of the overlap is based on the smallest enclosing rectangles of arbitrary orientation (see smallest_rectangle2) of the found component instances.

IfRootNotFound: specifies the behavior of the operator when dealing with a missing or strongly occluded root component.

Possible values:
- 'stop_search': It is assumed that the root component is always found in the image. Consequently, for instances for which the root component could not be found the search for the remaining components is not continued.
- 'select_new_root': Different components are successively chosen as the root component and searched within the full search space. The order in which the selection of the root component is performed corresponds to the order passed in RootRanking. The poses of the found instances of all root components are then used to start the recursive search for the remaining components. Hence, it is possible to find instances even if the original root component is not found. However, the computation time of the search increases significantly in comparison to the search when choosing 'stop_search'. This is especially the case for small values of MinScore, as more root components must be searched. If during the search more root components are needed as given in RootComponent, the root components are completed by the automatically computed order (see create_trained_component_model or create_component_model).

IfComponentNotFound: Specifies how components are searched when the predecessor component was not found (e.g., because she is missing or strongly occluded).

Possible values:
- 'prune_branch': Such components are not searched at all and are also treated as 'not found'.
- 'search_from_upper': Such components are searched relative to the pose of the predecessor component of the predecessor component.
- 'search_from_best': Such components are searched relative to the pose of the already found component from which the relative search can be performed with minimum computational effort.

PosePrediction: Determines whether the pose of not found components should be estimated.

Possible values:
- 'none': Only the poses of the found components are returned.
- 'from_neighbors': The poses of not found components are estimated and returned with a score of ScoreComp = 0.0. The pose estimation is based on the poses of the found neighboring components in the search tree.
- 'from_all': The poses of not found components are estimated and returned with a score of ScoreComp = 0.0. The pose estimation is based on the poses of all found components.

MinScoreComp: Minimal necessary score of the components for the instances to be found.

This parameter has the same meaning as MinScore in find_shape_model. Settable is either one element or the same number of elements as model components in ComponentModelID. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in ComponentModelID.

SubPixelComp: Determines whether the extraction shall be done subpixel precise and in the given case the maximal allowed object deformation in pixels.

This parameter has the same meaning as SubPixel in find_shape_model. Therefore the maximal allowed object deformation has to be given as integer in the same string. Settable is either one element or the same number of elements as model components in ComponentModelID. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in ComponentModelID.

Example: ['least_squares', 'max_deformation 2'].

HALCON 20.05.0.0
**NumLevelsComp**: Determine the pyramid levels for the components used in the matching.

This parameter has the same meaning as NumLevels in `find_shape_model`.

It determines the number of pyramid levels for the components to be used in the matching. Settable is either one element or the same number of elements as model components in `ComponentModelID`. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in `ComponentModelID`.

Optional, one can set value pairs for this parameter: In this case, the first value still determines the number of pyramid levels to be used. The second value specifies the lowest pyramid level, to which the found matches are tracked. In doing so, one can set either a single value pair or a value pair for each model component in `ComponentModelID`. If different value pairs should be used for different components, they must be specified in the same tuple. In case `ComponentModelID` contains exactly two components and in `NumLevelsComp` two values are set, these values are interpreted as different number of pyramid levels to be used and not as a value pair.

*Example*: `ComponentModelID` contains two components, for which different pyramid levels shall be considered. For the first component 5 levels up to the level 2 shall be used. For the second component 4 levels up to the level 1 shall be used. In this case is `NumLevelsComp = [5,2,4,1]`.

**GreedinessComp**: “Greediness” of the search heuristic for the components: value from 0 to 1. Thereby 0 means: safe but slow, 1: fast but matches may be missed.

This parameter has the same meaning as `Greediness` in `find_shape_model`.

Settable is either one element or the same number of elements as model components in `ComponentModelID`. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in `ComponentModelID`.

Further information about output parameters

**ModelStart** and **ModelEnd**: Return the first and last index and therewith the index range of all component matches associated to the same instance of the component model.

The component matches corresponding to the first found instance of the component model are given by the interval of indices `[ModelStart[0], ModelEnd[0]]`. Thereby the indices refer to the values of the parameters `RowComp, ColumnComp, AngleComp, ScoreComp, and ModelComp`.

*Example*: The component model consists for three components. Two instances have been found on the image, where for one instance only two components (component 0 and component 2) could be found. Then the returned parameters could look like this:

```
RowComp = [100,200,300,150,250]   ModelStart = [0,3]
AngleComp = [0,0.1,-0.2,0.1,0.2]   ModelComp = [0,1,2,0,2]
ScoreComp = [1,1,1,1,1]            Score = [1,1]
```

From the right column it is visible, that in the left column:

- Values with index 0 to 2 correspond to the components 0 to 2 of instance 1.
- Values with index 3 to 4 correspond to the components 0 and 2 of instance 2.

**Score**: Score of the found instances of the component model.

`Score` contains the weighted mean of the component scores, the values in `ScoreComp`. The weighting is performed according to the number of model points within the respective component.

**RowComp, ColumnComp, and AngleComp**: The position (`RowComp`, `ColumnComp`) and rotation (`AngleComp`) of the model components of all found component model instances.

The coordinates `RowComp` and `ColumnComp` are the coordinates of the component origin (reference point) in the search image. The component origin depends on the model creation:

- with `create_trained_component_model` by training: The component origin is the center of gravity of the respective returned contour region in `ModelComponents` of the operator `train_model_components`.
- with `create_component_model` manually: The component origin is the center of gravity of the corresponding passed component region `ComponentRegion` of the operator `create_component_model`.
Since the relations between the components in ComponentModelID refer to this reference point, the origin of the components must not be modified by using set_shape_model_origin.

**ScoreComp**: Score of each found component instance.

The score is a number between 0 and 1, and is an approximate measure of how much of the component is visible in the image. If, for example, half of the component is occluded, the score cannot exceed 0.5.

**ModelComp**: Index of the found component.

The tuple contains the indices of the respective model components (see create_component_model and train_model_components, respectively). By this the values in RowComp, ColumnComp, AngleComp, and ScoreComp can be associated to the different model components. See also the example given for ModelStart and ModelEnd.

**Information concerning the search**

Internally, the shape-based matching is used for the component-based matching in order to search the individual components (see find_shape_model).

The domain of the Image determines the search space for the reference point, i.e., the allowed positions, of the root component.

Usually the component model is searched only within those points of the image domain in which the model fits completely into the image. This means that the components will not be found if they extend beyond the borders of the image, even if they would achieve a score greater than MinScoreComp (see above).

Note that, if for a certain pyramid level the component model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with set_system (‘border_shape_models’, ‘true’), which will cause components that extend beyond the image border to be found if they achieve a score greater than MinScoreComp. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that this mode increases the runtime of the search.

Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., dilation_circle.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.

**Recommendations**

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a subpixel extraction that applies a least-squares adjustment. If the subpixel extraction and/or the maximum object deformation is specified separately for each component, for each component in ComponentModelID exactly one value for the subpixel extraction must be passed in SubPixelComp. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain component no value for the maximum object deformation is passed, the component is searched without taking deformations into account. Further details can be found in the documentation of find_shape_models.

---

**Parameters**

- **Image** (input_object) \(\text{(multichannel-)image} \sim \text{object : byte / uint2}

Input image in which the component model should be found.

- **ComponentModelID** (input_control) \(\text{component_model} \sim \text{handle}

Handle of the component model.

- **RootComponent** (input_control) \(\text{integer(-array)} \sim \text{integer}

Index of the root component.

**Suggested values**: RootComponent \(\in \{0, 1, 2, 3, 4, 5, 6, 7, 8\}\)
AngleStartRoot (input_control) angle.rad(-array) ⇒ real
Smallest rotation of the root component
Default value: -0.39
Suggested values: AngleStartRoot ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

AngleExtentRoot (input_control) angle.rad(-array) ⇒ real
Extent of the rotation of the root component.
Default value: 0.79
Suggested values: AngleExtentRoot ∈ {6.28, 3.14, 1.57, 0.79, 0.39, 0.0}
Restriction: AngleExtentRoot ≥ 0

MinScore (input_control) real ⇒ real
Minimum score of the instances of the component model to be found.
Default value: 0.5
Suggested values: MinScore ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 ≤ MinScore && MinScore ≤ 1

NumMatches (input_control) integer ⇒ integer
Number of instances of the component model to be found (or 0 for all matches).
Default value: 1
Suggested values: NumMatches ∈ {0, 1, 2, 3, 4, 5, 10, 20}

MaxOverlap (input_control) real ⇒ real
Maximum overlap of the instances of the component models to be found.
Default value: 0.5
Suggested values: MaxOverlap ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 ≤ MaxOverlap && MaxOverlap ≤ 1

IfRootNotFound (input_control) string ⇒ string
Behavior if the root component is missing.
Default value: 'stop_search'
List of values: IfRootNotFound ∈ {'stop_search', 'select_new_root'}

IfComponentNotFound (input_control) string ⇒ string
Behavior if a component is missing.
Default value: 'prune_branch'
List of values: IfComponentNotFound ∈ {'prune_branch', 'search_from_upper', 'search_from_best'}

PosePrediction (input_control) string ⇒ string
Pose prediction of components that are not found.
Default value: 'none'
List of values: PosePrediction ∈ {'none', 'from_neighbors', 'from_all'}

MinScoreComp (input_control) real(-array) ⇒ real
Minimum score of the instances of the components to be found.
Default value: 0.5
Suggested values: MinScoreComp ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 ≤ MinScoreComp && MinScoreComp ≤ 1

SubPixelComp (input_control) string(-array) ⇒ string
Subpixel accuracy of the component poses if not equal to 'none'.
Default value: 'least_squares'
Suggested values: SubPixelComp ∈ {'none', 'interpolation', 'least_squares', 'least_squares_high',
'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3',
'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}

NumLevelsComp (input_control) integer(-array) ⇒ integer
Number of pyramid levels for the components used in the matching (and lowest pyramid level to use if
|NumLevelsComp| = 2n).
Default value: 0
List of values: NumLevelsComp ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
18.1. COMPONENT-BASED

- **GreedinessComp** (input_control) ........................................... real(-array) $\sim$ real
  “Greediness” of the search heuristic for the components (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: GreedinessComp $\in\{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: $0 \leq$ GreedinessComp $\&\&$ GreedinessComp $\leq 1$

- **ModelStart** (output_control) ............................................. integer(-array) $\sim$ integer
  Start index of each found instance of the component model in the tuples describing the component matches.

- **ModelEnd** (output_control) ................................................ integer(-array) $\sim$ integer
  End index of each found instance of the component model in the tuples describing the component matches.

- **Score** (output_control) .................................................. real(-array) $\sim$ real
  Score of the found instances of the component model.

- **RowComp** (output_control) ............................................... point.y(-array) $\sim$ real
  Row coordinate of the found component matches.

- **ColumnComp** (output_control) ........................................... point.x(-array) $\sim$ real
  Column coordinate of the found component matches.

- **AngleComp** (output_control) ............................................ angle.rad(-array) $\sim$ real
  Rotation angle of the found component matches.

- **ScoreComp** (output_control) ............................................ real(-array) $\sim$ real
  Score of the found component matches.

- **ModelComp** (output_control) ........................................... integer(-array) $\sim$ integer
  Index of the found components.

If the parameter values are correct, the operator find_component_model returns the value 2
(H_MSG_TRUE). If the input is empty (no input image available) the behavior can be set via set_system
(‘no_object_result’,<Result>). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**gen_initial_components**

```plaintext
ModelImage : InitialComponents : ContrastLow, ContrastHigh,
MinSize, Mode, GenericName, GenericValue : )
```

Extract the initial components of a component model.

In general, there are two possibilities to use gen_initial_components. The first possibility should be
chosen if the components of the component model are not known. Then gen_initial_components

HALCON 20.05.0.0
automatically extracts the initial components of a component model from a model image. The second possibility can be chosen if the components of the component model are approximately known. Then \texttt{gen\_initial\_components} can be used to find suitable parameter values for the model feature extraction in \texttt{train\_model\_components} and \texttt{create\_component\_model}. Hence, the second possibility is comparable to the function of \texttt{inspect\_shape\_model} within the shape-based matching.

When using the first possibility, \texttt{gen\_initial\_components} extracts the initial components of a component model from a model image \texttt{ModelImage}. As already mentioned, this is especially useful if the components of the component model are not known. In this case, the resulting initial components can be used to automatically train the component model with \texttt{train\_model\_components}, which extracts the (final) model components and the relations between them. \texttt{gen\_initial\_components} returns the initial components in a region object tuple \texttt{InitialComponents} that contains a representation for each initial component in form of contour regions.

For the automatic determination of the initial components, the domain of the model image \texttt{ModelImage} must contain the entire compound object including all components. \texttt{Mode} specifies the method used for the automatic computation. Currently, only the mode \texttt{connection} is available. In this mode the automatic computation is performed in two steps: In the first step, features are extracted using the parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize}. These three parameters define the contours of which the initial components should consist and should be chosen such that only the significant features of the model image are contained in the initial components. \texttt{ContrastLow} and \texttt{ContrastHigh} specify the gray value contrast of the points that should be contained in the initial components. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. The model image is segmented using a method similar to the hysteresis threshold method used in \texttt{edges\_image}. Here, \texttt{ContrastLow} determines the lower threshold, while \texttt{ContrastHigh} determines the upper threshold. If the same value is passed for \texttt{ContrastLow} and \texttt{ContrastHigh} a simple thresholding operation is performed. For more information about the hysteresis threshold method, see \texttt{hysteresis\_threshold}. \texttt{MinSize} can be used to select only significant features for the initial components based on the size of the connected contour regions, i.e., connected contour regions with fewer than \texttt{MinSize} points are suppressed.

The resulting connected contour regions are iteratively merged in the second step. For this, two contour regions are merged if the distance between both regions is smaller than a certain threshold (see below). Finally, the merged regions are returned in \texttt{InitialComponents} and can be used to train the component model by passing them to \texttt{train\_model\_components}.

To control the internal image processing, the parameters \texttt{GenericName} and \texttt{GenericValue} are used. This is done by passing the names of the control parameters to be changed in \texttt{GenericName} as a list of strings. In \texttt{GenericValue} the values are passed at the corresponding index positions.

Normally, none of the values needs to be changed. A change should only be applied in case of unsatisfying results of the automatic determination of the initial components. The two parameters that can be changed are \texttt{merge\_distance} and \texttt{merge\_fraction}; both are used during the iterative merging of contour regions (see above). First, the fraction of contour pixels of one contour region that at most have a distance of \texttt{merge\_distance} from another contour region is computed. If this fraction exceeds the value that is passed in \texttt{merge\_fraction} the two contour regions are merged. Consequently, the higher \texttt{merge\_distance} and the lower \texttt{merge\_fraction} is chosen the more contour regions are merged. The default value of \texttt{merge\_distance} is 5 and the default value of \texttt{merge\_fraction} is 0.5 (corresponds to 50 percent).

When using the second possibility, i.e., the components of the component model are approximately known, the training by using \texttt{train\_model\_components} can be performed without previously executing \texttt{gen\_initial\_components}. If this is desired, the initial components can be specified by the user and directly passed to \texttt{train\_model\_components}. Furthermore, if the components as well as the relative movements (relations) of the components are known, \texttt{gen\_initial\_components} as well as \texttt{train\_model\_components} need not be executed. In fact, by immediately passing the components as well as the relations to \texttt{create\_component\_model}, the component model can be created without any training. In both cases, however, \texttt{gen\_initial\_components} can be used to evaluate the effect of the feature extraction parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize} of \texttt{train\_model\_components} and \texttt{create\_component\_model}, and hence to find suitable parameter values for a certain application.

For this, the image regions for the (initial) components must be explicitly given, i.e., for each (initial) component a separate image from which the (initial) component should be created is passed. In this case, \texttt{ModelImage} contains multiple image objects. The domain of each image object is used as the region of interest for calculating the corresponding (initial) component. The image matrix of all image objects in the tuple must be identical, i.e., \texttt{ModelImage} cannot be constructed in an arbitrary manner using \texttt{concat\_obj}, but must be created from the same image using \texttt{add\_channels} or equivalent calls. If this is not the case, an error message is returned. If
the parameters ContrastLow, ContrastHigh, or MinSize only contain one element, this value is applied to the creation of all (initial) components. In contrast, if different values for different (initial) components should be used, tuples of values can be passed for these three parameters. In this case, the tuples must have a length that corresponds to the number of (initial) components, i.e., the number of image objects in ModelImage. The contour regions of the (initial) components are returned in InitialComponents.

Thus, the second possibility is equivalent to the function of inspect_shape_model within the shape-based matching. However, in contrast to inspect_shape_model, gen_initial_components does not return the contour regions on multiple image pyramid levels. Therefore, if the number of pyramid levels to be used should be chosen manually, preferably inspect_shape_model should be called individually for each (initial) component.

For both described possibilities the parameters ContrastLow, ContrastHigh, and MinSize can be automatically determined. If both hysteresis threshold should be automatically determined, both ContrastLow and ContrastHigh must be set to ‘auto’. In contrast, if only one threshold value should be determined, ContrastLow must be set to ‘auto’ while ContrastHigh must be set to an arbitrary value different from ‘auto’.

If the input image ModelImage has one channel the representation of the model is created with the method that is used in create_component_model or create_trained_component_model for the metrics ‘use_polarity’, ‘ignore_global_polarity’, and ‘ignore_local_polarity’. If the input image has more than one channel the representation is created with the method that is used for the metric ‘ignore_color_polarity’.

Parameters

▷ ModelImage (input_object) ..............................................(multichannel-)image(-array)  ~ object : byte / uint2
  Input image from which the initial components should be extracted.

▷ InitialComponents (output_object) ..............................region-array  ~ object
  Contour regions of initial components.

▷ ContrastLow (input_control) ....................................integer(-array)  ~ integer / string
  Lower hysteresis threshold for the contrast of the initial components in the image.
  Default value: ‘auto’
  Suggested values: ContrastLow ∈ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
  Restriction: ContrastLow > 0

▷ ContrastHigh (input_control) ....................................integer(-array)  ~ integer / string
  Upper hysteresis threshold for the contrast of the initial components in the image.
  Default value: ‘auto’
  Suggested values: ContrastHigh ∈ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
  Restriction: ContrastHigh > 0 && ContrastHigh >= ContrastLow

▷ MinSize (input_control) ..........................................integer(-array)  ~ integer / string
  Minimum size of the initial components.
  Default value: ‘auto’
  Suggested values: MinSize ∈ {'auto’, 0, 5, 10, 20, 30, 40}
  Restriction: MinSize >= 0

▷ Mode (input_control) ...............................................string  ~ string
  Type of automatic segmentation.
  Default value: ‘connection’
  List of values: Mode ∈ {'connection’}

▷ GenericName (input_control) ....................................string(-array)  ~ string
  Names of optional control parameters.
  Default value: []
  List of values: GenericName ∈ {'merge_distance’, ‘merge_fraction’}

▷ GenericValue (input_control) ....................................number(-array)  ~ real / integer
  Values of optional control parameters.
  Default value: []

Example

* First example that shows the use of gen_initial_components to automatically extract the initial components from a model image.

* Get the model image.
* Define the entire model region.
  
  `gen_rectangle1(ModelRegion, 119, 106, 330, 537)`

* Automatically generate the initial components.
  
  `gen_initial_components(ModelImage, InitialComponents, 40, 40, 20, \ 'connection', [], [])`

* Extract the model components and train the relations.
  
  `train_model_components(ModelImage, InitialComponents, TrainingImages, \  ModelComponents, 40, 40, 20, 0.85, 0, 0, rad(15), \  'speed', 'rigidity', 0.2, 0.5, ComponentTrainingID)`

* Create the component model based on the training result.
  
  `create_trained_component_model(ComponentTrainingID, -rad(30), rad(60), 10, \  0.8, 'auto', 'auto', 'none', \  'use_polarity', 'false', ComponentModelID, \  RootRanking)`

* Second example that shows the use of `gen_initial_components` to evaluate
  * the effect of the feature extraction parameters.

* Get the model image.
  
  `read_image(ModelImage, 'model_image.tif')`

* Define the regions for the components.
  
  `gen_rectangle2(ComponentRegions, 318, 109, -1.62, 34, 19)`
  
  `gen_rectangle2(Rectangle2, 342, 238, -1.63, 32, 17)`
  
  `gen_rectangle2(Rectangle3, 355, 505, 1.41, 25, 17)`
  
  `concat_obj(ComponentRegions, Rectangle2, ComponentRegions)`
  
  `concat_obj(ComponentRegions, Rectangle3, ComponentRegions)`
  
  `add_channels(ComponentRegions, ModelImage, ModelImageReduced)`
  
  `gen_initial_components(ModelImageReduced, InitialComponents, 15, 40, 15, \  'connection', [], [])`

* Create the component model by explicitly specifying the relations.
  
  `create_component_model(ModelImage, ComponentRegions, 20, 20, rad(25), 0, \  rad(360), 15, 40, 15, 10, 0.8, 'auto', 'auto', \  'none', 'use_polarity', 'false', ComponentModelID, \  RootRanking)`

---

**Result**

If the parameter values are correct, the operator `gen_initial_components` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system` (‘no_object_result’,<Result>). If necessary, an exception is raised.

---

**Parallelization**

**Module**

Matching
Return the parameters of a component model.

The operator `get_component_model_params` returns the parameters of the component model `ComponentModelID`. In particular, this output can be used to check the parameters `RootRanking` and `MinScoreComp` after reading the component model with `read_component_model`. Additionally, the operator returns the shape model IDs `ShapeModelIDs` of the model components. The order of the returned shape model IDs corresponds to the indices of the components within the component model `ComponentModelID`. The IDs can be used to query their shape model parameters with `get_shape_model_params`.

**Parameters**

- `ComponentModelID` (input_control), component_model `.handle`
  - Handle of the component model.
- `MinScoreComp` (output_control), MinScoreComp `real(-array)`
  - Minimum score of the instances of the components to be found.
- `RootRanking` (output_control), RootRanking `integer(-array)`
  - Ranking of the model components expressing their suitability to act as root component.
- `ShapeModelIDs` (output_control), ShapeModelIDs `shape_model(-array)`
  - Handles of the shape models of the individual model components.

**Example**

```plaintext
read_component_model ('pliers.cpm', ComponentModelID)
get_component_model_params (ComponentModelID, MinScoreComp, RootRanking, \\
 ShapeModelIDs)
for i := 0 to |ShapeModelIDs|-1 by 1
  get_shape_model_params (ShapeModelIDs[i], NumLevels, AngleStart, \\
  AngleExtent, AngleStep, ScaleMin, ScaleMax, \\
  ScaleStep, Metric, MinContrast)
endfor
```

**Result**

If the handle of the component model is valid, the operator `get_component_model_params` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

\[
\text{get_component_model_tree} ( : \ Tree, Relations : \ ComponentModelID, \\
RootComponent, Image : \ StartNode, EndNode, Row, Column, Phi, \\
Length1, Length2, AngleStart, AngleExtent )
\]

Return the search tree of a component model.
get_component_model_tree returns the search tree \textit{Tree} and the associated relations \textit{Relations} of the component model that is passed in \textit{ComponentModelID} in form of regions as well as in numerical form. \textit{get_component_model_tree} is particularly useful in order to visualize the search order of the components, which was automatically computed in \textit{create_trained_component_model} or \textit{create_component_model}.

Because the search tree depends on the selected root component, the root component must be passed in \textit{RootComponent}. The nodes in the tree \textit{Tree} represent the model components, the connecting lines between the nodes indicate which components are searched relative to each other. The position of the nodes corresponds to the position of the components in the model image (if \textit{Image} = 'model_image' or \textit{Image} = 0) or in a training image (if \textit{Image} \geq 1). In the latter case, the component model must have been created based on a component training result with \textit{create_trained_component_model}.

Let \( n \) be the number of components in \textit{ComponentModelID}. The region object tuple \textit{Relations} of length \( n \) is designed as follows: For each component a separate region is returned. The positions of all components in the image are represented by circles with a radius of 3 pixels. For each component other than the root component \textit{RootComponent}, additionally the position relation and the orientation relation relative to the predecessor component in the search tree are represented. The position relation is represented by a rectangle, the orientation relation is represented by a circle sector with a radius of 30 pixels. The center of the circle is placed at the mean relative position of the component. The rectangle describes the movement of the reference point of the respective component relative to the pose of its predecessor component, the circle sector describes the variation of the relative orientation. A relative orientation of 0 corresponds to the relative orientation of both components in the model image.

In addition to the regions, the search tree as well as the associated relations are also returned in numerical form. The search tree is described by the two tuples \textit{StartNode} and \textit{EndNode}, both of length \( n \), which contain the start and the end node of all arcs in the tree. The nodes contain the indices of the components. This means that during the search the component that is described by the end node is searched relative to the pose of the component that is described by the start node (predecessor component). Since the root component is not searched relative to any other component, and hence does not have a predecessor component, the associated start node is set to -1. The relations are returned in \textit{Row}, \textit{Column}, \textit{Phi}, \textit{Length1}, \textit{Length2}, \textit{AngleStart}, and \textit{AngleExtent}. These parameters are tuples of length \( n \), and contain the relations of all components relative to their associated predecessor component, where the order of the values within the tuples is determined by the index of the corresponding component. The position relation is described by the parameters of the corresponding rectangle \textit{Row}, \textit{Column}, \textit{Phi}, \textit{Length1}, and \textit{Length2} (see \textit{gen_rectangle2}). The orientation relation is described by the starting angle \textit{AngleStart} and the angle extent \textit{AngleExtent}.

For the root component as well as for components that do not have a predecessor in the current image or that have not been found in the current image, an empty region is returned and the corresponding values of the seven parameters are set to 0.

\begin{verbatim}
Parameters
\end{verbatim}

\begin{itemize}
\item \textit{Tree} (output_object) .................................................. region \sim object Search tree.
\item \textit{Relations} (output_object) ........................................... region-array \sim object Relations of components that are connected in the search tree.
\item \textit{ComponentModelID} (input_control) .......................... component_model \sim handle Handle of the component model.
\item \textit{RootComponent} (input_control) ................................. integer(-array) \sim integer Index of the root component.
\item \textit{Image} (input_control) ............................................. string \sim string/int Image for which the tree is to be returned.
\item \textit{StartNode} (output_control) ...................................... integer(-array) \sim integer Component index of the start node of an arc in the search tree.
\item \textit{EndNode} (output_control) ...................................... integer(-array) \sim integer Component index of the end node of an arc in the search tree.
\item \textit{Row} (output_control) ............................................ rectangle2.center.y(-array) \sim real Row coordinate of the center of the rectangle representing the relation.
\end{itemize}
18.1. COMPONENT-BASED

- **Column** (output_control) \( \rightarrow \) real
  
  Column index of the center of the rectangle representing the relation.

- **Phi** (output_control) \( \rightarrow \) real
  
  Orientation of the rectangle representing the relation (radians).
  
  **Assertion:** \(-\pi / 2 < \Phi \&\& \Phi <= \pi / 2\)

- **Length1** (output_control) \( \rightarrow \) real
  
  First radius (half length) of the rectangle representing the relation.
  
  **Assertion:** \(Length1 >= 0.0\)

- **Length2** (output_control) \( \rightarrow \) real
  
  Second radius (half width) of the rectangle representing the relation.
  
  **Assertion:** \(Length2 >= 0.0 \&\& Length2 <= Length1\)

- **AngleStart** (output_control) \( \rightarrow \) real
  
  Smallest relative orientation angle.

- **AngleExtent** (output_control) \( \rightarrow \) real
  
  Extent of the relative orientation angle.

---

**Example**

* Read the model image.
  
  `read_image (ModelImage, 'model_image.tif')`

* Describe the model components.
  
  `gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)`
  `gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)`
  `gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)`
  `concat_obj (ComponentRegions, Rectangle2, ComponentRegions)`
  `concat_obj (ComponentRegions, Rectangle3, ComponentRegions)`

* Create the component model.
  
  `create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \`
  "rad(360), 15, 40, 15, 10, 0.8, 0, 0, 'none', "
  '; "use_polarity', 'true', ComponentModelID, \`
  "RootRanking)"

* Get the component model tree.
  
  `get_component_model_tree (Tree, Relations, ComponentModelID, RootRanking, \`
  "model_image', StartNode, EndNode, Row, Column, \`
  "Phi, Length1, Length2, AngleStart, AngleExtent)"

  `dev_set_colored (12)`
  `dev_display (ModelImage)`
  `dev_display (Tree)`
  `dev_display (Relations)`

---

**Result**

If the parameters are valid, the operator `get_component_model_tree` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

HALCON 20.05.0.0
get_component_relations ( : Relations : ComponentTrainingID, 
ReferenceComponent, Image : Row, Column, Phi, Length1, Length2, 
AngleStart, AngleExtent )

Return the relations between the model components that are contained in a training result.

go to the relations between model components after training them with 

\( \text{train_model_components} \). With the parameter \( \text{ReferenceComponent} \), you can select a reference 

\( \text{get_component_relations} \) then returns the relations between the reference component and 

all other components in the model image (if \( \text{Image} = \text{’model_image’} \) or \( \text{Image} = 0 \)) or in a training image 

(if \( \text{Image} \geq 1 \)). In order to obtain the relations in the \( i \)th training image, \( \text{Image} \) must be set to \( i \). The 

result of the training returned by \( \text{train_model_components} \) must be passed in \( \text{ComponentTrainingID} \). 

\( \text{ReferenceComponent} \) describes the index of the reference component and must be within the range of 0 and 
n-1, if \( n \) is the number of model components (see \( \text{train_model_components} \)).

The relations are returned in form of regions in \( \text{Relations} \) as well as in form of numerical values in \( \text{Row} \), 

\( \text{Column} \), \( \text{Length1} \), \( \text{Length2} \), \( \text{AngleStart} \), and \( \text{AngleExtent} \).

The region object tuple \( \text{Relations} \) is designed as follows. For each component a separate region is returned. 

Consequently, \( \text{Relations} \) contains \( n \) regions, where the order of the regions within the tuple is determined by 

the index of the corresponding components. The positions of all components in the image are represented by circles 

with a radius of 3 pixels. For each component other than the reference component \( \text{ReferenceComponent} \), ad-

ditionally the position relation and the orientation relation relative to the reference component are represented. 

The position relation is represented by a rectangle and the orientation relation is represented by a circle sector 

with a radius of 30 pixels. The center of the circle is placed at the mean relative position of the compo-

nent. The rectangle describes the movement of the reference point of the respective component relative to the 
pose of the reference component, while the circle sector describes the variation of the relative orientation (see 

\( \text{train_model_components} \)). A relative orientation of 0 corresponds to the relative orientation of both com-

ponents in the model image. If both components appear in the same relative orientation in all images, the circle 

sector consequently degenerates to a straight line.

In addition to the region object tuple \( \text{Relations} \), the relations are also returned in form of numerical values in 

\( \text{Row} \), \( \text{Column} \), \( \text{Phi} \), \( \text{Length1} \), \( \text{Length2} \), \( \text{AngleStart} \), and \( \text{AngleExtent} \). These parameters are tuples 

of length \( n \) and contain the relations of all components relative to the reference component, where the order of 

the values within the tuples is determined by the index of the corresponding component. The position relation 
is described by the parameters of the corresponding rectangle \( \text{Row} \), \( \text{Column} \), \( \text{Phi} \), \( \text{Length1} \), and \( \text{Length2} \) (see 

\( \text{gen_rectangle2} \)). The orientation relation is described by the starting angle \( \text{AngleStart} \) and the angle 

extent \( \text{AngleExtent} \). For the reference component only the position within the image is returned in \( \text{Row} \) and 

\( \text{Column} \). All other values are set to 0.

If the reference component has not been found in the current image, an array of empty regions is returned and the 
corresponding parameter values are set to 0.

The operator \( \text{get_component_relations} \) is particularly useful in order to visualize the result of the training 
that was performed with \( \text{train_model_components} \). With this, it is possible to evaluate the varia-
tions that are contained in the training images. Sometimes it might be reasonable to restart the training with 

\( \text{train_model_components} \) while using a different set of training images.

Parameters

- Relations (output_object) : region(-array) \( \sim \text{object} \)
  Region representation of the relations.
- ComponentTrainingID (input_control) : component_training \( \sim \text{handle} \)
  Handle of the training result.
- ReferenceComponent (input_control) : integer \( \sim \text{integer} \)
  Index of reference component.
  Restriction: ReferenceComponent \( \geq 0 \)
- Image (input_control) : string \( \sim \text{string / integer} \)
  Image for which the component relations are to be returned.
  Default value: ‘model_image’
  Suggested values: \( \text{Image} \in \{ \text{’model_image’}, 0, 1, 2, 3, 4, 5, 6, 7, 8 \} \)
- Row (output_control) : rectangle2.center.y(-array) \( \sim \text{real} \)
  Row coordinate of the center of the rectangle representing the relation.
18.1. COMPONENT-BASED

- **Column** (output_control) \[\text{rectangle2.center.x(array) \sim real}\]
  Column index of the center of the rectangle representing the relation.

- **Phi** (output_control) \[\text{rectangle2.angle.rad(array) \sim real}\]
  Orientation of the rectangle representing the relation (radians).
  **Assertion:** \(-\pi/2 < \Phi \&\& \Phi <= \pi/2\)

- **Length1** (output_control) \[\text{rectangle2.hwidth(array) \sim real}\]
  First radius (half length) of the rectangle representing the relation.
  **Assertion:** \(\text{Length1} \geq 0.0\)

- **Length2** (output_control) \[\text{rectangle2.hheight(array) \sim real}\]
  Second radius (half width) of the rectangle representing the relation.
  **Assertion:** \(\text{Length2} \geq 0.0 \&\& \text{Length2} <= \text{Length1}\)

- **AngleStart** (output_control) \[\text{angle.rad(array)} \sim real\]
  Smallest relative orientation angle.

- **AngleExtent** (output_control) \[\text{angle.rad(array)} \sim real\]
  Extent of the relative orientation angles.

**Result**

If the handle of the training result is valid, the operator `get_component_relations` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**gen_rectangle2**

**Module**

```haskell
get_found_component_model ( : FoundComponents : ComponentModelID, ModelStart, ModelEnd, RowComp, ColumnComp, AngleComp, ScoreComp, ModelComp, ModelMatch, MarkOrientation : RowCompInst, ColumnCompInst, AngleCompInst, ScoreCompInst )
```

Return the components of a found instance of a component model.

`get_found_component_model` returns the components of a found instance of the component model `ComponentModelID` in form of contour regions in `FoundComponents` as well as in numerical form.

The operator `get_found_component_model` is particularly useful in order to visualize the matches that have been obtained by `find_component_model`.

The pose of the returned components corresponds to their pose in the search image as returned by `find_component_model`. Hence, the parameters `ModelStart`, `ModelEnd`, `RowComp`, `ColumnComp`, `AngleComp`, `ScoreComp`, and `ModelComp` must be passed to `get_found_component_model` as they have been returned by `find_component_model`. In `ModelMatch` the index of the found instance of the component model must be passed. Consequently, `ModelMatch` must lie within the range between 0 and \(m-1\), where \(m\) is the number of elements in `ModelStart` and `ModelEnd`, and hence corresponds to the number of found model instances. For example, if the best match should be returned, `ModelMatch` should be set to 0.

When dealing with rotationally symmetric components, one may wish to mark the current orientation of the found component. This can be achieved by setting `MarkOrientation` to `true`. In this case, the contour region of each component is complemented by an arrow at its reference point that points in the reference direction.

HALCON 20.05.0.0
The reference direction of a component is based on the orientation of the component in the model image (see train_model_components or create_component_model) and is represented by an arrow that starts at the reference point and points to the right in the horizontal direction.

For convenience, the pose parameters as well as the score of each component of the found model instance are additionally returned in numerical form in RowCompInst, ColumnCompInst, AngleCompInst, and ScoreCompInst. The four tuples are always of length \( n \), where \( n \) is the number of components in the component model ComponentModelID. If a component could not be found during the search, an empty region is passed in the corresponding element of FoundComponents and the value of the corresponding element in RowCompInst, ColumnCompInst, AngleCompInst, and ScoreCompInst is set to 0.

**Parameters**

- **FoundComponents** (output_object) \( \rightarrow \) object
  
  Found components of the selected component model instance.

- **ComponentModelID** (input_control) \( \rightarrow \) component_model
  
  Handle of the component model.

- **ModelStart** (input_control) \( \rightarrow \) integer
  
  Start index of each found instance of the component model in the tuples describing the component matches.

- **ModelEnd** (input_control) \( \rightarrow \) integer
  
  End index of each found instance of the component model to the tuples describing the component matches.

- **RowComp** (input_control) \( \rightarrow \) point
  
  Row coordinate of the found component matches.

- **ColumnComp** (input_control) \( \rightarrow \) point
  
  Column coordinate of the found component matches.

- **AngleComp** (input_control) \( \rightarrow \) angle
  
  Rotation angle of the found component matches.

- **ScoreComp** (input_control) \( \rightarrow \) real
  
  Score of the found component matches.

- **ModelComp** (input_control) \( \rightarrow \) integer
  
  Index of the found components.

- **ModelMatch** (input_control) \( \rightarrow \) integer
  
  Index of the found instance of the component model to be returned.

- **MarkOrientation** (input_control) \( \rightarrow \) string
  
  Mark the orientation of the components.

  **Default value:** 'false'

  **List of values:** MarkOrientation \( \in \{ 'true', 'false' \} \)

- **RowCompInst** (output_control) \( \rightarrow \) point
  
  Row coordinate of all components of the selected model instance.

- **ColumnCompInst** (output_control) \( \rightarrow \) point
  
  Column coordinate of all components of the selected model instance.

- **AngleCompInst** (output_control) \( \rightarrow \) angle
  
  Rotation angle of all components of the selected model instance.

- **ScoreCompInst** (output_control) \( \rightarrow \) real
  
  Score of all components of the selected model instance.

**Example**

- Read a component model from file.
  
  ```
  read_component_model ('pliers.cpm', ComponentModelID)
  ```

- Find the component model in a run-time image.
  
  ```
  read_image (SearchImage, 'search_image.tif')
  find_component_model (SearchImage, ComponentModelID, RootRanking, 0, \ 
  rad(360), 0.5, 0, 0.5, 'stop_search', 'prune_branch', \ 
  'none', 0.8, 'least_squares', 0, 0.8, ModelStart, \ 
  ModelEnd, Score, RowComp, ColumnComp, AngleComp, \ 
  ScoreComp, ModelComp)
  ```

- Visualize the found instances.
  
  ```
  for i := 0 to |ModelStart|-1 by 1
  ```

get_found_component_model (FoundComponents, ComponentModelID, ModelStart, ModelEnd, RowComp, ColumnComp, AngleComp, ScoreComp, ModelComp, i, 'false', RowCompInst, ColumnCompInst, AngleCompInst, ScoreCompInst)

dev_display (FoundComponents)
endfor

train_model_components, create_component_model

________ Module ________

Matching

get_training_components ( :
   : TrainingComponents : ComponentTrainingID, Components, Image,
   : MarkOrientation : Row, Column, Angle, Score )

Return the initial or model components in a certain image.

get_training_components returns all initial components (if Components = 'initial_components') or all model components (if Components = 'model_components') in TrainingComponents in form of contour regions as well as in numerical form. Alternatively, by directly passing the index of an initial component, all found poses of that initial component (i.e., the poses before solving the ambiguities in train_model_components) are returned.

The pose of the returned components corresponds to their pose in the model image (if Image = 'model_image' or Image = 0) or in a training image (if Image ≥ 1). In order to obtain the components in the pose at which they were found in the ith training image, Image must be set to i. Furthermore, when dealing with rotationally symmetric components, one may wish to mark the current orientation of the found component. This can be achieved by setting MarkOrientation to 'true'. In this case, the contour region of each component is complemented by an arrow at its reference point pointing in the reference direction. The reference direction of a component is based on the orientation of the component in the model image and is represented by an arrow that starts at the reference point and points to the right in the horizontal direction.

In addition to the contour regions, the pose and the score of all found components is returned in Row, Column, Angle, and Score (see find_shape_model). If Components was set to 'initial_components' or 'model_components', the tuples TrainingComponents, Row, Column, Angle, and Score always contain the same number of elements as initial components or model components contained in ComponentTrainingID, respectively. If one component was not found in the image, an empty region is returned in the corresponding element of TrainingComponents and the elements of the four output control parameters are set to the value 0. In contrast, if the index of an initial component is passed in Components, these tuples contain as many elements as matches of the corresponding initial component were found in the image.

The operator get_training_components is particularly useful in order to visualize the result of the training ComponentTrainingID, which was performed with train_model_components. With this, it is possible to evaluate the suitability of the training images or to inspect the influence of the parameters of train_model_components. Sometimes it might be reasonable to restart the training with train_model_components using a different set of training images or after adjusting the parameters.
**Parameters**

- **TrainingComponents** (output_object) 
  Contour regions of the initial components or of the model components.  
- **ComponentTrainingID** (input_control) 
  Handle of the training result.  
- **Components** (input_control) 
  Type of returned components or index of an initial component.  
  **Default value:** 'model_components'  
  **Suggested values:** Components ∈ {'model_components', 'initial_components', 0, 1, 2, 3, 4, 5}
- **Image** (input_control) 
  Image for which the components are to be returned.  
  **Default value:** 'model_image'  
  **Suggested values:** Image ∈ {'model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8}
- **MarkOrientation** (input_control) 
  Mark the orientation of the components.  
  **Default value:** 'false'  
  **List of values:** MarkOrientation ∈ {'true', 'false'}
- **Row** (output_control) 
  Row coordinate of the found instances of all initial components or model components.  
- **Column** (output_control) 
  Column coordinate of the found instances of all initial components or model components.  
- **Angle** (output_control) 
  Rotation angle of the found instances of all components.  
- **Score** (output_control) 
  Score of the found instances of all components.

**Example**

```plaintext
* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (InitialComponentRegions, 298, 363, 1.17, 162, 34)
gen_rectangle2 (InitialComponentRegions, 63, 444, -0.26, 50, 27)
gen_rectangle2 (InitialComponentRegions, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images.
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
  read_image (TrainingImage, 'training_image-'+i+'.tif')
  concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, 
  TrainingImages, ModelComponents, 22, 60, 30, 0.6, 
  0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, 
  ComponentTrainingID)
* Visualize the result of the training.
count_obj (InitialComponentRegions, NumInitComp)
count_obj (TrainingImages, NumTrainings)
for i := 1 to NumTrainings by 1
  select_obj (TrainingImages, TrainingImage, i)
  for j := 0 to NumInitComp-1 by 1
    * Visualize the ambiguous poses of each initial component.
    get_training_components (TrainingComponents, ComponentTrainingID, 
      j, i, 'false', Row, Column, Angle, Score)
```

endfor
* Visualize the final poses of the initial components.
get_training_components (TrainingComponents, ComponentTrainingID, "initial_components", i, 'false', Row, Column, Angle, Score)
* Visualize the final poses of the model components.
get_training_components (TrainingComponents, ComponentTrainingID, "model_components", i, 'false', Row, Column, Angle, Score)
endfor

Result
If the handle of the training result is valid, the operator get_training_components returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Module

inspect_clustered_components ( :
: ModelComponents : ComponentTrainingID, AmbiguityCriterion,
MaxContourOverlap, ClusterThreshold :
)

Inspect the rigid model components obtained from the training.

inspect_clustered_components creates a representation of the rigid model components based on the training result ComponentTrainingID in form of contour regions. The resulting rigid model components are computed depending on the criterion that is used to solve the ambiguities AmbiguityCriterion, the maximum allowable contour overlap MaxContourOverlap, and the cluster threshold ClusterThreshold (see train_model_components). The cluster threshold, for example, influences the merging of the initial components. The greater the threshold is chosen, the fewer initial components are merged. The determined rigid model components are returned in ModelComponents.

Hence, after the components have been trained once by using train_model_components, inspect_clustered_components can be used to estimate the effect of different values for the parameters AmbiguityCriterion, MaxContourOverlap, and ClusterThreshold without performing the complete training procedure several times. Once the desired parameter values have been found, they can be efficiently adopted into the training result by using cluster_model_components.

Parameters

- **ModelComponents** (output_object) : region(-array) ~ object
  Contour regions of rigid model components.
- **ComponentTrainingID** (input_control) : component_training ~ handle
  Handle of the training result.
- **AmbiguityCriterion** (input_control) : string ~ string
  Criterion for solving the ambiguities.

  Default value: 'rigidity'

  List of values: AmbiguityCriterion ∈ {'distance', 'orientation', 'distance_orientation', 'rigidity'}
MaxContourOverlap (input_control)  
Maximum contour overlap of the found initial components.

Default value: 0.2
Suggested values: MaxContourOverlap ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 ≤ MaxContourOverlap && MaxContourOverlap ≤ 1

ClusterThreshold (input_control)  
Threshold for clustering the initial components.

Default value: 0.5
Suggested values: ClusterThreshold ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: 0 ≤ ClusterThreshold && ClusterThreshold ≤ 1

Example

* Get the model image.
read_image (ModelImage, 'model_image.tif')

* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)

* Get the training images
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i$'02'+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor

* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, TrainingImages, ModelComponents, 22, 60, 30, 0.65, ComponentTrainingID)

* Find the best value for the parameter ClusterThreshold.
inspect_clustered_components (ModelComponents, ComponentTrainingID, 'rigidity', 0.2, 0.4)

* Adopt the ClusterThreshold into the training result.
cluster_model_components (ModelComponents, ModelComponents, ComponentTrainingID, 'rigidity', 0.2, 0.4)

* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, 0.5, 'auto', 'auto', 'none', 'use_polarity', 'false', ComponentModelID, RootRanking)

Result
If the handle of the training result is valid, the operator inspect_clustered_components returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.
modify_component_relations ( : : ComponentTrainingID, ReferenceComponent, ToleranceComponent, PositionTolerance, AngleTolerance : )

Modify the relations within a training result.

modify_component_relations modifies the relations between the model components within the component training result ComponentTrainingID. The selection of the relation(s) that should be changed is performed by setting ReferenceComponent and ToleranceComponent, respectively. This means that the relative movement of component ToleranceComponent with respect to the component ReferenceComponent is modified.

The size of the change is specified as follows: By specifying a position tolerance PositionTolerance, the semi-axes of the rectangle that describes the reference point’s movement (see train_model_components) are enlarged by PositionTolerance pixels. Accordingly, by specifying an orientation tolerance AngleTolerance, the angle range that describes the variation of the relative orientation (see train_model_components) is enlarged by AngleTolerance to both sides. Consequently, negative tolerance values lead to a decreased size of the relations. The operator modify_component_relations is particularly useful when the training images that were used during the training do not cover the entire spectrum of the relative movements.

In order to select the relations that should be modified, values for ReferenceComponent and ToleranceComponent can be passed in one of the following ways: For each of both parameters either one value, several values, or the string 'all' can be passed. The following table summarizes the different possibilities by giving the affected relations for different combinations of parameter values. Here, four model components are assumed (0, 1, 2, and 3). If, for example, ReferenceComponent is set to 0 and ToleranceComponent is set to 1, then the relation (0,1), which corresponds to the relative movement of component 1 with respect to component 0, will be modified.
The number of tolerance values passed in `PositionTolerance` and `AngleTolerance` must be either 1 or be equal to the number of affected relations. In the former case all affected relations are modified by the same value, whereas in the latter case each relation can be modified individually by passing different values within a tuple.

### Parameters

- `ComponentTrainingID` (input_control) `component_training` → `handle` Handle of the training result.
- `ReferenceComponent` (input_control) `string(-array)` → `string / integer` Model component(s) relative to which the movement(s) should be modified.  
  **Default value:** 'all'  
  **Suggested values:** `ReferenceComponent ∈ ['all', 0, 1, 2, 3, 4, 5, 6]`
- `ToleranceComponent` (input_control) `string(-array)` → `string / integer` Model component(s) of which the relative movement(s) should be modified.  
  **Default value:** 'all'  
  **Suggested values:** `ToleranceComponent ∈ ['all', 0, 1, 2, 3, 4, 5, 6]`
- `PositionTolerance` (input_control) `real(-array)` → `real` Change of the position relation in pixels.  
  **Suggested values:** `PositionTolerance ∈ [1.0, 2.0, 3.0, 4.0, 5.0, 10.0, 20.0, 30.0]`
- `AngleTolerance` (input_control) `angle.rad(-array)` → `real` Change of the orientation relation in radians.  
  **Suggested values:** `AngleTolerance ∈ [0.017, 0.035, 0.052, 0.070, 0.087, 0.175, 0.349]`

### Result

If the handle of the training result is valid, the operator `modify_component_relations` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
This operator modifies the state of the following input parameter:

- ComponentTrainingID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

```
train_model_components
```

### Possible Predecessors

```
create_trained_component_model
```

### Possible Successors

```
Module
```

**Matching**

```
read_component_model ( : : FileName : ComponentModelID )
```

**Read a component model from a file.**

The operator `read_component_model` reads a component model, which has been written with `write_component_model`, from the file `FileName` and returns it in `ComponentModelID`. The default HALCON file extension for the component model is `cbm`.

```
Parameters

- FileName (input_control) ........................................ filename.read ~ string
  File name.
  File extension: .cbm

- ComponentModelID (output_control) ..................... component_model ~ handle
  Handle of the component model.
```

**Result**

If the file name is valid, the operator `read_component_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```
find_component_model
```

**Possible Successors**

```
Module
```

**Matching**

```
read_training_components ( : : FileName : ComponentTrainingID )
```

**Read a component training result from a file.**

The operator `read_training_components` reads a component training result, which has been written with `write_training_components`, from the file `FileName` and returns it in `ComponentTrainingID`. The default HALCON file extension for the component training result is `ct`.

HALCON 20.05.0.0
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileName (input_control)</td>
<td>File name. File extension: .ct</td>
</tr>
<tr>
<td>ComponentTrainingID (output_control)</td>
<td>Handle of the training result.</td>
</tr>
</tbody>
</table>

If the file name is valid, the operator `read_training_components` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Successors

- `create_trained_component_model`
- `train_model_components, clear_training_components`

### Module

```
serialize_component_model (  
    : : ComponentModelID : SerializedItemHandle )
```

**Serialize a component model.**

`serialize_component_model` serializes the data of a component model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_component_model` is converted to a serialized item. The component model is defined by the handle `ComponentModelID`. The serialized component model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_component_model`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ComponentModelID (input_control)</td>
<td>Handle of the component model.</td>
</tr>
<tr>
<td>SerializedItemHandle (output_control)</td>
<td>Handle of the serialized item.</td>
</tr>
</tbody>
</table>

If the parameters are valid, the operator `serialize_component_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `create_component_model, create_trained_component_model`

### Possible Successors

- `fwrite_serialized_item, send_serialized_item, deserialize_component_model`

### Module

```
```
serialize_training_components ( ComponentTrainingID : SerializedItemHandle )

Serialize a component training result.

serialize_training_components serializes the data of a component training result (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_training_components is converted to a serialized item. The component training result is defined by the handle ComponentTrainingID. The serialized component training result is returned by the handleSerializedItemHandle and can be deserialized by deserialize_training_components.

Parameters

- ComponentTrainingID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . component_training ~ handle Handle of the training result.
- SerializedItemHandle (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . serialized_item ~ handle Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_training_components returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

train_model_components

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_training_components

Module

Train components and relations for the component-based matching.

train_model_components extracts the final (rigid) model components and trains their mutual relations, i.e., their relative movements, on the basis of the initial components by considering several training images. The result of the training is returned in the handle ComponentTrainingID. The training result can be subsequently used to create the actual component model using create_trained_component_model.

train_model_components should be used in cases where the relations of the components are not known and should be trained automatically. In contrast, if the relations are known no training needs to be performed with train_model_components. Instead, the component model can be directly created with create_component_model.

If the initial components have been automatically created by using gen_initial_components, InitialComponents contains the contour regions of the initial components. In contrast, if the initial components should be defined by the user, they can be directly passed in InitialComponents. However, instead of the contour regions for each initial component, its enclosing region must be passed in the tuple. The (contour) regions refer to the model image ModelImage. If the initial components have been obtained using gen_initial_components, the model image should be the same as in gen_initial_components. Please note that each initial component is part of at most one rigid model component. This is because during the
training initial components can be merged into rigid model components if required (see below). However, they cannot be split and distributed to several rigid model components.

\texttt{train\_model\_components} uses the following approach to perform the training: In the first step, the initial components are searched in all training images. In some cases, one initial component may be found in an training image more than once. Thus, in the second step, the resulting ambiguities are solved, i.e., the most probable pose of each initial component is found. Consequently, after solving the ambiguities, in all training images at most one pose of each initial component is available. In the next step the poses are analyzed and those initial components that do not show any relative movement are clustered to the final rigid model components. Finally, in the last step the relations between the model components are computed by analyzing their relative poses over the sequence of training images. The parameters that are associated with the mentioned steps are explained in the following.

The training is performed based on several training images, which are passed in \texttt{TrainingImages}. Each training image must show at most one instance of the compound object and should contain the full range of allowed relative movements of the model components. If, for example, the component model of an on/off switch should be trained, one training image that shows the switch turned off is sufficient if the switch in the model image is turned on, or vice versa.

The principle of the training is to find the initial components in all training images and to analyze their poses. For this, for each initial component a shape model is created (see \texttt{create\_shape\_model}), which is then used to determine the poses (position and orientation) of the initial components in the training images (see \texttt{find\_shape\_model}). Depending on the mode that is set by using \texttt{set\_system} (\texttt{’pregenerate\_shape\_models’},...), the shape model is either pregenerated completely or computed online during the search. The mode influences the computation time as well as the robustness of the training. Furthermore, it should be noted that if single-channel image are used in \texttt{ModelImage} as well as in \texttt{TrainingImages} the metric \texttt{’use\_polarity’} is used internally for \texttt{create\_shape\_model}, while if multichannel images are used in either \texttt{ModelImage} or \texttt{TrainingImages} the metric \texttt{’ignore\_color\_polarity’} is used. Finally, it should be noted that while the number of channels in \texttt{ModelImage} and \texttt{TrainingImages} may be different, e.g., to facilitate model generation from synthetically generated images, the number of channels in all the images in \texttt{TrainingImages} must be identical. For further details see \texttt{create\_shape\_model}. The creation of the shape models can be influenced by choosing appropriate values for the parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize}. These parameters have the same meaning as in \texttt{gen\_initial\_components} and can be automatically determined by passing \texttt{’auto’}. If both hysteresis threshold should be automatically determined, both \texttt{ContrastLow} and \texttt{ContrastHigh} must be set to \texttt{’auto’}. In contrast, if only one threshold value should be determined, \texttt{ContrastLow} must be set to \texttt{’auto’} while \texttt{ContrastHigh} must be set to an arbitrary value different from \texttt{’auto’}. If the initial components have been automatically created by \texttt{gen\_initial\_components}, the parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize} should be set to the same values as in \texttt{gen\_initial\_components}.

To influence the search for the initial components, the parameters \texttt{MinScore}, \texttt{SearchRowTol}, \texttt{SearchColumnTol}, \texttt{SearchAngleTol}, and \texttt{TrainingEmphasis} can be set. The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the initial component in the training image. The larger \texttt{MinScore} is chosen, the faster the training is. If the initial components can be expected never to be occluded in the training images, \texttt{MinScore} may be set as high as 0.8 or even 0.9 (see \texttt{find\_shape\_model}).

By default, the components are searched only at points in which the component lies completely within the respective training image. This means that a component will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than \texttt{MinScore}. This behavior can be changed with \texttt{set\_system} (\texttt{’border\_shape\_models’},\texttt{’true’}), which will cause components that extend beyond the image border to be found if they achieve a score greater than \texttt{MinScore}. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the training will increase in this mode.

When dealing with a high number of initial components and many training images, the training may take a long time (up to several minutes). In order to speed up the training it is possible to restrict the search space for the single initial components in the training images. For this, the poses of the initial components in the model image are used as reference pose. The parameters \texttt{SearchRowTol} and \texttt{SearchColumnTol} specify the position tolerance region relative to the reference position in which the search is performed. Assume, for example, that the position of an initial component in the model image is (100,200) and \texttt{SearchRowTol} is set to 20 and \texttt{SearchColumnTol} is set to 10. Then, this initial component is searched in the training images only within the axis-aligned rectangle that is determined by the upper left corner (80,190) and the lower right corner (120,210). The same holds for the orientation angle range, which can be restricted by specifying the angle tolerance \texttt{SearchAngleTol} to
the angle range of \([-\text{SearchAngleTol}, +\text{SearchAngleTol}]\). Thus, it is possible to considerably reduce the computational effort during the training by an adequate acquisition of the training images. If one of the three parameters is set to \(-1\), no restriction of the search space is applied in the corresponding dimension.

The input parameters \text{ContrastLow}, \text{ContrastHigh}, \text{MinSize}, \text{MinScore}, \text{SearchColumnTol}, \text{SearchRowTol}, \text{SearchColumnTol}, \text{and SearchAngleTol} must either contain one element, in which case the parameter is used for all initial components, or must contain the same number of elements as the initial components contained in \text{InitialComponents}, in which case each parameter element refers to the corresponding initial component in \text{InitialComponents}.

The parameter \text{TrainingEmphasis offers another possibility to influence the computation time of the training and to simultaneously affect its robustness. If \text{TrainingEmphasis is set to \textquote{speed}, on the one hand the training is comparatively fast, on the other hand it may happen in some cases that some initial components are not found in the training images or are found at a wrong pose. Consequently, this would lead to an incorrect computation of the rigid model components and their relations. The poses of the found initial components in the individual training images can be examined by using \text{get_training_components}. If erroneous matches occur the training should be restarted with \text{TrainingEmphasis set to \textquote{reliability}. This results in a higher robustness at the cost of a longer computation time.

Furthermore, during the pose determination of the initial components ambiguities may occur if the initial components are rotationally symmetric or if several initial components are identical or at least similar to each other. To solve the ambiguities, the most probable pose is calculated for each initial component in each training image. For this, the individual ambiguous poses are evaluated. The pose of an initial component receives a good evaluation if the relative pose of the initial component with respect to the other initial components is similar to the corresponding relative pose in the model image. The method to evaluate this similarity can be chosen with \text{AmbiguityCriterion}. In almost all cases the best results are obtained with \textquote{rigidity}, which assumes the rigidity of the compound object. The more the rigidity of the compound object is violated by the pose of the initial component, the worse its evaluation is. In the case of \textquote{distance}, only the distance between the initial components is considered during the evaluation. Hence, the pose of the initial component receives a good evaluation if its distances to the other initial components is similar to the corresponding distances in the model image. Accordingly, when choosing \textquote{orientation}, only the relative orientation is considered during the evaluation. Finally, the simultaneous consideration of distance and orientation can be achieved by choosing \textquote{distance_orientation}. In contrast to \textquote{rigidity}, the relative pose of the initial components is not considered when using \textquote{distance_orientation}.

The process of solving the ambiguities can be further influenced by the parameter \text{MaxContourOverlap}. This parameter describes the extent by which the contours of two initial component matches may overlap each other. Let the letters ‘I’ and ‘T’, for example, be two initial components that should be searched in a training image that shows the string ‘IT’. Then, the initial component ‘T’ should be found at its correct pose. In contrast, the initial component ‘I’ will be found at its correct pose (‘I’) but also at the pose of the ‘T’ because of the similarity of the two components. To discard the wrong match of the initial component ‘T’, an appropriate value for \text{MaxContourOverlap} can be chosen: If overlapping matches should be tolerated, \text{MaxContourOverlap should be set to 1}. If overlapping matches should be completely avoided, \text{MaxContourOverlap should be set to 0}. By choosing a value between 0 and 1, the maximum percentage of overlapping contour pixels can be adjusted.

The decision which initial components can be clustered to rigid model components is made based on the poses of the initial components in the model image and in the training images. Two initial components are merged if they do not show any relative movement over all images. Assume that in the case of the above mentioned switch the training image would show the same switch state as the model image, the algorithm would merge the respective initial components because it assumes that the entire switch is one rigid model component. The extent by which initial components are merged can be influenced with the parameter \text{ClusterThreshold}. This cluster threshold is based on the probability that two initial components belong to the same rigid model component. Thus, \text{ClusterThreshold describes the minimum probability which two initial components must have in order to be merged. Since the threshold is based on a probability value, it must lie in the interval between 0 and 1}. The greater the threshold is chosen, the smaller the number of initial components that are merged. If a threshold of 0 is chosen, all initial components are merged into one rigid component, while for a threshold of 1 no merging is performed and each initial component is adopted as one rigid model component.

The final rigid model components are returned in \text{ModelComponents}. Later, the index of a component region in \text{ModelComponents} is used to denote the model component. The poses of the components in the training images can be examined by using \text{get_training_components}.

After the determination of the model components their relative movements are analyzed by determining the movement of one component with respect to a second component for each pair of components. For this, the components are referred to their reference points. The reference point of a component is the center of gravity of its contour.
region, which is returned in ModelComponents. It can be calculated by calling area_center. Finally, the relative movement is represented by the smallest enclosing rectangle of arbitrary orientation of the reference point movement and by the smallest enclosing angle interval of the relative orientation of the second component over all images. The determined relations can be inspected by using get_component_relations.

### Parameters

- **ModelImage** (input_object) (multichannel-)image \(\leadsto object : \text{byte} / \text{uint2}

  Input image from which the shape models of the initial components should be created.

- **InitialComponents** (input_object) region-array \(\leadsto object

  Contour regions or enclosing regions of the initial components.

- **TrainingImages** (input_object) (multichannel-)image(-array) \(\leadsto object : \text{byte} / \text{uint2}

  Training images that are used for training the model components.

- **ModelComponents** (output_object) region(-array) \(\leadsto object

  Contour regions of rigid model components.

- **ContrastLow** (input_control) integer(-array) \(\leadsto integer / \text{string}

  Lower hysteresis threshold for the contrast of the initial components in the image.

  Default value: ‘auto’

  Suggested values: ContrastLow ∈ \{'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\}

  Restriction: ContrastLow > 0

- **ContrastHigh** (input_control) integer(-array) \(\leadsto integer / \text{string}

  Upper hysteresis threshold for the contrast of the initial components in the image.

  Default value: ‘auto’

  Suggested values: ContrastHigh ∈ \{'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\}

  Restriction: ContrastHigh > 0 && ContrastHigh >= ContrastLow

- **MinSize** (input_control) integer(-array) \(\leadsto integer / \text{string}

  Minimum size of connected contour regions.

  Default value: ‘auto’

  Suggested values: MinSize ∈ \{'auto', 0, 5, 10, 20, 30, 40\}

  Restriction: MinSize >= 0

- **MinScore** (input_control) real(-array) \(\leadsto real

  Minimum score of the instances of the initial components to be found.

  Default value: 0.5

  Suggested values: MinScore ∈ \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}

  Minimum increment: 0.01

  Recommended increment: 0.05

  Restriction: 0 <= MinScore && MinScore <= 1

- **SearchRowTol** (input_control) integer(-array) \(\leadsto integer

  Search tolerance in row direction.

  Default value: -1

  Suggested values: SearchRowTol ∈ \{0, 10, 20, 30, 50, 100\}

  Restriction: SearchRowTol == -1 || SearchRowTol >= 0

- **SearchColumnTol** (input_control) integer(-array) \(\leadsto integer

  Search tolerance in column direction.

  Default value: -1

  Suggested values: SearchColumnTol ∈ \{0, 10, 20, 30, 50, 100\}

  Restriction: SearchColumnTol == -1 || SearchColumnTol >= 0

- **SearchAngleTol** (input_control) angle.rad(-array) \(\leadsto real

  Angle search tolerance.

  Default value: -1

  Suggested values: SearchAngleTol ∈ \{0.0, 0.17, 0.39, 0.78, 1.57\}

  Restriction: SearchAngleTol == -1 || SearchAngleTol >= 0

- **TrainingEmphasis** (input_control) string \(\leadsto string

  Decision whether the training emphasis should lie on a fast computation or on a high robustness.

  Default value: ‘speed’

  List of values: TrainingEmphasis ∈ \{'speed', 'reliability'\}
18.1. COMPONENT-BASED

- **AmbiguityCriterion** (input_control) ................................. string ~ string
 Criterion for solving ambiguous matches of the initial components in the training images.
  Default value: ‘rigidity’
  List of values: AmbiguityCriterion ∈ {’distance’, ’orientation’, ’distance_orientation’, ’rigidity’}

- **MaxContourOverlap** (input_control) ................................. real ~ real
  Maximum contour overlap of the found initial components in a training image.
  Default value: 0.2
  Suggested values: MaxContourOverlap ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: 0 <= MaxContourOverlap && MaxContourOverlap <= 1

- **ClusterThreshold** (input_control) ................................. real ~ real
  Threshold for clustering the initial components.
  Default value: 0.5
  Suggested values: ClusterThreshold ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: 0 <= ClusterThreshold && ClusterThreshold <= 1

- **ComponentTrainingID** (output_control) ............................ component_training ~ handle
  Handle of the training result.

--- Example ---

* Get the model image.
  read_image (ModelImage, ’model_image.tif’)
* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
  gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
  gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
  gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
  concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images.
  gen_empty_obj (TrainingImages)
  for i := 1 to 4 by 1
    read_image (TrainingImage, ’training_image-’+i+’’.tif’)
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
  endfor
* Extract the model components and train the relations.
  train_model_components (ModelImage, InitialComponentRegions, \ TrainingImages, ModelComponents, 22, 60, 30, 0.6, \ 0, 0, rad(60), ’speed’, ’rigidity’, 0.2, 0.4, \ ComponentTrainingID)

--- Result ---

If the parameter values are correct, the operator train_model_components returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system (’no_object_result,’<Result>). If necessary, an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

write_component_model ( : : ComponentModelID, FileName : )

Write a component model to a file.
The operator write_component_model writes the component model ComponentModelID to the file FileName. The model can be read again with read_component_model. The default HALCON file extension for the component model is 'cbm'.

Parameters

ComponentModelID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . component_model ~ handle
Handle of the component model.

FileName (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . filename.write ~ string
File name.

File extension: .cbm

Result

If the file name is valid (write permission), the operator write_component_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

18.2 Correlation-Based

clear_ncc_model ( : : ModelID : )

Free the memory of an NCC model.
The operator clear_ncc_model frees the memory of an NCC model that was created by create_ncc_model. After calling clear_ncc_model, the model can no longer be used. The handle ModelID becomes invalid.

Parameters

> ModelID (input_control) ........................................ ncc_model ~ handle
Handle of the model.

Result
If the handle of the model is valid, the operator clear_ncc_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_ncc_model, read_ncc_model, write_ncc_model, find_ncc_model, find_ncc_models

Module

create_ncc_model ( Template : : NumLevels, AngleStart, AngleExtent, AngleStep, Metric : ModelID )

Prepare an NCC model for matching.
The operator `create_ncc_model` prepares a template, which is passed in the image `Template`, as an NCC model used for matching using the normalized cross correlation (NCC). The ROI of the model is passed as the domain of `Template`.

The model is generated using multiple image pyramid levels at multiple rotations on each level and is stored in memory. The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_ncc_model`.

The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least eight) on the highest pyramid level. This can be checked using the domains of the output images of `gen_gauss_pyramid`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_ncc_model` returns an error message. If `NumLevels` is set to `'auto'` or 0, `create_ncc_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_ncc_model_params`. In rare cases, it might happen that `create_ncc_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` in `find_ncc_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_ncc_model` may increase. In these cases, the number of pyramid levels should be selected by inspecting the output of `gen_gauss_pyramid`. Here, `Mode = 'constant'` and `Scale = 0.5` should be used.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_ncc_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_ncc_model`, this parameter specifies the accuracy that is achievable for the angles in `find_ncc_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure a sampling of the range of possible rotations that is independent of the given `AngleStart`, the range of possible rotations is modified as follows: If there is no positive integer value `n` such that `AngleStart` plus `n` times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

The model is pre-generated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if `AngleStep` is too small or `AngleExtent` too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either `AngleStep` must be enlarged or `AngleExtent` must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_ncc_model`, `AngleStep > 1` can be selected for models of a diameter smaller than about 200 pixels. If `AngleStep = 'auto'` or 0 is selected, `create_ncc_model` automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using `get_ncc_model_params`.

The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_ncc_model` will increase slightly in this case.

The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin can be set with `set_ncc_model_origin`.

**Parameters**

- **Template** (input_object) .......................... singlechannelimage ˜ object : byte / uint2
  Input image whose domain will be used to create the model.
18.2. CORRELATION-BASED

- **NumLevels** (input_control) ............................................. integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: NumLevels ∈ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) .............................................. angle.rad → real
  Smallest rotation of the pattern.
  Default value: -0.39
  Suggested values: AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.2, 0.0}

- **AngleExtent** (input_control) ............................................. angle.rad → real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}
  Restriction: AngleExtent >= 0

- **AngleStep** (input_control) ............................................. angle.rad → real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: AngleStep ∈ {'auto', 0.0, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
  Restriction: AngleStep >= 0 && AngleStep <= pi / 16

- **Metric** (input_control) ............................................... string → string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric ∈ {'use_polarity', 'ignore_global_polarity'}

- **ModelID** (output_control) ............................................. ncc_model → handle
  Handle of the model.

If the parameters are valid, the operator `create_ncc_model` returns the value 2 (H_MSG_TRUE). If the parameter `NumLevels` are chosen such that the model contains too few points, the error 8506 is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors: `draw_region, reduce_domain, threshold`
Possible Successors: `find_ncc_model, get_ncc_model_params, clear_ncc_model, write_ncc_model, set_ncc_model_origin, set_ncc_model_param, find_ncc_models`
Alternatives: `create_shape_model, create_scaled_shape_model, create_aniso_shape_model`
Module: `Matching`

```plaintext
deserialize_ncc_model ( : : SerializedItemHandle : ModelID )
```

Deserializes an NCC model.

deserialize_ncc_model deserializes an NCC model, that was serialized by `serialize_ncc_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized NCC model model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created NCC model with the handle `ModelID`.

HALCON 20.05.0.0
CHAPTER 18 MATCHING

--- Parameters ---

- **SerializedItemHandle** (input_control) ........................................... serialized_item ↳ handle
  Handle of the serialized item.
- **ModelID** (output_control) ............................................................ ncc_model ↳ handle
  Handle of the model.

--- Result ---

If the parameters are valid, the operator `deserialize_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Matching

```

determine_ncc_model_params ( Template : : NumLevels, AngleStart, AngleExtent, Metric, Parameters : ParameterName, ParameterValue )
```

**Determine the parameters of an NCC model.**

determine_ncc_model_params determines certain parameters of an NCC model automatically from the model image `Template`. The parameters to be determined can be specified with `Parameters`. determine_ncc_model_params can be used to determine the same parameters that are determined automatically when the respective parameter in `create_ncc_model` is set to ‘auto’: the number of pyramid levels (`Parameters = 'num_levels'`) and/or the angle step length (`Parameters = 'angle_step'`). By passing a tuple of the above values in `Parameters`, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value ‘all’ can be passed.

determine_ncc_model_params is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in `ParameterName` and `ParameterValue`. The parameter names in `ParameterName` are identical to the names in `Parameters`, where, of course, the value ‘all’ is replaced by the actual parameter names.

The input parameters (`NumLevels`, `AngleStart`, `AngleExtent`, and `Metric`) have the same meaning as in `create_ncc_model`. The description of these parameters can be looked up with this operator. These parameters are used by `determine_ncc_model_params` to calculate the parameters to be determined in the same manner as in `create_ncc_model`.

Note that in `determine_ncc_model_params` the input parameter `NumLevels` can also be determined automatically. If this parameter should not be determined automatically, i.e., the name is not passed in `Parameters`, the parameter must contain a valid value and must not be set to ‘auto’. In contrast, if the maximum number of pyramid levels is to be determined automatically, i.e., `Parameters` contains the value ‘num_levels’, you can let HALCON determine a suitable value and at the same time specify an upper boundary:

If the maximum number of pyramid levels should be specified in advance, the input parameter `NumLevels` can be set to the particular value. If in this case `Parameters` contains the value ‘num_levels’, the computed number of pyramid levels is at most `NumLevels`. If `NumLevels` is set to ‘auto’ or 0, the number of pyramid levels is determined without restrictions as large as possible.
18.2. CORRELATION-BASED

**Parameters**

- **Template** (input_object) ............................................ singlechannelimage \(\sim\) object : byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) ............................................ integer \(\sim\) integer / string
  Maximum number of pyramid levels.
  **Default value:** ‘auto’
  **List of values:** NumLevels \(\in\) {‘auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) ............................................ angle.rad \(\sim\) real
  Smallest rotation of the model.
  **Default value:** -0.39
  **Suggested values:** AngleStart \(\in\) {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

- **AngleExtent** (input_control) ............................................ angle.rad \(\sim\) real
  Extent of the rotation angles.
  **Default value:** 0.79
  **Suggested values:** AngleExtent \(\in\) {6.29, 3.14, 1.57, 0.79, 0.39}
  **Restriction:** AngleExtent \(\geq\) 0

- **Metric** (input_control) ............................................ string \(\sim\) string
  Match metric.
  **Default value:** ‘use_polarity’
  **List of values:** Metric \(\in\) {‘use_polarity’, ‘ignore_global_polarity’}

- **Parameters** (input_control) ............................................ string(-array) \(\sim\) string
  Parameters to be determined automatically.
  **Default value:** ‘all’
  **List of values:** Parameters \(\in\) {‘all’, ‘num_levels’, ‘angle_step’}

- **ParameterName** (output_control) .................................... string-array \(\sim\) string
  Name of the automatically determined parameter.

- **ParameterValue** (output_control) .................................... number-array \(\sim\) real / integer
  Value of the automatically determined parameter.

**Result**

If the parameters are valid, the operator `determine_ncc_model_params` returns the value 2 (H_MSG_TRUE).

**Parallelization**

**Module**

Matching

```plaintext
find_ncc_model ( Image : : ModelID, AngleStart, AngleExtent, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels : Row, Column, Angle, Score )
```

Find the best matches of an NCC model in an image.

The operator `find_ncc_model` finds the best `NumMatches` instances of the NCC model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_ncc_model` or `read_ncc_model`.

The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. Additionally, the score of each found instance is returned in `Score`.

HALCON 20.05.0.0
It should be noted that the NCC is very sensitive to occlusion and clutter as well as to nonlinear illumination changes in the image. If a model should be found in the presence of occlusion, clutter, or nonlinear illumination changes the search should be performed using the shape-based matching (see, e.g., `create_shape_model`).

**Input parameters in detail**

**The image and its domain:** The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin set with `set_ncc_model_origin` is not taken into account here. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that rounding effects can cause matches to lie up to \(0.5 \times 2^{\text{NumLevels}-1}\) pixels outside the image.

**AngleStart and AngleExtent:** The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with `create_ncc_model`.

**MinScore:** The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is.

**NumMatches:** The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

**MaxOverlap:** If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. If the model has repeating structures it may happen that multiple instances with identical rotations are found at similar positions in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap = 0`, the found instances may not overlap at all, while for `MaxOverlap = 1` all instances are returned.

**SubPixel:** The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to `'false'`, the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`. If `SubPixel` is set to `'true'`, the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves a high accuracy. Hence, `SubPixel` should usually be set to `'true'`. Note that the subpixel accurate determination of the model’s pose is only possible if the found instance lies at least 2 pixels away from the image border of the lowest used pyramid level. If the instance lies closer to the image border, its pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`, even if `SubPixel` is set to `'true'`.

**NumLevels:** The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the NCC model was created with `create_ncc_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_ncc_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_ncc_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_ncc_model_params` and then use a slightly lower value in `find_ncc_model`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances.
of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

**Output parameters in detail**

**Row, Column and Angle:** The position and rotation of the found instances of the model is returned in **Row**, **Column**, and **Angle**. The coordinates **Row** and **Column** are related to the position of the origin of the model in the search image. However, **Row** and **Column** do not exactly correspond to this position. Instead, **find_ncc_model** returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model. (This has to do with the way HALCON transforms iconic objects, see **affine_trans_pixel**). The example below shows how to create the transformation matrix for alignment and how to calculate the exact coordinates of the found matches.

By default, the origin is the center of gravity of the domain (region) of the image that was used to create the NCC model with **create_ncc_model**. A different origin can be set with **set_ncc_model_origin**.

**Score:** Additionally, the score of each found instance is returned in **Score**. The score is the normalized cross correlation of the template \( t(r, c) \) and the image \( i(r, c) \):

\[
\text{ncc}(r, c) = \frac{1}{n} \sum_{(u,v) \in R} \frac{t(u,v) - m_t}{\sqrt{s^2_t}} \cdot \frac{i(r + u, c + v) - m_i(r, c)}{\sqrt{s^2_i(r, c)}}
\]

Here, \( n \) denotes the number of points in the template, \( R \) denotes the domain (ROI) of the template, \( m_t \) is the mean gray value of the template

\[
m_t = \frac{1}{n} \sum_{(u,v) \in R} t(u,v)
\]

\( s^2_t \) is the variance of the gray values of the template

\[
s^2_t = \frac{1}{n} \sum_{(u,v) \in R} (t(u,v) - m_t)^2
\]

\( m_i(r, c) \) is the mean gray value of the image at position \( (r, c) \) over all points of the template (i.e., the template points are shifted by \( (r, c) \))

\[
m_i(r, c) = \frac{1}{n} \sum_{(u,v) \in R} i(r + u, c + v)
\]

and \( s^2_i(r, c) \) is the variance of the gray values of the image at position \( (r, c) \) over all points of the template

\[
s^2_i(r, c) = \frac{1}{n} \sum_{(u,v) \in R} (i(r + u, c + v) - m_i(r, c))^2
\]

The NCC measures how well the template and image correspond at a particular point \( (r, c) \). It assumes values between \(-1\) and \(1\). The larger the absolute value of the correlation, the larger the degree of correspondence between the template and image. A value of \(1\) means that the gray values in the image are a linear transformation of the gray values in the template:

\[
i(r + u, c + v) = at(u,v) + b
\]

where \( a > 0 \). Similarly, a value of \(-1\) means that the gray values in the image are a linear transformation of the gray values in the template with \( a < 0 \). Hence, in this case the template occurs with a reversed polarity in the image. Because of the above property, the NCC is invariant to linear illumination changes.

The NCC as defined above is used if the NCC model has been created with **Metric** = ‘use_polarity’. If the model has been created with **Metric** = ‘ignore_global_polarity’, the absolute value of \( \text{ncc}(r, c) \) is used as the score.
CHAPTER 18 MATCHING

Specifying a timeout

Using the operator set_ncc_model_param you can specify a 'timeout' for find_ncc_model. If find_ncc_model reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by correlation-based matching, we highly recommend the usage of the procedure dev_display_ncc_matching_results.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

find_ncc_model can be partially executed on OpenCL devices that support the cl_khr_global_int32_base_atomics OpenCL extension. Only the initial search for the model in the topmost pyramid level is done on the OpenCL device, while the tracking of matches is done on the host CPU. If the domain of the image to search in is substantially smaller than the size of the image, use crop_domain to reduce the amount of data that needs to be copied from the OpenCL device to the host CPU. Note that find_ncc_model using OpenCL may run either substantially faster or slower depending on a wide number of factors, so the only way to tell if using OpenCL is beneficial is by testing with images from the actual application.

Furthermore, note that the internally used memory increases with the number of used threads.

Parameters

- **Image** (input_object) .......................... singlechannelimage ~ object : byte / uint2
  Input image in which the model should be found.
- **ModelID** (input_control) ......................... ncc_model ~ handle
  Handle of the model.
- **AngleStart** (input_control) ...................... angle.rad ~ real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- **AngleExtent** (input_control) .................... angle.rad ~ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39, 0.0}
  Restriction: AngleExtent ≥ 0
- **MinScore** (input_control) ........................ real ~ real
  Minimum score of the instances of the model to be found.
  Default value: 0.8
  Suggested values: MinScore ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: 0 ≤ MinScore ≤ 1
  Minimum increment: 0.01
  Recommended increment: 0.05
- **NumMatches** (input_control) ..................... integer ~ integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: NumMatches ∈ {0, 1, 2, 3, 4, 5, 10, 20}
- **MaxOverlap** (input_control) ..................... real ~ real
  Maximum overlap of the instances of the model to be found.
  Default value: 0.5
  Suggested values: MaxOverlap ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: 0 ≤ MaxOverlap ≤ 1
  Minimum increment: 0.01
  Recommended increment: 0.05
- **SubPixel** (input_control) ........................ string ~ string
  Subpixel accuracy.
  Default value: ‘true’
  List of values: SubPixel ∈ {'false', 'true'}
18.2. CORRELATION-BASED

- **NumLevels** (input_control) .................................................. integer(-array)  integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
  **Default value:** 0
  **List of values:** NumLevels ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **Row** (output_control) ......................................................... point.y-array  real
  Row coordinate of the found instances of the model.

- **Column** (output_control) ..................................................... point.x-array  real
  Column coordinate of the found instances of the model.

- **Angle** (output_control) ....................................................... angle.rad-array  real
  Rotation angle of the found instances of the model.

- **Score** (output_control) ....................................................... real-array  real
  Score of the found instances of the model.

**Example**

```
create_ncc_model (TemplateImage, 'auto', rad(-45), rad(90), 'auto', \    'use_polarity', ModelID)
fund_ncc_model (SearchImage, ModelID, rad(-45), rad(90), 0.7, 1, \    0.5, 'true', 0, Row, Column, Angle, Score)  
```

**Result**

If the parameter values are correct, the operator `find_ncc_model` returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via `set_system`
(‘no_object_result’,<Result>). If necessary, an exception is raised.

**Parallelization**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

**Possible Predecessors**

**Alternatives**

`find_shape_model, find_scaled_shape_model, find_aniso_shape_model, find_shape_models, find_scaled_shape_models, find_aniso_shape_models`

**Module**

Matching

```c
find_ncc_models ( Image : : ModelIDs, AngleStart, AngleExtent, 
  MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels : Row, 
  Column, Angle, Score, Model )
```

Find the best matches of multiple NCC models.

The operator `find_ncc_models` finds the best NumMatches instances of the NCC models that are passed in the tuple `ModelIDs` in the input `Image`. The models must have been created previously by calling
create_ncc_model or read_ncc_model. In contrast to find_ncc_model, multiple models can be searched in the same image in one call.

Characteristics of the parameter semantics

Compared to find_ncc_model, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or they must contain the same number of elements as ModelIDs, in which case each parameter element refers to the corresponding element in ModelIDs. (NumLevels may also contain either two or twice the number of elements as ModelIDs). More details can be found below in the sections containing information for the respective parameters. Note that a call to find_ncc_models with multiple values for ModelIDs, NumMatches and MaxOverlap has the same effect as multiple independent calls to find_ncc_model with the respective parameters. However, a single call to find_ncc_models is considerably more efficient.

Input parameters in detail

The image and its domain: The domain of the image Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the NCC model with create_ncc_model. A different origin set with set_ncc_model_origin is not taken into account. The model has to lie completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that rounding effects can cause matches to lie up to $0.5 \times 2^{\text{NumLevels} - 1}$ pixels outside the image.

The input Image can contain a single image object or an image object array containing multiple image objects. If Image contains a single image object, its domain is used as the region of interest for all models in ModelIDs. If Image contains multiple image objects, each domain is used as the region of interest for the corresponding model in ModelIDs. In this case, the images have to be identical except for their domains, i.e., Image cannot be constructed in an arbitrary manner using concat_obj, but must be created from the same image using add_channels or equivalent calls. If this is not the case, an error message is returned.

AngleStart and AngleExtent: The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with create_ncc_model.

Furthermore, it should be noted that in some cases instances with a rotation that is slightly outside the specified range of rotations are found. This may happen if the specified range of rotations is smaller than the range given when the model was created.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see NumLevels), it might happen that instances with a score slightly below MinScore are found.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

If NumMatches contains one element, find_ncc_models returns the best NumMatches instances of the model irrespective of the type of the model. If, for example, two models are passed in ModelIDs and NumMatches = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, NumMatches contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in NumMatches. If, for example, NumMatches = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap, only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.
If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

**SubPixel:** The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'false' the model's pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`. If `SubPixel` is set to 'true', the position as well as the rotation are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function.

**NumLevels:** The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the NCC model was created with `create_ncc_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_ncc_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_ncc_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_ncc_model_params` and then use a slightly lower value in `find_ncc_models`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of \([4,2]\) for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, `NumLevels` must contain twice the number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model. `NumLevels = \([5,2,4,1]\)` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit specification of the number of pyramid levels for the two models.

**Output parameters in detail**

**Row, Column and Angle:** The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The coordinates `Row` and `Column` are the coordinates of the origin of the NCC model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin can be set with `set_ncc_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_ncc_model` shows how to create this matrix and use it to display the model at the found position in the search image and to calculate the exact coordinates.

Note also that for visualizing the model at the found position, also the procedure `dev_display_ncc_matching_results` can be used.

**Score:** Additionally, the score of each found instance is returned in `Score`.

**Model:** The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to \(|\text{ModelIDs}| - 1\). Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`. 
Specifying a timeout

Using the operator `set_ncc_model_param` you can specify a 'timeout' for `find_ncc_models`. If the NCC models referenced by `ModelIDs` hold different values for 'timeout', `find_ncc_models` uses the smallest one. If `find_ncc_models` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by correlation-based matching, we highly recommend the usage of the procedure `dev_display_ncc_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

Note that the internally used memory increases with the number of used threads.

 Parameters

- **Image** (input_object) .........................(multichannel-)image(-array) ~ object : byte / uint2
  Input image in which the model should be found.

- **ModelIDs** (input_control) ...................... ncc_model(-array) ~ handle
  Handle of the models.

- **AngleStart** (input_control) ........................... angle.rad(-array) ~ real
  Smallest rotation of the models.
  Default value: -0.39
  Suggested values: `AngleStart` ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

- **AngleExtent** (input_control) ............................. angle.rad(-array) ~ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: `AngleExtent` ∈ {6.29, 3.14, 1.57, 0.79, 0.39, 0.0}
  Restriction: `AngleExtent` ≥ 0

- **MinScore** (input_control) ............................... real(-array) ~ real
  Minimum score of the instances of the models to be found.
  Default value: 0.8
  Suggested values: `MinScore` ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: 0 ≤ `MinScore` ≤ 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) .......................... integer(-array) ~ integer
  Number of instances of the models to be found (or 0 for all matches).
  Default value: 1
  Suggested values: `NumMatches` ∈ {0, 1, 2, 3, 4, 5, 10, 20}

- **MaxOverlap** (input_control) ............................ real(-array) ~ real
  Maximum overlap of the instances of the models to be found.
  Default value: 0.5
  Suggested values: `MaxOverlap` ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: 0 ≤ `MaxOverlap` ≤ 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **SubPixel** (input_control) ............................... string(-array) ~ string
  Subpixel accuracy if not equal to 'none'.
  Default value: 'true'
  List of values: `SubPixel` ∈ {'false', 'true'}

- **NumLevels** (input_control) ............................ integer(-array) ~ integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if |`NumLevels`| = 2).
  Default value: 0
  List of values: `NumLevels` ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **Row** (output_control) ................................. point.y-array ~ real
  Row coordinate of the found instances of the models.
18.2. CORRELATION-BASED

- **Column** (output_control) ................................................................. point.x-array \(\sim real\)
  Column coordinate of the found instances of the models.

- **Angle** (output_control) ................................................................. angle.rad-array \(\sim real\)
  Rotation angle of the found instances of the models.

- **Score** (output_control) ............................................................... real-array \(\sim real\)
  Score of the found instances of the models.

- **Model** (output_control) .............................................................. integer-array \(\sim integer\)
  Index of the found instances of the models.

--- Example ---

```plaintext
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_ncc_model (ImageReduced1, 'auto', rad(-45), rad(90), 'auto', 
    'use_polarity', ModelID1)
create_ncc_model (ImageReduced2, 'auto', rad(-45), rad(90), 'auto', 
    'use_polarity', ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_ncc_models (Image, ModelIDs, rad(-45), rad(90), 0.7, [1,1], 0.5, 
    'true', 0, Row, Column, Angle, Score, Model)
dev_display_ncc_matching_results (ModelIDs, 'red', Row, Column, 
    Angle, Model)
```

--- Result ---

If the parameter values are correct, the operator `find_ncc_models` returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via `set_system` ('no_object_result',<Result>). If necessary, an exception is raised.

--- Parallelization ---

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

**Matching**

```plaintext
get_ncc_model_origin ( : : ModelID : Row, Column )
```

*Return the origin (reference point) of an NCC model.*

The operator `get_ncc_model_origin` returns the origin (reference point) of the NCC model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. Hence, an origin of (0,0) means that the center of gravity of the domain
of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

--- Parameters ---

- **ModelID** (input_control) ........................................... ncc_model  \~ handle
  Handle of the model.
- **Row** (output_control) ........................................... point.y  \~ real
  Row coordinate of the origin of the NCC model.
- **Column** (output_control) ...................................... point.x  \~ real
  Column coordinate of the origin of the NCC model.

--- Result ---

If the handle of the model is valid, the operator `get_ncc_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

```c
get_ncc_model_params ( : : ModelID : NumLevels, AngleStart,
                      AngleExtent, AngleStep, Metric )
```

Return the parameters of an NCC model.

The operator `get_ncc_model_params` returns the parameters of the NCC model `ModelID` that were used to create it using `create_ncc_model`. In particular, this output can be used to check the parameters `NumLevels` and `AngleStep` if they were determined automatically during the model creation with `create_ncc_model`. Furthermore, this output can be used to check the parameters if the model was read with `read_ncc_model`.

--- Parameters ---

- **ModelID** (input_control) ........................................... ncc_model  \~ handle
  Handle of the model.
- **NumLevels** (output_control) .................................... integer  \~ integer
  Number of pyramid levels.
- **AngleStart** (output_control) ................................... angle.rad  \~ real
  Smallest rotation of the pattern.
- **AngleExtent** (output_control) ................................... angle.rad  \~ real
  Extent of the rotation angles.
  **Assertion:** AngleExtent >= 0
- **AngleStep** (output_control) ................................... angle.rad  \~ real
  Step length of the angles (resolution).
  **Assertion:** AngleStep >= 0
- **Metric** (output_control) ....................................... string  \~ string
  Match metric.
18.2. CORRELATION-BASED

Result

If the handle of the model is valid, the operator `get_ncc_model_params` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

find_ncc_model

Module

Matching

get_ncc_model_region ( : ModelRegion : ModelID : )

Return the region used to create an NCC model.

The operator `get_ncc_model_region` returns the region used to create the NCC model `ModelID` in `ModelRegion`. This region can be used, for example, to visualize the found instances of the model in an image. It should be noted that the position of `ModelRegion` is normalized such that the reference point of the model (see `set_ncc_model_origin`) lies at the pixel position (0, 0). Hence, the region simply needs to be translated to the found position in the image (and possibly rotated around this point). `get_ncc_model_region` ignores the value of the system parameter ‘clip_region’.

Parameters

- `ModelRegion` (output_object) - Model region of the NCC model.
- `ModelID` (input_control) - Handle of the model.

Result

If the handle of the NCC model is valid, the operator `get_ncc_model_region` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_ncc_model

Module

Matching

read_ncc_model ( : : FileName : ModelID )

Read an NCC model from a file.

The operator `read_ncc_model` reads an NCC model, which has been written with `write_ncc_model`, from the file `FileName`. The default HALCON file extension for the NCC model is `ncm`. 
### Parameters

- **FileName** (input_control) ................................................................. filename.read  \(\rightarrow\) string
  
  File name.

- **ModelID** (output_control) ............................................................... ncc_model  \(\rightarrow\) handle
  
  Handle of the model.

### Result

If the file name is valid, the operator `read_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Successors

- `fwrite_serialized_item, send_serialized_item, deserialize_ncc_model`

### Module

Matching

---

**serialize_ncc_model** ( : : ModelID : SerializedItemHandle )

Serialize an NCC model.

`serialize_ncc_model` serializes the data of an NCC model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ncc_model` is converted to a serialized item. The NCC model is defined by the handle `ModelID`. The serialized NCC model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ncc_model`.
set_ncc_model_origin ( : : ModelID, Row, Column : )

Set the origin (reference point) of an NCC model.

The operator set_ncc_model_origin sets the origin (reference point) of the NCC model ModelID to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the NCC model with create_ncc_model. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ModelID (input_control) ncc_model ~ handle
  Handle of the model.
- Row (input_control) point.y ~ real
  Row coordinate of the origin of the NCC model.
- Column (input_control) point.x ~ real
  Column coordinate of the origin of the NCC model.

Result

If the handle of the model is valid, the operator set_ncc_model_origin returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

area_center

Module

set_ncc_model_param ( : : ModelID, GenParamName, GenParamValue : )

Set selected parameters of the NCC model.

The operator set_ncc_model_param sets the selected parameters GenParamName in the NCC model ModelID. The following parameters can be modified:

- 'timeout'

  Sets the maximum runtime of the operators used to find the NCC model ModelID (using find_ncc_model). This is especially useful in cases where a maximum cycle time has to be ensured. The 'timeout' must be given in milliseconds. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the 'timer_mode' set via set_system. Be aware that the runtime of the search increases by up to 10 percent with activated timeout. To disable the timeout you can either use a negative value or 'false'.
Parameters

- **ModelID** (input_control) \( \rightsquigarrow \text{ncc\_model} \) \( \rightsquigarrow \text{handle} \)
  Handle of the model.
- **GenParamName** (input_control) \( \rightsquigarrow \text{attribute\_name\_array} \) \( \rightsquigarrow \text{string} \)
  Parameter names.
  - **List of values:** GenParamName \( \in \{ \text{’timeout’} \} \)
- **GenParamValue** (input_control) \( \rightsquigarrow \text{attribute\_value\_array} \) \( \rightsquigarrow \text{real} / \text{integer} / \text{string} \)
  Parameter values.

Result

If the parameters are valid, the operator `set_ncc_model_param` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Matching

**write_ncc_model** ( : : ModelID, FileName : )

Write an NCC model to a file.

The operator `write_ncc_model` writes an NCC model to the file `FileName`. The model can be read again with `read_ncc_model`. The default HALCON file extension for the NCC model is ‘ncm’.

Parameters

- **ModelID** (input_control) \( \rightsquigarrow \text{ncc\_model} \) \( \rightsquigarrow \text{handle} \)
  Handle of the model.
- **FileName** (input_control) \( \rightsquigarrow \text{filename\_write} \) \( \rightsquigarrow \text{string} \)
  File name.
  - **File extension:** .ncm

Result

If the file name is valid (write permission), the operator `write_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

18.3 Deformable

**clear_deformable_model** ( : : ModelID : )

Free the memory of a deformable model.

The operator `clear_deformable_model` frees the memory of a deformable model that was created by `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model`. After calling `clear_deformable_model`, the deformable model can no longer be used. The handle `ModelID` becomes invalid.

---

**Parameters**

- ModelID (input_control) ......................... deformable_model(-array) ~ handle
  Handle of the model.

---

**Result**

If the parameters are valid, the operator `clear_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Module**

Matching

---

**create_local_deformable_model** ( Template : : NumLevels,
  AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,
  ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,
  Metric, Contrast, MinContrast, GenParamName,
  GenParamValue : ModelID )

Creates a deformable model for local, deformable matching.

The operator `create_local_deformable_model` prepares a template, which is passed in the image `Template`, as a deformable model used for local deformable matching. The ROI of the model is passed as the domain of `Template`.

The local deformable matching can be used to detect an object that is distorted by a local deformation. This is similar to `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model` which require that the object is rigid. Further, it is an alternative to the mode ’max_deformation’ in `find_shape_model`. Here, the model remains rigid but is able to tolerate small deformations. In contrast to `find_shape_model`, `create_local_deformable_model` can be used to estimate the deformation and rectify the image area where the object is found. Further, `create_local_deformable_model` can cope with bigger deformations.

As described in `create_planar_uncalib_deformable_model`, the origin (reference point) of the model is defined as the center of gravity of the domain (region) of the model image `Template`. Further, the axis-aligned
enclosing rectangle of the domain of the Template is used to determine the area of the search image that is rectified in calls of find_local_deformable_model.

For further explanation on the parameters used for the creation of a local deformable model we refer to the description of create_planar_uncalib_deformable_model. Note, that the parameters of the actual deformation are set with the call of find_local_deformable_model.

Parameters

- **Template** (input_object) ................................. (multichannel-)image  ~ object : byte / uint2
  Input image whose domain will be used to create the model.
- **NumLevels** (input_control) .............................. integer  ~ integer / string
  Maximum number of pyramid levels.
  Default value: ’auto’
  List of values: NumLevels ∈ ['auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
- **AngleStart** (input_control) .............................. angle.rad-array  ~ real
  This parameter is not used.
  Default value: []
- **AngleExtent** (input_control) .............................. angle.rad-array  ~ real
  This parameter is not used.
  Default value: []
- **AngleStep** (input_control) .............................. angle.rad  ~ real / string
  Step length of the angles (resolution).
  Default value: ’auto’
  Suggested values: AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]
  Restriction: AngleStep > 0 && AngleStep <= pi / 16
- **ScaleRMin** (input_control) .............................. number  ~ real
  Minimum scale of the pattern in row direction.
  Default value: 1.0
  Suggested values: ScaleRMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: ScaleRMin > 0
- **ScaleRMax** (input_control) .............................. number-array  ~ real
  This parameter is not used.
  Default value: []
- **ScaleRStep** (input_control) .............................. number  ~ real / string
  Scale step length (resolution) in row direction.
  Default value: ’auto’
  Suggested values: ScaleRStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleRStep >= 0
- **ScaleCMin** (input_control) .............................. number  ~ real
  Minimum scale of the pattern in column direction.
  Default value: 1.0
  Suggested values: ScaleCMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: ScaleCMin > 0
- **ScaleCMax** (input_control) .............................. number-array  ~ real
  This parameter is not used.
  Default value: []
- **ScaleCStep** (input_control) .............................. number  ~ real / string
  Scale step length (resolution) in column direction.
  Default value: ’auto’
  Suggested values: ScaleCStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleCStep >= 0
- **Optimization** (input_control) .............................. string(-array)  ~ string
  Kind of optimization used for generating the model.
  Default value: ’none’
  List of values: Optimization ∈ ['auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high']
**18.3. DEFORMABLE**

- **Metric** (input_control) ................................. string ~ string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric ∈ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}

- **Contrast** (input_control) ............................... number-array ~ integer / string
  Thresholds or hysteresis thresholds for the contrast of the object in the template image.
  Default value: 'auto'
  Suggested values: Contrast ∈ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}

- **MinContrast** (input_control) ........................... number ~ integer / string
  Minimum contrast of the objects in the search images.
  Default value: 'auto'
  Suggested values: MinContrast ∈ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
  Restriction: MinContrast < Contrast

- **GenParamName** (input_control) ........................... string-array ~ string
  The generic parameter names.
  Default value: []
  List of values: GenParamName ∈ {[], 'min_size', 'part_size'}

- **GenParamValue** (input_control) ........................... integer-array ~ integer / real / string
  Values of the generic parameters.
  Default value: []
  List of values: GenParamValue ∈ {[], 'small', 'medium', 'big'}

- **ModelID** (output_control) ................................. deformable_model ~ handle
  Handle of the model.

**Result**

If the parameters are valid, the operator create_local_deformable_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

```hfp
create_local_deformable_model_xld ( Contours : : NumLevels,
  AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,
  ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,
  Metric, MinContrast, GenParamName, GenParamValue : ModelID )
```

Prepare a deformable model for local deformable matching from XLD contours.
The operator `create_local_deformable_model_xld` creates a deformable model used for local deformable matching from the XLD contours passed in `Contours`. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator `create_local_deformable_model`, which creates a deformable model from a template image, the operator `create_local_deformable_model_xld` creates the deformable model from XLD contours.

The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_deformable_model_origin`.

For further explanation on the deformable model and its parameters we refer to the description of `create_planar_uncalib_deformable_model` and `create_local_deformable_model`. Note that `set_local_deformable_model_metric` can be used to change the metric of the model.

---

**Attention**

Note that, in contrast to the operator `create_local_deformable_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated with the operator `select_contours_xld` before calling `create_local_deformable_model_xld`.

---

**Parameters**

- **Contours** (input_object) `xld_cont(-array)` → object
  Input contours that will be used to create the model.

- **NumLevels** (input_control) `integer` → integer / string
  Maximum number of pyramid levels.
  Default value: "auto"
  List of values: `NumLevels ∈ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}`

- **AngleStart** (input_control) `angle.rad-array` → real
  This parameter is not used.
  Default value: []

- **AngleExtent** (input_control) `angle.rad-array` → real
  This parameter is not used.
  Default value: []

- **AngleStep** (input_control) `angle.rad` → real / string
  Step length of the angles (resolution).

**Module**

Matching
create_planar_calib_deformable_model ( Template : : CamParam, ReferencePose, NumLevels, AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, Contrast, MinContrast, GenParamName, GenParamValue : ModelID )

Create a deformable model for calibrated perspective matching.

The operator create_planar_calib_deformable_model prepares a template, which is passed in the image Template, as a deformable model used for planar calibrated matching. The ROI of the model is passed as the domain of Template.

The planar calibrated matching can be used to detect the 3D pose of a planar object or planar subparts of non-planar objects that are distorted by a projective view. This is an alternative to create_planar_uncalib_deformable_model, which returns the position as a 2D projective transformation (homography), but not as a metric 3D pose.

In order to determine the 3D pose, the internal camera parameters CamParam must be provided. Typically, the internal parameters are determined with the help of calibrate_cameras.

Additionally to the internal camera parameters, the metric size of the image part that is passed in Template must be known. For this, a 3D reference pose that defines a 3D model plane in which the object resides must be provided with ReferencePose. The 3D model plane is spanned by the x and y axis of the coordinate system defined by ReferencePose.

As described in create_planar_uncalib_deformable_model, the origin (reference point) of the model is defined as the center of gravity of the domain (region) of the model image Template. This image point defines a ray that is cut with the plane that is provided with ReferencePose to obtain the absolute 3D model pose. This is also the absolute pose that is later returned in find_planar_calib_deformable_model. Hence, the 3D pose of the model might differ from the reference pose by a 2D translation in the model plane. The final model pose can be determined by calling get_deformable_model_params. The 3D model plane can be estimated by using calibrate_cameras or vector_to_pose. For consistency of the coordinate systems, the ReferencePose should be aligned as if a calibration plate would be put onto the object.

For further explanation on the planar deformable model and its parameters we refer to the description of create_planar_uncalib_deformable_model.

Parameters

- **Template** (input_object) ........................................... (multichannel-)image  \( \sim \) object : byte / uint2
  Input image whose domain will be used to create the model.

- **CamParam** (input_control) ............................................ campar  \( \sim \) real / integer / string
  The parameters of the internal orientation of the camera.

- **ReferencePose** (input_control) ................................... pose  \( \sim \) real / integer
  The reference pose of the object in the reference image.

- **NumLevels** (input_control) ........................................ integer  \( \sim \) integer / string
  Maximum number of pyramid levels.
  **Default value:** ‘auto’
  **List of values:** NumLevels \( \in \) [‘auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

- **AngleStart** (input_control) ........................................ angle.rad-array  \( \sim \) real
  This parameter is not used.
  **Default value:** []

- **AngleExtent** (input_control) ...................................... angle.rad-array  \( \sim \) real
  This parameter is not used.
  **Default value:** []

- **AngleStep** (input_control) ........................................... angle.rad  \( \sim \) real / string
  Step length of the angles (resolution).
  **Default value:** ‘auto’
  **Suggested values:** AngleStep \( \in \) [‘auto’, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]
  **Restriction:** AngleStep > 0 \&\& AngleStep <= \pi / 16

create_planar_calib_deformable_model_xld (  
Contours : : CamParam, ReferencePose, NumLevels, AngleStart, 
AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep, 
ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, 
MinContrast, GenParamName, GenParamValue : ModelID )

Prepare a deformable model for planar calibrated matching from XLD contours.

The operator create_planar_calib_deformable_model_xld creates a deformable model used for planar calibrated matching from the XLD contours passed in Contours. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator create_planar_calib_deformable_model, which creates a deformable model from a template image, the operator create_planar_calib_deformable_model_xld creates the deformable model from XLD contours. Note that the operator expects Contours to be in a metric world coordinate system. This is in contrast to create_planar_uncalib_deformable_model_xld, where the Contours are provided in image coordinates.

Further, the origin (reference point) of the model is taken directly from the provided Contours. This is in contrast to create_planar_uncalib_deformable_model_xld, where the center of gravity of the smallest surrounding rectangle of the Contours that is parallel to the coordinate axes is used. A different origin in the world coordinate system can be set with set_deformable_model_origin.

For further explanation on the planar deformable model and its parameters we refer to the description of create_planar_uncalib_deformable_model and create_planar_calib_deformable_model.

Attention

Note that, in contrast to the operator create_planar_calib_deformable_model, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated before calling create_planar_calib_deformable_model_xld with the operator select_contours_xld.

Parameters

- **Contours** (input_object) .......................................................xld_cont(-array) ~ object
  Input contours that will be used to create the model.
- **CamParam** (input_control) ..............................................campar ~ real / integer / string
  The parameters of the internal orientation of the camera.
18.3. DEFORMABLE

- **ReferencePose** (input_control) ........................................... pose \(\rightarrow\) real / integer

Metric, Contrast, MinContrast, GenParamName,
GenParamValue : ModelID )

Creates a deformable model for uncalibrated, perspective matching.

The operator create_planar_uncalib_deformable_model prepares a template, which is passed in the image Template, as a deformable model used for uncalibrated perspective matching. The ROI of the model is passed as the domain of Template.

The planar uncalibrated matching can be used to detect planar objects or planar subparts of non-planar objects that are distorted by a projective view.

This is an alternative to create_shape_model, create_scaled_shape_model and create_aniso_shape_model, where typically the search image must be rectified by calibrate_cameras and gen_image_to_world_plane_map beforehand.

In contrast to create_shape_model_3d there is no need to pre-generate different views of an object, resulting into a smaller memory consumption. Hence, in case of a planar perspective distorted object, create_planar_uncalib_deformable_model should be preferred.

The model is generated using multiple image pyramid levels and is stored in memory. The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_planar_uncalib_deformable_model.

Input parameters in detail
NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_planar_uncalib_deformable_model` returns with an error message. If `NumLevels` is set to `'auto'`, `create_planar_uncalib_deformable_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_deformable_model_params`. In rare cases, it might happen that `create_planar_uncalib_deformable_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in `find_planar_uncalib_deformable_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_planar_uncalib_deformable_model` increases. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

Angle and Scale parameters: Note that the parameters `AngleStart`, `AngleExtent`, `ScaleRMax`, and `ScaleCMax` are not used by this operator. Instead, they have to be specified within the operator `find_planar_uncalib_deformable_model`. `ScaleRMin` and `ScaleCMin` can be relevant if you expect matches that are smaller than in the original image Template. Then, if `NumLevels` is set to `'auto'`, the number of used pyramid levels may decrease. Generally, the parameters `AngleStep`, `ScaleRStep` and `ScaleCStep` can be determined automatically. The automatically computed angle and scale step lengths can be queried using `get_deformable_model_params`. For more information about how these parameters work, please refer to the operator `find_planar_uncalib_deformable_model`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from `'none'`. If Optimization = `'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in `find_planar_uncalib_deformable_model` to set the parameter Score and Greediness to a smaller value. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined. If Optimization is set to `'auto'`, `create_planar_uncalib_deformable_model` automatically determines the reduction of the number of model points.

Contrast: The parameter `Contrast` determines the contrast the model points (edges) must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model.

The following values can be set for `Contrast`:

- A single contrast value. You can set:
  - an integer value: the manually determined value is used.
  - `'auto_contrast'`: the contrast value is computed automatically.

- Hysteresis thresholds. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. For more information about the hysteresis threshold method, see `hysteresis_threshold`. You can set:
  - A tuple of two values: The first value determines the lower threshold, the second value determines the upper threshold.
  - `'auto'` (default value) or `'auto_contrast_hyst'`: The hysteresis thresholds are computed automatically.

In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_deformable_model_params` and subsequently verified using `inspect_shape_model` before calling `create_planar_uncalib_deformable_model`. Note
that $\text{MinContrast}$ influences the automatic contrast estimation, and hence also the estimation of the minimum size.

**MinContrast:** With $\text{MinContrast}$, it can be determined which minimal contrast the model must have in the recognition performed by $\text{find_planar_uncalib_deformable_model}$. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, $\text{MinContrast}$ should be set to 10. Obviously, $\text{MinContrast}$ must be smaller than $\text{Contrast}$. If the model should be recognized in very low contrast images, $\text{MinContrast}$ must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, $\text{MinContrast}$ should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by $\text{find_planar_uncalib_deformable_model}$. If $\text{MinContrast}$ is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using $\text{get_deformable_model_params}$. The $\text{MinContrast}$ of a deformable model can later be changed with the help of $\text{set_deformable_model_param}$.

**Metric:** The parameter $\text{Metric}$ determines the conditions under which the model is recognized in the image. If $\text{Metric} = \text{use_polarity}$, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If $\text{Metric} = \text{ignore_global_polarity}$, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of $\text{find_planar_uncalib_deformable_model}$ will increase slightly in this case. If $\text{Metric} = \text{ignore_part_polarity}$, the contrast polarity is allowed to change only between different parts of the model, whereas the polarity of model points that are within the same model part must not change. Please note that the term 'ignore_part_polarity' is capable of being misunderstood. It means that polarity changes between neighboring model parts do not influence the score, and hence are ignored. If $\text{Metric} = \text{ignore_local_polarity}$, the model is found even if the contrast changes for each individual model point. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. In this case the runtime of $\text{find_planar_uncalib_deformable_model}$ increases significantly. The above four metrics can only be applied to single-channel images. If a multi-channel image is used as the model image or as the search image only the first channel will be used (and no error message will be returned). If $\text{Metric} = \text{ignore_color_polarity}$, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of $\text{find_planar_uncalib_deformable_model}$ can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for $\text{Metric} = \text{ignore_color_polarity}$ the number of channels in the model creation with $\text{create_planar_uncalib_deformable_model}$ and in the search with $\text{find_planar_uncalib_deformable_model}$ can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

**GenParamName, GenParamValue:** With the help of the generic parameters $\text{GenParamName}$ and $\text{GenParamValue}$, the user can set parameters for the deformable model generation that are needed only in rare cases. Currently, it is used to adapt the average size of the sub-parts that the deformable model should consist of. Here, $\text{GenParamName}$ should be set to 'part_size' and $\text{GenParamValue}$ should be set to 'small', 'medium' or 'big'. For objects that consist of many small contours, 'small' should be selected. For objects that consist of only big contours, 'big' should be set. The default value of this parameter is 'big'.

Optionally, $\text{GenParamName} = \text{min_size}$ can determine a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size specified in the corresponding $\text{GenParamValue}$ are suppressed. This threshold for the minimum size is divided by two for each successive pyramid level. $\text{min_size}$ can be set to an arbitrary integer value greater or equal 0. It can also be set to 'auto' which means that the minimum size will be determined automatically. The default value of this parameter is 'auto'.
The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin for the model can be set with `set_deformable_model_origin`.

### Parameters

- **Template** (input_object) .................................................. (multichannel-)image \(\sim\) object : byte / uint2
  Input image whose domain will be used to create the model.
- **NumLevels** (input_control) .............................................. integer \(\sim\) integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: `NumLevels` ∈ \{'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}
- **AngleStart** (input_control) ............................................. angle.rad-array \(\sim\) real
  This parameter is not used.
  Default value: []
- **AngleExtent** (input_control) ........................................... angle.rad-array \(\sim\) real
  This parameter is not used.
  Default value: []
- **AngleStep** (input_control) ............................................. angle.rad \(\sim\) real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: `AngleStep` ∈ \{'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\}
  Restriction: `AngleStep > 0 && AngleStep <= \pi / 16`
- **ScaleRMin** (input_control) ............................................ number \(\sim\) real
  Minimum scale of the pattern in row direction.
  Default value: 1.0
  Suggested values: `ScaleRMin` ∈ \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Restriction: `ScaleRMin > 0`
- **ScaleRMax** (input_control) ............................................ number-array \(\sim\) real
  This parameter is not used.
  Default value: []
- **ScaleRStep** (input_control) ......................................... number \(\sim\) real / string
  Scale step length (resolution) in row direction.
  Default value: 'auto'
  Suggested values: `ScaleRStep` ∈ \{'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2\}
  Restriction: `ScaleRStep >= 0`
- **ScaleCMin** (input_control) ............................................ number \(\sim\) real
  Minimum scale of the pattern in column direction.
  Default value: 1.0
  Suggested values: `ScaleCMin` ∈ \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Restriction: `ScaleCMin > 0`
- **ScaleCMax** (input_control) ............................................ number-array \(\sim\) real
  This parameter is not used.
  Default value: []
- **ScaleCStep** (input_control) ......................................... number \(\sim\) real / string
  Scale step length (resolution) in column direction.
  Default value: 'auto'
  Suggested values: `ScaleCStep` ∈ \{'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2\}
  Restriction: `ScaleCStep >= 0`
- **Optimization** (input_control) ....................................... string(-array) \(\sim\) string
  Kind of optimization used for generating the model.
  Default value: 'none'
  List of values: `Optimization` ∈ \{'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'\}
- **Metric** (input_control) ................................................ string \(\sim\) string
  Match metric.
  Default value: 'use_polarity'
  List of values: `Metric` ∈ \{'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'\}
Contrast (input_control) .............................. number-array  \sim integer / string
Thresholds or hysteresis thresholds for the contrast of the object in the template image.
Default value: 'auto'
Suggested values: Contrast \in \{ 'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160 \}

MinContrast (input_control) .............................. number  \sim integer / string
Minimum contrast of the objects in the search images.
Default value: 'auto'
Suggested values: MinContrast \in \{ 'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40 \}
Restriction: MinContrast < Contrast

GenParamName (input_control) .............................. string-array  \sim string
The generic parameter names.
Default value: []
List of values: GenParamName \in \{ [], 'min_size', 'part_size' \}

GenParamValue (input_control) .............................. integer-array  \sim integer / real / string
Values of the generic parameter.
Default value: []
List of values: GenParamValue \in \{ [], 'small', 'medium', 'big' \}

ModelID (output_control) .............................. deformable_model  \sim handle
Handle of the model.

Result
If the parameters are valid, the operator create_planar_uncalib_deformable_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

GenParamValue : ModelID )

Prepare a deformable model for planar uncalibrated matching from XLD contours.

The operator create_planar_uncalib_deformable_model_xld creates a deformable model used for planar uncalibrated matching from the XLD contours passed in Contours. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator create_planar_uncalib_deformable_model, which creates a deformable model from a template image, the operator create_planar_uncalib_deformable_model_xld creates the deformable model from XLD contours.
The model is generated for multiple image pyramid levels and is stored in memory. The center of gravity of the smallest surrounding rectangle of the Contours that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with set_deformable_model_origin. The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_planar_uncalib_deformable_model.

Some Input parameters in detail

**NumLevels**: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure leads to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_planar_uncalib_deformable_model_xld returns with an error message. If NumLevels is set to 'auto', create_planar_uncalib_deformable_model_xld determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using get_deformable_model_params. In rare cases, it might happen that create_planar_uncalib_deformable_model_xld determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the search image or it may be necessary to select very low parameters for MinScore or Greediness in find_planar_uncalib_deformable_model to find the object. If the number of pyramid levels is chosen too small, the time required to find the object with find_planar_uncalib_deformable_model may increase. In both cases, the number of pyramid levels should be selected manually.

**Angle and Scale parameters**: Note that the parameters AngleStart, AngleExtent, ScaleRMax, and ScaleCMax are not used by this operator. Instead, they have to be specified within the operator find_planar_uncalib_deformable_model. ScaleRMin and ScaleCMin can be relevant if you expect matches that are smaller than the given XLD Contours. Then, if NumLevels is set to 'auto', the number of used pyramid levels may decrease.

Generally, the parameters AngleStep, ScaleRStep and ScaleCStep can be determined automatically. The automatically computed angle and scale step lengths can be queried using get_deformable_model_params. For more information about how these parameters work, please refer to the operator find_planar_uncalib_deformable_model.

**Optimization**: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none' is set, all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_planar_uncalib_deformable_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search, because in this case usually significantly more potential instances of the model must be examined. If Optimization is set to 'auto', create_planar_uncalib_deformable_model_xld automatically determines the reduction of the number of model points.

**MinContrast**: With MinContrast, it can be determined which contrast the object contours must at least have in the recognition performed by find_planar_uncalib_deformable_model. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray-value changes caused by the noise in the image. If, e.g., the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multi-channel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see below) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, e.g., the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image, MinContrast should be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise to ensure that the position and rotation of the model are extracted robustly and accurately by find_planar_uncalib_deformable_model.

**Metric**: The parameter Metric determines the conditions under which the model is recognized in the image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the noise.
background. If $\text{Metric} = '\text{ignore\_global\_polarity}'$, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of \texttt{find\_planar\_uncalib\_deformable\_model} will increase slightly in this case. If $\text{Metric} = '\text{ignore\_part\_polarity}'$ or $\text{Metric} = '\text{ignore\_local\_polarity}'$, the model is found even if the contrast changes locally. These modes can, e.g., be useful if the object consists of a part with a medium gray value, within which either darker or brighter sub-objects lie. The above mentioned four metrics can only be applied to single-channel images. If a multi-channel image is used as the search image, only the first channel will be used (and no error message will be returned). If $\text{Metric} = '\text{ignore\_color\_polarity}'$, the model is found even if the color contrast changes locally. This is, e.g., the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of \texttt{find\_planar\_calib\_deformable\_model} can also increase significantly. The metric $'\text{ignore\_color\_polarity}'$ can be used for images with an arbitrary number of channels. If it is used for single-channel images, it has the same effect as $'\text{ignore\_local\_polarity}'$. It should be noted that for $\text{Metric} = '\text{ignore\_color\_polarity}'$ the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, e.g., also contain images of the same object that were obtained by illuminating the object from different directions. Note that the first two metrics ($'\text{use\_polarity}'$ and $'\text{ignore\_global\_polarity}'$) can only be selected if all \texttt{Contours} provide the attribute $'\text{edge\_direction}'$, which defines the polarity of the contained contours. For more information about contour attributes like $'\text{edge\_direction}'$ see \texttt{get\_contour\_attrib\_xld}. Otherwise, these two metrics can be selected with the operator \texttt{set\_planar\_uncalib\_deformable\_model\_metric}, which determines the polarity of the model contours from a representative image.

**Attention**

Note that, in contrast to the operator \texttt{create\_planar\_uncalib\_deformable\_model}, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated before calling \texttt{create\_planar\_uncalib\_deformable\_model\_xld} with the operator \texttt{select\_contours\_xld}.

**Parameters**

- **Contours** (input_object) \(\ldots\) \texttt{xld\_cont\_array} \(\sim\) \texttt{object}
  
  Input contours that will be used to create the model.

- **NumLevels** (input_control) \(\ldots\) \texttt{integer} \(\sim\) \texttt{integer/string}
  
  Maximum number of pyramid levels.
  
  Default value: 'auto'
  
  Suggested values: \(\text{NumLevels} \in \{\text{\textquoteleft auto\textquoteright}, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}\)

- **AngleStart** (input_control) \(\ldots\) \texttt{angle/real} \(\sim\) \texttt{real}
  
  This parameter is not used.
  
  Default value: []

- **AngleExtent** (input_control) \(\ldots\) \texttt{angle/real} \(\sim\) \texttt{real}
  
  This parameter is not used.
  
  Default value: []

- **AngleStep** (input_control) \(\ldots\) \texttt{angle/real} \(\sim\) \texttt{real/string}
  
  Step length of the angles (resolution).
  
  Default value: 'auto'
  
  Suggested values: \(\text{AngleStep} \in \{\text{\textquoteleft auto\textquoteright}, \, 0.0175, \, 0.0349, \, 0.0524, \, 0.0698, \, 0.0873\}\)
  
  Restriction: \(\text{AngleStep} > 0 \quad \&\& \quad \text{AngleStep} \leq \pi / 16\)

- **ScaleRMin** (input_control) \(\ldots\) \texttt{number} \(\sim\) \texttt{real}
  
  Minimum scale of the pattern in row direction.
  
  Default value: 1.0
  
  Suggested values: \(\text{ScaleRMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  
  Restriction: \(\text{ScaleRMin} > 0\)

- **ScaleRMax** (input_control) \(\ldots\) \texttt{number-array} \(\sim\) \texttt{real}
  
  This parameter is not used.
  
  Default value: []

- **ScaleRStep** (input_control) \(\ldots\) \texttt{number} \(\sim\) \texttt{real/string}
  
  Scale step length (resolution) in row direction.
  
  Default value: 'auto'
  
  Suggested values: \(\text{ScaleRStep} \in \{\text{\textquoteleft auto\textquoteright}, \, 0.01, \, 0.02, \, 0.05, \, 0.1, \, 0.15, \, 0.2\}\)
  
  Restriction: \(\text{ScaleRStep} > 0\)
18.3. DEFORMABLE

- **ScaleCMin** (input_control) .......................... number $\rightarrow$ real
  Minimum scale of the pattern in column direction.
  Default value: 1.0
  Suggested values: ScaleCMin $\in$ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: ScaleCMin > 0

- **ScaleCMax** (input_control) .......................... number-array $\rightarrow$ real
  This parameter is not used.
  Default value: []

- **ScaleCStep** (input_control) .......................... number $\rightarrow$ real / string
  Scale step length (resolution) in the column direction.
  Default value: 'auto'
  Suggested values: ScaleCStep $\in$ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleCStep > 0

- **Optimization** (input_control) ......................... string(-array) $\rightarrow$ string
  Kind of optimization used for generating the model.
  Default value: 'auto'
  List of values: Optimization $\in$ ['auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high']

- **Metric** (input_control) .............................. string $\rightarrow$ string
  Match metric.
  Default value: 'ignore_local_polarity'
  List of values: Metric $\in$ ['use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity']

- **MinContrast** (input_control) ........................ number $\rightarrow$ integer
  Minimum contrast of the objects in the search images.
  Default value: 5
  Suggested values: MinContrast $\in$ [1, 2, 3, 5, 7, 10, 20, 30, 40]

- **GenParamName** (input_control) ....................... string-array $\rightarrow$ string
  The generic parameter names.
  Default value: []
  List of values: GenParamName $\in$ [{}], 'part_size'

- **GenParamValue** (input_control) ...................... integer-array $\rightarrow$ integer / real / string
  Values of the generic parameters.
  Default value: []
  List of values: GenParamValue $\in$ [{}], 'small', 'medium', 'big'

- **ModelID** (output_control) .......................... deformable_model $\rightarrow$ handle
  Handle of the model.

--- Result ---

If the parameters are valid, the operator `create_planar_uncalib_deformable_model_xld` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Chapter 18 Matching

**Module**

**Deserialize deformable model**

`deserialize_deformable_model` ( : : SerializedItemHandle : ModelID )

Deserializes a deformable model.

`deserialize_deformable_model` deserializes a deformable model, that was serialized by `serialize_deformable_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized deformable model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created deformable model with the handle `ModelID`.

**Parameters**

- `SerializedItemHandle` (input_control) ............................... serialized_item ˜ handle
  Handle of the serialized item.
- `ModelID` (output_control) .............................................. deformable_model ˜ handle
  Handle of the model.

**Result**

If the parameters are valid, the operator `deserialize_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

**Determine deformable model params**

`determine_deformable_model_params` ( Template : : NumLevels, AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization, Metric, Contrast, MinContrast, GenParamName, GenParamValue, Parameters : ParameterName, ParameterValue )

Determines certain parameters of a deformable model automatically from the model image `Template`. The parameters to be determined can be specified with `Parameters`. `determine_deformable_model_params` can be used to determine the same parameters that are determined automatically when the respective parameter in `create_planar_uncalib_deformable_model` is set to ‘auto’: the number of pyramid levels (`Parameters = 'num_levels'`), the angle step length (`Parameters = 'angle_step'`), the scale step length (`Parameters = 'scale_step'` for isotropic scaling and `'scale_r_step'` and/or `'scale_c_step'` for anisotropic scaling), the kind of optimization (`Parameters = 'optimization'`), the threshold (`Parameters = 'contrast'`) or the hysteresis thresholds (`Parameters = 'contrast_hyst'`) for the contrast, the minimum size of the object parts (`Parameters = 'min_size'`), and the minimum contrast (`Parameters = 'min_contrast'`).
'min_contrast' ). By passing a tuple of the above values in Parameters, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed. In this case both hysteresis thresholds are determined, i.e., the operator behaves like passing 'contrast_hyst' instead of 'contrast'.

determine_deformable_model_params is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in ParameterName and ParameterValue. The parameter names in ParameterName are identical to the names in Parameters, where, of course, the value 'all' is replaced by the actual parameter names. An exception is the parameter 'contrast_hyst', for which the two values 'contrast_low' and 'contrast_high' are returned.

The remaining parameters (NumLevels, AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization, Metric, Contrast, and MinContrast) have the same meaning as in create_planar_uncalib_deformable_model and find_planar_uncalib_deformable_model. The description of these parameters can be looked up with these operators. These parameters are used by determine_deformable_model_params to calculate the parameters to be determined in the same manner as in create_planar_uncalib_deformable_model. It should be noted that if the parameters of a deformable model with isotropic scaling should be determined, i.e., if Parameters contains 'scale_step' either explicitly or implicitly via 'all', the parameters ScaleMin and ScaleMax must contain one value each. If the parameters of a deformable model with anisotropic scaling should be determined, i.e., if Parameters contains 'scale_r_step' or 'scale_c_step' either explicitly or implicitly, the parameters ScaleMin and ScaleMax must contain two values each. In this case, the first value of the respective parameter refers to the scaling in row direction, while the second value refers to scaling in the column direction.

Note that in determine_deformable_model_params some parameters appear that can also be determined automatically (NumLevels, Optimization, Contrast, MinContrast). If these parameters should not be determined automatically, i.e., their name is not passed in ParameterName, the corresponding parameters must contain valid values and must not be set to 'auto'. In contrast, if these parameters are to be determined automatically, their values are treated in the following way: If the optimization or the (hysteresis) contrast is to be determined automatically, i.e., ParameterName contains the value 'optimization' or 'contrast' ('contrast_hyst'), the values passed in Optimization and Contrast are ignored. In contrast, if the maximum number of pyramid levels or the minimum contrast is to be determined automatically, i.e., ParameterName contains the value 'num_levels' or 'min_contrast', you can let HALCON determine suitable values and at the same time specify an upper or lower boundary, respectively:

If the maximum number of pyramid levels should be specified in advance, NumLevels can be set to the particular value. If in this case Parameters contains the value 'num_levels', the computed number of pyramid levels is at most NumLevels. If NumLevels is set to 'auto' (or 0 for backwards compatibility), the number of pyramid levels is determined without restrictions as large as possible.

If the minimum contrast should be specified in advance, MinContrast can be set to the particular value. If in this case Parameters contains the value 'min_contrast', the computed minimum contrast is at least MinContrast. If MinContrast is set to 'auto', the minimum contrast is determined without restrictions.

If the user wishes to create a calibrated, deformable model with create_planar_calib_deformable_model, the internal camera parameters are needed for the correct estimation of the parameters in ParameterValue. The camera parameters can be provided by setting GenParamName to 'cam_param' and providing the tuple containing the camera parameters in GenParamValue.

---

Parameters

- **Template** (input_object) ............................... (multichannel-)image ∼ object : byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) ................................. integer ∼ integer / string
  Maximum number of pyramid levels.

  Default value: 'auto'
  List of values: NumLevels ∈ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) .............................. angle.rad ∼ real
  Smallest rotation of the model.

  Default value: -0.39
  Suggested values: AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]
\[ \text{AngleExtent} \] (input_control) \[ \text{Extent of the rotation angles.} \]

- Default value: 0.79
- Suggested values: \( \text{AngleExtent} \in \{6.28, 3.14, 1.57, 0.79, 0.39\} \)
- Restriction: \( \text{AngleExtent} \geq 0 \)

\[ \text{ScaleMin} \] (input_control) \[ \text{Minimum scale of the model.} \]

- Default value: 0.9
- Suggested values: \( \text{ScaleMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
- Restriction: \( \text{ScaleMin} > 0 \)

\[ \text{ScaleMax} \] (input_control) \[ \text{Maximum scale of the model.} \]

- Default value: 1.1
- Suggested values: \( \text{ScaleMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\} \)
- Restriction: \( \text{ScaleMax} \geq \text{ScaleMin} \)

\[ \text{Optimization} \] (input_control) \[ \text{Kind of optimization.} \]

- Default value: 'auto'
- List of values: \( \text{Optimization} \in \{\text{’auto’, ’none’, ’point_reduction_low’, ’point_reduction_medium’, ’point_reduction_high’}\} \)

\[ \text{Metric} \] (input_control) \[ \text{Match metric.} \]

- Default value: 'use_polarity'
- List of values: \( \text{Metric} \in \{\text{’use_polarity’, ’ignore_global_polarity’, ’ignore_local_polarity’, ’ignore_color_polarity’}\} \)

\[ \text{Contrast} \] (input_control) \[ \text{Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.} \]

- Default value: 'auto'
- Suggested values: \( \text{Contrast} \in \{\text{’auto’, ’auto_contrast’, ’auto_contrast_hyst’, ’auto_min_size’, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}\} \)

\[ \text{MinContrast} \] (input_control) \[ \text{Minimum contrast of the objects in the search images.} \]

- Default value: 'auto'
- Suggested values: \( \text{MinContrast} \in \{\text{’auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40}\} \)
- Restriction: \( \text{MinContrast} < \text{Contrast} \)

\[ \text{GenParamName} \] (input_control) \[ \text{The general parameter names.} \]

- Default value: []
- List of values: \( \text{GenParamName} \in \{\text{’cam_param’}\} \)

\[ \text{GenParamValue} \] (input_control) \[ \text{Values of the general parameter.} \]

- Default value: []
- List of values: \( \text{GenParamValue} \in \{\}\)

### find_local_deformable_model

```plaintext
find_local_deformable_model { Image : ImageRectified, VectorField, DeformedContours : ModelID, AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, MinScore, NumMatches, MaxOverlap, NumLevels, Greediness, ResultType, GenParamName, GenParamValue : Score, Row, Column }
```

Find the best matches of a local deformable model in an image.

The operator `find_local_deformable_model` finds the best `NumMatches` instances of the locally deformable model `ModelID` in the input `Image`. The model must have been created previously by calling `create_local_deformable_model` or `read_deformable_model`.

The model is searched within those points of the domain of the image in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore`. Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with `set_system('border_shape_models','true')`, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels them model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., `dilation_circle`.

The operator `find_local_deformable_model` returns the `Row` and `Column` coordinates of the found instances. Additionally, a rectified part of the image, the respective vector field, and the contours of the found deformed model instance can be returned in `ImageRectified`, `VectorField`, and `DeformedContours`. By default, these iconic objects are not returned. In case that they are needed the parameter `ResultType` should be set to 'image_rectified', 'vector_field' and 'deformed_contours'. The size of `ImageRectified` and `VectorField` is the smallest axis-aligned rectangle of the domain of the image that was used to create the local deformable model with `create_local_deformable_model`. The size of the rectified image and the vector field can be expanded in all directions by setting `GenParamName` to 'expand_border' and the respective `GenParamValue` to the number of pixels. Optionally, a specific direction can be selected with 'expand_border_top', 'expand_border_bottom', 'expand_border_left', and 'expand_border_right'. Please note that the returned `VectorField` is in absolute coordinates and can be used for `convert_map_type`.

The smoothness of the estimated deformation can be selected with `GenParamName` set to 'deformation_smoothness'. The value for 'deformation_smoothness' can be imagined as the size of a smoothing filter to the estimated deformation field. A too small value expects a strong deformation a too big value expects a rigid object. The minimal value for 'deformation_smoothness' is 3, a typical value is 11, and the value can be increased further for only small global deformations.

Finally, the score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image.

HALCON 20.05.0.0
For further explanation on the parameters used for the search of a local deformable model we refer to the description of `find_planar_uncalib_deformable_model`.

18.3. DEFORMABLE

MaxOverlap (input_control) .......................................................... real  ⇆ real
Maximum overlap of the instances of the model to be found.

Default value: 1.0
Suggested values: MaxOverlap ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Typical range of values: 0 ≤ MaxOverlap ≤ 1
Minimum increment: 0.01
Recommended increment: 0.05

NumLevels (input_control) ............................................................ integer  ⇆ integer
Number of pyramid levels used in the matching.

Default value: 0
List of values: NumLevels ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

Greediness (input_control) ............................................................ real  ⇆ real
“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).

Default value: 0.9
Suggested values: Greediness ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Typical range of values: 0 ≤ Greediness ≤ 1
Minimum increment: 0.01
Recommended increment: 0.05

ResultType (input_control) ......................................................... string-array  ⇆ string
Switch for requested iconic result.

Default value: []
List of values: ResultType ∈ {[], ‘image_rectified’, ‘vector_field’, ‘deformed_contours’}

GenParamName (input_control) ...................................................... string-array  ⇆ string
The general parameter names.

Default value: []
List of values: GenParamName ∈ {[], ‘subpixel’, ‘angle_step’, ‘scale_r_step’, ‘scale_c_step’,
‘expand_border_left’, ‘expand_border_right’}

GenParamValue (input_control) ...................................................... integer-array  ⇆ integer / real / string
Values of the general parameters.

Default value: []
List of values: GenParamValue ∈ {[], ‘none’, ‘least_squares’, ‘least_squares_high’,
‘least_squares_very_high’}

Score (output_control) ............................................................... real-array  ⇆ real
Scores of the found instances of the model.

Row (output_control) ............................................................... real-array  ⇆ real
Row coordinates of the found instances of the model.

Column (output_control) ........................................................... real-array  ⇆ real
Column coordinates of the found instances of the model.

Result

If the parameters are valid, the operator find_local_deformable_model returns the value 2
(H_MSG_TRUE). If necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Matching

HALCON 20.05.0.0
**find_planar_calib_deformable_model** (Image : ModelID,
AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin,
ScaleCMax, MinScore, NumMatches, MaxOverlap, NumLevels,
Greediness, GenParamName, GenParamValue : Pose, CovPose, Score)

Find the best matches of a calibrated deformable model in an image and return their 3D pose.

The operator **find_planar_calib_deformable_model** finds the best NumMatches instances of the calibrated deformable model ModelID in the input image Image. The model must have been created previously by calling **create_planar_calib_deformable_model** or **read_deformable_model**. The operator **find_planar_calib_deformable_model** returns the 3D Pose of the found instances in the camera coordinate system.

Additionally, the accuracy of the six pose parameters are returned in CovPose. By default, CovPose contains the 6 standard deviations of the pose parameters for each match. If the generic parameter 'cov_pose_mode' was set to 'covariances', CovPose contains the 36 values of the complete \(6 \times 6\) covariance matrix of the 6 pose parameters. Note that this reflects only an inner accuracy from which the real accuracy of the pose may differ. Finally, the score of each found instance is returned in Score. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image.

For further explanation on the planar deformable model and its parameters we refer to the description of **find_planar_uncalib_deformable_model**.

---

**Parameters**

- **Image** (input_object) (multichannel-)image ~ object : byte / uint2
  Input image in which the model should be found.

- **ModelID** (input_control) deformable_model ~ handle
  Handle of the model.

- **AngleStart** (input_control) angle.rad ~ real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: AngleStart ∈ \{-3.14, -1.57, -0.78, -0.39, -0.20, 0.0\}

- **AngleExtent** (input_control) angle.rad ~ real
  Extent of the rotation angles.
  Default value: 0.78
  Suggested values: AngleExtent ∈ \{6.29, 3.14, 1.57, 0.78, 0.39, 0.0\}
  Restriction: AngleExtent ≥ 0

- **ScaleRMin** (input_control) number ~ real
  Minimum scale of the model in row direction.
  Default value: 1.0
  Suggested values: ScaleRMin ∈ \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Restriction: ScaleRMin > 0

- **ScaleRMax** (input_control) number ~ real
  Maximum scale of the model in row direction.
  Default value: 1.0
  Suggested values: ScaleRMax ∈ \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}
  Restriction: ScaleRMax ≥ ScaleRMin

- **ScaleCMin** (input_control) number ~ real
  Minimum scale of the model in column direction.
  Default value: 1.0
  Suggested values: ScaleCMin ∈ \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Restriction: ScaleCMin > 0

- **ScaleCMax** (input_control) number ~ real
  Maximum scale of the model in column direction.
  Default value: 1.0
  Suggested values: ScaleCMax ∈ \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}
  Restriction: ScaleCMax ≥ ScaleCMin
18.3. DEFORMABLE

- **MinScore** (input_control) ......................................................... real  \(\sim\) real
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: MinScore \(\in\) \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Typical range of values: 0 \(\leq\) MinScore \(\leq\) 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) ................................................ integer  \(\sim\) integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: NumMatches \(\in\) \{0, 1, 2, 3, 4, 5, 10, 20\}

- **MaxOverlap** (input_control) ................................................ real  \(\sim\) real
  Maximum overlap of the instances of the model to be found.
  Default value: 1.0
  Suggested values: MaxOverlap \(\in\) \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Typical range of values: 0 \(\leq\) MaxOverlap \(\leq\) 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumLevels** (input_control) ................................................. integer(-array)  \(\sim\) integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).
  Default value: 0
  List of values: NumLevels \(\in\) \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

- **Greediness** (input_control) ................................................ real  \(\sim\) real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: Greediness \(\in\) \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Typical range of values: 0 \(\leq\) Greediness \(\leq\) 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **GenParamName** (input_control) ......................................... string-array  \(\sim\) string
  The general parameter names.
  Default value: []
  List of values: GenParamName \(\in\) \{[], 'subpixel', 'angle_change_restriction', 'aniso_scale_change_restriction', 'angle_step', 'scale_r_step', 'scale_c_step', 'cov_pose_mode'\}

- **GenParamValue** (input_control) ........................................ integer-array  \(\sim\) integer / real / string
  Values of the general parameters.
  Default value: []
  List of values: GenParamValue \(\in\) \{[], 'least_squares', 'least_squares_high', 'least_squares_very_high', 'standard_deviations', 'covariances'\}

- **Pose** (output_control) ...................................................... pose(-array)  \(\sim\) real / integer
  Pose of the object.

- **CovPose** (output_control) ................................................ real-array  \(\sim\) real
  6 standard deviations or 36 covariances of the pose parameters.

- **Score** (output_control) ..................................................... real-array  \(\sim\) real
  Score of the found instances of the model.

---

**Result**

If the parameters are valid, the operator `find_planar_calib_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Possible Predecessors**

`create_planar_calib_deformable_model`, `read_deformable_model`

HALCON 20.05.0.0
The operator \texttt{find_planar_uncalib_deformable_model} finds the best \texttt{NumMatches} instances of the perspectively distorted deformable model \texttt{ModelID} in the input image \texttt{Image}. The model must have been created previously by calling \texttt{create_planar_uncalib_deformable_model} or \texttt{read_deformable_model}.

\textbf{Input parameters in detail}

\textbf{The image and its domain:} The domain of the image \texttt{Image} determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the deformable model with \texttt{create_planar_uncalib_deformable_model}. A different origin set with \texttt{set_deformable_model_origin} is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than \texttt{MinScore} (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\texttt{NumLevels}-1}$. This behavior can be changed with \texttt{set_system('border_shape_models','true')}, which will cause models that extend beyond the image border to be found if they achieve a score greater than \texttt{MinScore}. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\texttt{NumLevels}-1}$ using, e.g., \texttt{dilation_circle}.

\textbf{Angle and Scale parameters:} The parameters \texttt{AngleStart}, \texttt{AngleExtent}, \texttt{ScaleRMin}, \texttt{ScaleRMax}, \texttt{ScaleCMin}, and \texttt{ScaleCMax} are used to specify a basic range of up to an anisotropic transformation that is exhaustively searched on the top level of the image pyramid. The parameters \texttt{AngleStart} and \texttt{AngleExtent} determine the range of possible rotations in which the model is exhaustively searched. \texttt{ScaleRMin}, \texttt{ScaleRMax}, \texttt{ScaleCMin}, and \texttt{ScaleCMax} determine the range of possible anisotropic scales that are exhaustively searched in the image. A scale of 1 in both scale factors corresponds to the original size of the model.

The operator \texttt{find_planar_uncalib_deformable_model} may find objects outside this range, e.g., when the object is perspective distorted. Hence, the range parameters are a kind of suggestion for the search algorithm. Starting from this, certain models in a wider range of transformations can be detected, depending on the used pyramid levels, but also on the model/image content. It is important to note that, e.g., small scale changes can be tolerated without the need to specify a scale range, leading to faster execution times.

Often, it is not necessary to use an anisotropic scaling to find the object on the top level of the pyramid. In these cases, \texttt{ScaleCMin} and \texttt{ScaleCMax} should be set to 1. The search is then performed with isotropic scaling only, which is much faster. If the object should be detected despite severe perspective distortions anisotropic scaling is required. Here, \texttt{ScaleRMin} and \texttt{ScaleRMax} specify the anisotropic scaling in row, \texttt{ScaleCMin} and \texttt{ScaleCMax} in column direction.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Additionally, the operator \texttt{find_planar_uncalib_deformable_model} processes the parameters 'angle_step', 'scale_r_step' and 'scale_c_step' which can be set with the operator \texttt{create_planar_uncalib_deformable_model} or, as described below, with the generic parameters \texttt{GenParamName} and \texttt{GenParamValue}. In most cases, the values that can be determined automatically by \texttt{create_planar_uncalib_deformable_model} lead to good results.

The parameter 'angle_step' determines the step size within the selected range of angles. 'angle_step' should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in
the image, and hence 'angle_step' should be chosen larger for smaller models. If AngleExtent is not
an integer multiple of 'angle_step', 'angle_step' is modified accordingly. The parameters 'scale_r_step' and
'scale_c_step' determine the step size within the selected range of scales. Like 'angle_step', 'scale_r_step'
and 'scale_c_step' should be chosen based on the size of the object. If the respective range of scales is
not an integer multiple of 'scale_r_step' and 'scale_c_step', 'scale_r_step' and 'scale_c_step' are modified
accordingly.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded
as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the
model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more
than NumMatches instances with a score greater than MinScore are found in the image, only the best
NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned,
i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding
MinScore in the image should be found, NumMatches must be set to 0. In rare cases, NumMatches
must be set to a higher value than the required number of matches. This is the case if, for instance, a small
MinScore is set.

When tracking the matches through the image pyramid, on each level, some less promising matches are
rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a
higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to
1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.
If multiple objects with a similar score are expected, but only the one with the highest score should be
returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but
different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a
number between 0 and 1) two instances may at most overlap in order to consider them as different instances,
and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only
the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle
of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found
instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

GenParamName, GenParamValue: With the generic parameters GenParamName and GenParamValue it is
possible to adjust parameters that typically do not have to be set by the user. By default the pose is extracted
with high subpixel accuracy ('least_squares_very_high') through a least-squares adjustment, i.e., by mini-
mizing the distances of the model points to their corresponding image points. However, if no high accuracy
is required by an application, the subpixel precise extraction can be reduced or switched off as it increases
the processing time. Here, 'subpixel' must be passed in GenParamName and 'none', 'least_squares',
'least_squares_high' for GenParamValue. A further use of GenParamName and GenParamValue is
to override the discretization steps of the search space 'angle_step', 'scale_r_step' and 'scale_c_step' that
have been defined when the model was created in create_planar_uncalib_deformable_model. As
described in create_planar_uncalib_deformable_model the deformable matching algorithm
searches exhaustively a basic set of parameters that are specified with AngleStart,AngleExtent,
ScaleRMin,ScaleRMax,ScaleCMin and ScaleCMax. However, to allow a detection even when the
object is imaged under perspective distortion, an additional transformation is estimated. This additional
transformation transforms the model from the original search range to a bigger perspective distorted one. By
allowing perspective distortions, the risk of false positives is also increased. One possible use of the parameter
GenParamName is to help discarding false positives that occur, if for instance a small score was specified in
MinScore and the image contains significant clutter with similar shape as the model.
To restrict arbitrary perspective matches from occurring, the values 'angle_change_restriction' and
'aniso_scale_change_restriction' can be used in GenParamName. With 'angle_change_restriction' the
maximal tolerated angular distortion can be restricted. As default value $\frac{\pi}{2}$ is set, which allows arbitrary
distortion. By setting 'angle_change_restriction' to 0, no distortion is allowed at all. The set value should be
within the interval $[0, \frac{\pi}{2}]$. This parameter tests, if the angle of 90 degree at the corners of the axis-aligned
rectangle around the model points is changed by more than the corresponding GenParamValue for the
found instance of the model. Note that this parameter helps to restrict both affine (a shear mapping) and
perspective parts of the transformation. As an example, with 'angle_change_restriction' a square-like model
can be prevented to match with a parallelogram or an arbitrary trapezium.

With the parameter 'aniso_scale_change_restriction' the ratio of anisotropic scaling can be restricted (the
smaller scale factor divided by the bigger scale factor). The value of this parameter ranges from the default

HALCON 20.05.0.0
value 0.0, where arbitrary distortion is allowed, to 1.0, where no distortion is allowed. One typical use for this parameter is to restrict for instance a square-like model to deform to a rectangular model.

**NumLevels:** The number of pyramid levels used during the search is determined with **NumLevels**. If necessary, the number of levels is clipped to the range given when the deformable model was created with `create_planar_uncalib_deformable_model`. If **NumLevels** is set to 0, the number of pyramid levels specified in `create_planar_uncalib_deformable_model` is used.

**Greediness:** The parameter **Greediness** determines how “greedily” the search should be carried out. If **Greediness** = 0, a safe search heuristic is used, which finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If **Greediness** = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For **Greediness** = 1, the maximum search speed is achieved. In almost all cases, the deformable model will be found for **Greediness** = 0.9.

**Output parameters in detail**

**HomMat2D:** The projective transformation (homographies) that encode the position of the found instances of the model are returned in **HomMat2D**. In case that multiple objects are found, the different homographies are concatenated. A single homography can easily be extracted by `tuple_select_range(HomMat2D,Index*9,(Index+1)*9-1, SelectedHomMat2D)`. The different detection results are sorted in decreasing order of **Score**. The row and column coordinates are the coordinates of the origin of the deformable model in the search image, which can be found by calling `projective_trans_pixel(HomMat2D,0,0,Row,Column)`.

**Score:** Additionally, the score of each found instance is returned in **Score**. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

---

**Parameters**

- **Image** *(input_object)* (multichannel-)image  \(\sim object: \) byte / uint2
  Input image in which the model should be found.

- **ModelID** *(input_control)* deformable_model  \(\sim handle\)
  Handle of the model.

- **AngleStart** *(input_control)* angle.rad  \(\sim real\)
  Smallest rotation of the model.

  **Default value:** -0.39

  **Suggested values:** AngleStart \(\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)

- **AngleExtent** *(input_control)* angle.rad  \(\sim real\)
  Extent of the rotation angles.

  **Default value:** 0.78

  **Suggested values:** AngleExtent \(\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)

  **Restriction:** AngleExtent \(\geq 0\)

- **ScaleRMin** *(input_control)* number  \(\sim real\)
  Minimum scale of the model in row direction.

  **Default value:** 1.0

  **Suggested values:** ScaleRMin \(\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)

  **Restriction:** ScaleRMin \(> 0\)

- **ScaleRMax** *(input_control)* number  \(\sim real\)
  Maximum scale of the model in row direction.

  **Default value:** 1.0

  **Suggested values:** ScaleRMax \(\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)

  **Restriction:** ScaleRMax \(\geq \text{ScaleRMin} \)
18.3. DEFORMABLE

- **ScaleCMin** (input_control) .......................... number $\rightarrow$ real
  Minimum scale of the model in column direction.
  Default value: 1.0
  Suggested values: $\text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Restriction: $\text{ScaleCMin} > 0$

- **ScaleCMax** (input_control) .......................... number $\rightarrow$ real
  Maximum scale of the model in column direction.
  Default value: 1.0
  Suggested values: $\text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
  Restriction: $\text{ScaleCMax} \geq \text{ScaleCMin}$

- **MinScore** (input_control) .......................... real $\rightarrow$ real
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: $\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{MinScore} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) .......................... integer $\rightarrow$ integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: $\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}$

- **MaxOverlap** (input_control) .......................... real $\rightarrow$ real
  Maximum overlap of the instances of the model to be found.
  Default value: 1.0
  Suggested values: $\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{MaxOverlap} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumLevels** (input_control) .......................... integer(-array) $\rightarrow$ integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if $|\text{NumLevels}| = 2$).
  Default value: 0
  List of values: $\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- **Greediness** (input_control) .......................... real $\rightarrow$ real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: $\text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{Greediness} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **GenParamName** (input_control) .......................... string-array $\rightarrow$ string
  The general parameter names.
  Default value: []
  List of values: GenParamName $\in \{[], \text{`subpixel'}, \text{`angle_change_restriction',}
  \text{`aniso_scale_change_restriction', `angle_step', `scale_r_step', `scale_c_step'}\}$

- **GenParamValue** (input_control) .......................... integer-array $\rightarrow$ integer / real / string
  Values of the general parameters.
  Default value: []
  List of values: GenParamValue $\in \{[], \text{`none', `least_squares', `least_squares_high',}
  \text{`least_squares_very_high'}\}$

- **HomMat2D** (output_control) .......................... hom_mat2d(-array) $\rightarrow$ real
  Homographies between model and found instances.

- **Score** (output_control) .......................... real-array $\rightarrow$ real
  Score of the found instances of the model.

If the parameters are valid, the operator find_planar_uncalib_deformable_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

HALCON 20.05.0.0
Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Multithreading scope: global (may be called from any thread).

Automatically parallelized on internal data level.

Possible Predecessors
create_planar_uncalib_deformable_model, read_deformable_model

Alternatives
find_planar_calib_deformable_model

Module

get_deformable_model_contours ( : ModelContours : ModelID, Level : )

Return the contour representation of a deformable model.

The operator get_deformable_model_contours returns a representation of the deformable model ModelID as XLD contours in ModelContours. The parameter Level determines for which pyramid level of the model the contour representation should be returned. The contours can be used, for example, to visualize the found instances of the model in an image.

In case that the model was generated by create_planar_calib_deformable_model_xld, the contours by default are returned in the world coordinate system in metric units. Here, the contours must be transformed by the returned pose for visualizing a match.

In all other cases, the contours of the model by default are returned in the image coordinate system in pixel units. In the calibrated case this system corresponds to the rectified image coordinate system. The rectified image coordinate system is the coordinate system of an image one would obtain by change_radial_distortion_image when using the rectified camera parameters. The rectified camera parameters can be queried by get_deformable_model_params. It should be noted that the position of ModelContours is normalized such that the reference point of the model (see set_deformable_model_origin) lies at the pixel position (0, 0). Hence, the contours simply need to be transformed by the found homography in the image.

The default behavior for the calibrated case can be changed with the generic parameter 'get_deformable_model_contours_coord_system' of the operator set_deformable_model_param.

Parameters

- ModelContours (output_object) : xld_cont-array : xld_cont-arrayCONN
  Contour representation of the deformable model.
- ModelID (input_control) : deformable_model : handle
  Handle of the model.
- Level (input_control) : integer
  Pyramid level for which the contour representation should be returned.

Default value: 1
Suggested values: Level ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: Level >= 1

Result

If the handle of the model is valid, the operator get_deformable_model_contours returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
get_deformable_model_origin ( : : ModelID : Row, Column )

Return the origin (reference point) of a deformable model.

The operator `get_deformable_model_origin` returns the origin (reference point) of the deformable model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

### Parameters

- **ModelID** (input_control) .................................................., deformable_model  `~` handle
  Handle of the model.
- **Row** (output_control) .................................................., point.y  `~` real
  Row coordinate of the origin of the deformable model.
- **Column** (output_control) .............................................., point.x  `~` real
  Column coordinate of the origin of the deformable model.

### Result

If the handle of the model is valid, the operator `get_deformable_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

get_deformable_model_params ( : : ModelID,
    GenParamName : GenParamValue )

Return the parameters of a deformable model.
The operator `get_deformable_model_params` allows to query parameters of the deformable model. The names of the desired parameters are passed in the generic parameter `GenParamName`, the corresponding values are returned in `GenParamValue`.

The following parameters can be queried:

- `'cam_param'`: Internal parameters of the camera that is used for the calibrated case.
- `'cam_param_rect'`: Rectified internal parameters of the camera that is used for the calibrated case.
- `'reference_pose'`: Reference position and orientation of the calibrated deformable model. The returned pose describes the model plane that the user provided.
- `'model_pose'`: Reference position and orientation of the deformable model. The returned pose describes the pose of the internally used 3D metric model that was used for model generation.
- `'angle_start'`: The smallest rotation angle of the model.
- `'angle_extent'`: The extent of the rotation angle of the model.
- `'angle_step'`: The angle step length of the model.
- `'scale_r_min'`: The minimum scale of the pattern in row direction.
- `'scale_r_max'`: The maximum scale of the pattern in row direction.
- `'scale_r_step'`: The scale step of the pattern in row direction.
- `'scale_c_min'`: The minimum scale of the pattern in column direction.
- `'scale_c_max'`: The maximum scale of the pattern in column direction.
- `'scale_c_step'`: The scale step of the pattern in column direction.
- `'num_levels'`: User-specified number of pyramid levels.
- `'optimization'`: Kind of optimization by reducing the number of model points.
- `'min_size'`: Minimum size of the deformable model edge.
- `'min_contrast'`: Minimum contrast of the objects in the search images.
- `'metric'`: Match metric.
- `'model_row'`: Row coordinate of origin in the radial undistorted model image.
- `'model_col'`: Column coordinate of origin in the radial undistorted model image.
- `'model_type'`: The type of the model: 'planar_uncalib', 'planar_calib' or 'local'.
- `'created_from_xld'`: Was the model created from XLD or from an image: 'created_from_xld' or 'created_from_image'.
- `'get_deformable_model_contours_coord_system'`: Coordinate system ('image' or 'world') in which contours are returned when calling the operator `get_deformable_model_contours`.

A detailed description of the parameters can be looked up with the operator `create_planar_uncalib_deformable_model` and `create_planar_calib_deformable_model` or with the operator `get_deformable_model_contours`.

Note that although the parameter `Contrast` can be determined automatically during the model creation, its value cannot be queried using `get_deformable_model_params`. Instead, the operator `determine_deformable_model_params` should be used to retrieve its value.

It is possible to query the values of several parameters with a single operator call by passing a tuple containing the names of all desired parameters to `GenParamName`. As a result a tuple of the same length with the corresponding values is returned in `GenParamValue`. Note that this is solely possible for parameters that return only a single value.

---

**Parameters**

- `ModelID` (input_control) .......................... deformable_model ~> handle Handle of the model.
- `GenParamName` (input_control) .......................... attribute.name(-array) ~> string Names of the generic parameters that are to be queried for the deformable model.

**Default value:** 'angle_start'

**List of values:** `GenParamName` ∈ {'cam_param', 'cam_param_rect', 'angle_start', 'angle_extent', 'angle_step', 'scale_r_min', 'scale_r_max', 'scale_r_step', 'scale_c_min', 'scale_c_max', 'scale_c_step', 'optimization', 'metric', 'min_contrast', 'num_levels', 'min_size', 'reference_pose', 'model_pose', 'model_row', 'model_col', 'model_type', 'created_from_xld', 'get_deformable_model_contours_coord_system'}
18.3. DEFORMABLE

- **GenParamValue** (output_control) .................. attribute.name(-array) \(\sim\) string / integer / real
  Values of the generic parameters.

- **Result**
  If the parameters are valid, the operator `get_deformable_model_params` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

- **Parallelization**

**read_deformable_model** ( : : FileName : ModelID )

Read a deformable model from a file.

The operator `read_deformable_model` reads a deformable model from the file `FileName`, which has been written with `write_deformable_model`. The default HALCON file extension for the deformable model is ‘dfm’.

- **Parameters**
  • `FileName` (input_control) .................. filename.read \(\sim\) string
    File name.
    File extension: .dfm
  • `ModelID` (output_control) .................. deformable_model \(\sim\) handle
    Handle of the model.

- **Parallelization**
  • Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  • Multithreading scope: global (may be called from any thread).
  • Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

HALCON 20.05.0.0
### serialize_deformable_model ( : : ModelID : SerializedItemHandle )

**Serialize a deformable model.**

serialize_deformable_model serializes the data of a deformable model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_deformable_model is converted to a serialized item. The deformable model is defined by the handle ModelID. The serialized deformable model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_deformable_model.

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelID</td>
<td>(input_control) Handle of a model to be saved.</td>
</tr>
<tr>
<td>SerializedItemHandle</td>
<td>(output_control) Handle of the serialized item.</td>
</tr>
</tbody>
</table>

#### Result

If the parameters are valid, the operator serialize_deformable_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

#### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

#### Possible Predecessors

create_planar_uncalib_deformable_model, create_planar_calib_deformable_model, create_local_deformable_model

#### Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_deformable_model

### set_deformable_model_origin ( : : ModelID, Row, Column : )

**Set the origin (reference point) of a deformable model.**

The operator set_deformable_model_origin sets the origin (reference point) of the deformable model ModelID to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the deformable model with create_planar_uncalib_deformable_model. Hence, an origin of (0,0) means that the center of gravity of the domain of the deformable image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity. If a deformable model was created by create_planar_calib_deformable_model the 3D pose of the origin changes by the respective translation. Hence, further calls of find_planar_calib_deformable_model will include the pose offset. If a deformable model was created by create_planar_calib_deformable_model_xid the 3D pose of the origin changes directly by the offset. This means that the offsets are interpreted in world coordinates. In this case, the row coordinate corresponds to the y world coordinate (from top to down) and the column coordinate corresponds to the x world coordinate (from left to right).

#### Parameters

<table>

**Matching**

```plaintext
set_deformable_model_param ( : : ModelID, GenParamName, GenParamValue : )
```

Set selected parameters of the deformable model.

The operator `set_deformable_model_param` sets the selected parameters `GenParamName` in the deformable model `ModelID`. The following parameters can be modified:

- **'min_contrast'**
  
  Sets the minimum contrast of the object in the search images for the deformable model `ModelID`. Thereby, the value of 'min_contrast' that was originally set, e.g., with `create_planar_uncalib_deformable_model`, is overwritten for the deformable model `ModelID`. Note that if the deformable model `ModelID` was read from file and if this file should be changed as well, the deformable model `ModelID` must again be written to file after the execution of the operator `set_deformable_model_param`.

- **'get_deformable_model_contours_coord_system'**
  
  Sets the coordinate system in which the contours are returned when calling the operator `get_deformable_model_contours`. If 'world' is passed, the contours are returned in the world coordinate system in metric units. Note that this is only possible for the calibrated case. If 'image' is passed, the contours are returned in the image coordinate system in pixel units. In the calibrated case this system corresponds to the rectified image coordinate system. The rectified image coordinate system is the coordinate system of an image one would obtain by `change_radial_distortion_image` when using the rectified camera parameters. The rectified camera parameters can be queried by `get_deformable_model_params`. If the model was created by `create_planar_calib_deformable_model_xld` the value of 'get_deformable_model_contours_coord_system' is 'world' by default. In all other cases it is 'image' by default.
### Parameters

- **ModelID** (input_control)  
  Handle of the model.

- **GenParamName** (input_control)  
  Parameter names.  
  **List of values:** GenParamName ϵ {'min_contrast', 'get_deformable_model_contours_coord_system'}

- **GenParamValue** (input_control)  
  Parameter values.  
  **Suggested values:** GenParamValue ϵ {5, 6, 7, 8, 9, 10, 'image', 'world'}

If the parameters are valid, the operator `set_deformable_model_param` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Result

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Matching

```c
set_local_deformable_model_metric ( Image,
    VectorField : : ModelID, Metric : )
```

Set the metric of a local deformable model that was created from XLD contours.

The operator `set_local_deformable_model_metric` changes the value of the parameter **Metric** that was selected during the creation of the deformable model **ModelID** from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative **Image**. For this, the model contours are mapped to the respective position where the object appears in the **Image**, which is done with the **VectorField** which must be of the semantic type ‘vector_field_absolute’ and which can be obtained by a previous call to `find_local_deformable_model`. Here, the returned **VectorField** is used for the deformable transformation. Note, that the ‘expand_border’ option should not be used in `find_local_deformable_model`, because then the returned **VectorField** has the wrong image size.

The parameter **Metric** then determines the conditions under which the model is recognized later in the search image. If **Metric** = ‘use_polarity’, the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If **Metric** = ‘ignore_global_polarity’, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_local_deformable_model` will increase slightly in this case.
It must be ensured that the object contours in the `Image` have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the `Image` and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in `Image`, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter `Metric` to 'ignore_local_polarity'. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image is provided in `VectorField`, which is of the semantic type 'vector_field_absolute'. If the matching result is correct, the value of the parameter `Metric` can be changed, e.g., to 'use_polarity'. This leads to a faster and more robust recognition in the following images.

Attention

set_local_deformable_model_metric can only be used with deformable models that were created from XLD contours.

Parameters

- `Image` (input_object) : singlechannelimage  \( \sim \) object : byte / uint2
  Input image used for the determination of the polarity.
- `VectorField` (input_object) : singlechannelimage  \( \sim \) object : vector_field
  Vector field of the local deformation.
- `ModelID` (input_control) : deformable_model  \( \sim \) handle
  Handle of the model.
- `Metric` (input_control) : string  \( \sim \) string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric \( \in \) {'use_polarity', 'ignore_global_polarity'}

Result

If the parameters are valid, the operator set_local_deformable_model_metric returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

set_planar_calib_deformable_model_metric ( Image : : ModelID, Pose, Metric : )

Set the metric of a planar calibrated deformable model that was created from XLD contours.
set_planar_calib_deformable_model_metric changes the value of the parameter Metric that was selected during the creation of the deformable model ModelID from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative Image. For this, the model contours are mapped to the respective position where the object appears in the Image using Pose, which can be obtained by a previous call to find_planar_calib_deformable_model.

The parameter Metric then determines the conditions under which the model is recognized later in the search image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_planar_calib_deformable_model will increase slightly in this case.

It must be ensured that the object contours in the Image have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the Image and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in Image, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter Metric to 'ignore_local_polarity'. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image Pose can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter Metric can be changed, e.g., to 'use_polarity'. This leads to a faster and more robust recognition in the following images.

Attention

set_planar_calib_deformable_model_metric can only be used with deformable models that were created from XLD contours.

Parameters

- **Image** (input_object) ........................................... singlechannelimage ~ object : byte / uint2
  Input image used for the determination of the polarity.
- **ModelID** (input_control) ........................................... deformable_model ~ handle
  Handle of the model.
- **Pose** (input_control) ............................................. pose ~ real / integer
  Pose of the model in the image.
  Number of elements: 7
- **Metric** (input_control) ......................................... string ~ string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric ∈ {'use_polarity', 'ignore_global_polarity'}

Result

If the parameters are valid, the operator set_planar_calib_deformable_model_metric returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

#### Module

**Matching**

### create_calib_descriptor_model ( Template : : CamParam,  
  ReferencePose, DetectorType, DetectorParamName, DetectorParamValue,  
  DescriptorParamName, DescriptorParamValue, Seed : ModelID )

Create a descriptor model for calibrated perspective matching.

The operator `create_calib_descriptor_model` prepares a descriptor model, which is used for calibrated descriptor-based matching, from a template image that is passed in `Template` (usually the domain of the image is reduced to an ROI showing only the object of interest). Note that the part of the object that is visible in the `Template` image needs to be planar.

The internal camera parameters `CamParam` and the `ReferencePose`, which describes the 3D position and orientation of the object plane shown in `Template`, are used to internally calculate a model coordinate system. The origin of this model coordinate system is obtained by projecting the center of gravity of an internally rectified version of the template image onto the object plane. The axes of the model coordinate system are built such that they are parallel to the axes of Reference Pose. To obtain a descriptor model from the template image, the points extracted by the detector in the internally rectified template image are projected onto the object plane as well. Their coordinates in the model coordinate system are stored as world coordinates in the model. This model then can be used for the pose estimation of a searched object as described with `find_calib_descriptor_model`.

A descriptor model created by the use of `create_calib_descriptor_model` can also be used in `find_uncalib_descriptor_model` to determine a homography. In contrast, it is not possible to use a model created by `create_uncalib_descriptor_model` in `find_calib_descriptor_model`.

The descriptor model describes a set of points of interest. It stores their locations and discriminative descriptions of their local gray value neighborhood. The interest point extraction is parametrized by `DetectorType`. 
DetectorParamName and DetectorParamValue. The respective descriptor around the interest points is
parametrized by DescriptorParamName and DescriptorParamValue. The parameter Seed seeds the
random number generator, which is used during the construction of the descriptor implemented with randomized
ferns. The returned ModelID is a reference to the generated descriptor model. For further explanation on the
descriptor model and its parameter we refer to the description of create_uncalib_descriptor_model.
The parameters and the location of the final descriptor points can be determined with
get_descriptor_model_params and get_descriptor_model_points.
create_calib_descriptor_model stores the detector type, detector parameters and descrip-
tor parameters, which are used in every succeeding call of find_calib_descriptor_model or
find_uncalib_descriptor_model. The reference point (origin) of the model is the center of gravity
of the template’s ROI. Its coordinates can be changed by set_descriptor_model_origin.

Parameters

- **Template** (input_object) ......................... singlechannelimage ~ object : byte / uint2
  Input image whose domain will be used to create the model.
- **CamParam** (input_control) ....................... campar ~ real / integer / string
  The parameters of the internal orientation of the camera.
- **ReferencePose** (input_control) .................. pose ~ real / integer
  The reference pose of the object in the reference image.
- **DetectorType** (input_control) ................... string ~ string
  The type of the detector.
  Default value: ‘lepetit’
  List of values: DetectorType ∈ [‘lepetit’, ‘harris’, ‘harris_binomial’]
- **DetectorParamName** (input_control) ............ attribute.name-array ~ string
  The detector’s parameter names.
  Default value: []
  List of values: DetectorParamName ∈ [’alpha’, ’check_neighbor’, ’mask_size_grd’, ’mask_size_smooth’, ”min_check_neighbor_diff”, ’min_score’, ’radius’, ’sigma_grad’, ’sigma_smooth’, ’subpix’, ’threshold’]
- **DetectorParamValue** (input_control) .......... attribute.value-array ~ integer / real / string
  Values of the detector’s parameters.
  Default value: []
  Suggested values: DetectorParamValue ∈ {0.08, 1, 1.2, 3, 15, 30, 1000, ’on’, ’off’}
- **DescriptorParamName** (input_control) ............ attribute.name-array ~ string
  The descriptor’s parameter names.
  Default value: []
  List of values: DescriptorParamName ∈ [’depth’, ’max_rot’, ’max_scale’, ’min_rot’, ’min_scale’, ’number_ferns’, ’patch_size’, ’tilt’]
- **DescriptorParamValue** (input_control) .......... attribute.value-array ~ integer / real / string
  Values of the descriptor’s parameters.
  Default value: []
  Suggested values: DescriptorParamValue ∈ {0.5, 1.4, 11, 21, 30, -180, 180, ’on’, ’off’}
- **Seed** (input_control) ............................ integer ~ integer
  The seed for the random number generator.
  Default value: 42
- **ModelID** (output_control) ........................ descriptor_model ~ handle
  The handle to the descriptor model.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific
operators even though the handle is used as an input parameter by those operators.

Matching

create_uncalib_descriptor_model ( Template : : DetectorType,
DetectorParamName, DetectorParamValue, DescriptorParamName,
DescriptorParamValue, Seed : ModelID )

Prepare a descriptor model for interest point matching.

The operator create_uncalib_descriptor_model prepares a descriptor model of an image region, which is passed in the image Template, that can be used for descriptor-based matching. By a subsequent call of find_uncalib_descriptor_model a projective 2D transformation (homography) from Template to a search image can be obtained. The center of gravity of the domain region in Template is used as an origin of the model. In contrast to create_calib_descriptor_model, no calibrated camera is needed and hence the result of a subsequent matching is a 2D projection. Note that the part of the object that is visible in the Template image needs to be planar.

The descriptor model describes a set of points of interest. It stores their locations and discriminative descriptions of their local gray value neighborhood. The interest point extraction is parametrized by DetectorType, DetectorParamName and DetectorParamValue. The respective descriptor around the interest points is parametrized by DescriptorParamName and DescriptorParamValue. The parameter Seed seeds the random number generator, which is used during the construction of the descriptor implemented with randomized ferns. The returned ModelID is a reference to the generated descriptor model. This model can be used for an efficient detection of instances of the learned template with find_uncalib_descriptor_model, allowing perspective transformation between model and search image. As descriptor-based matching relies on the existence of stable and discriminative points of interest, the object to be detected must be textured, but not in a repetitive way.

Detector parameters

As mentioned, the detector is used for the extraction of stable interest points within the image. By the parameter DetectorType, it is possible to select the interest point operator to be used. Currently, points_lepetit, points_harris, and its binomial approximation points_harris_binomial are supported (‘lepetit’, ‘harris’, ‘harris_binomial’). In case of templates or search images with a low contrast, one of the harris point operators should be used. Depending on the selected DetectorType, appropriate parameter names and values can be set in DetectorParamName and DetectorParamValue.

Possible parameter names for DetectorParamName and corresponding default values are:

'lepetit': ['radius', 'check_neighbor', 'min_check_neighbor_diff', 'min_score', 'subpix']
[3, 1, 15, 30, 'interpolation']
'harris': ['sigma_grad', 'sigma_smooth', 'alpha', 'threshold']
[0.7, 2.0, 0.08, 1000]
'harris_binomial': ['mask_size_grd', 'mask_size_smooth', 'alpha', 'threshold', 'subpix']
[5, 15, 0.08, 1000, 'on']
Further details on the meaning of those parameters can be found in the descriptions of `points_harris`, `points_harris_binomial` and `points_lepetit`, respectively. If an empty tuple is passed or a parameter is not provided in `DetectorParamName`, the above-mentioned default values are taken.

While adjusting the operator parameters it should be aimed that a set of 50 to 450 feature points is extracted (depending on the texture and size of `Template`), which are uniformly distributed over the template’s ROI. Therefore, it is recommended to run the point operator of choice in advance and visualize the results by `gen_cross_contour_xld`. In most cases it is sufficient to use the default setting.

**Descriptor parameters**

A point descriptor is a classifier, which builds characteristic descriptions of the gray-value neighborhood for interest points. Currently the descriptor is implemented with the so-called randomized ferns, which learns the polarity of the gray-value differences of pairs of pixels certain at random locations in the surrounding area of the interest point. The descriptor is later used in `find_uncalib_descriptor_model` to classify interest points in the search image, or in other words: to identify (match) potential model points in the search image.

The descriptor needs to store only the projectively stable interest points (which will appear in many projective views of the template). To assess the stability of the interest points, a simulation is performed: `Template` undergoes many affine transformations and points that can be extracted in most of the views are considered stable. The affine transformations are a good approximation of the projective transformations within a local neighborhood of the interest points.

The following descriptor parameters can be set with `DescriptorParamName` and `DescriptorParamValue`:

**Descriptor size parameters:**

`'depth'`: depth of a classification fern. A deeper randomized fern can better discriminate interest points. However, the memory requirement for the fern grows by a factor 2 to the power of `depth`. Typical values are `5 . . . 11`, default value is `11`.

`'number_ferns'`: number of fern structures used. Using more ferns increases the recognition robustness, however it also increases the runtime of the matching. If the memory needed for the descriptor should be small, many ferns with only a small depth should be used (e.g., `number_ferns`=150, `depth`=5). If detection speed is more important, fewer ferns of larger depth should be used (e.g., `number_ferns`=10, `depth`=11). Typical values are `1 . . . 150`, default value is 30.

`'patch_size'`: side length of a quadratic neighborhood describing a point of interest. Too large values of this parameter can influence the run time. Typical values are `15 . . . 33`, default value is 17.

Summing up, the parameters `depth`, `number_ferns` and `patch_size` allow a transparent control over detection robustness, speed and memory consumption.

**Simulation parameters:**

`'tilt'`: switches on or off the projective transformations during the simulation phase. When switched on, the robustness of the model is improved and objects with bigger tilts can be found. When switched off, training time can be significantly reduced and the model is still able to recognize projectively invariant objects.

Possible values are `[on`, `off`], default value is `on`.

`'min_rot'`: minimal angle of rotation around the normal vector of `Template`. Typical values are `[-180 . . . 0]`, default value is `-180`.

`'max_rot'`: maximal angle of rotation around the normal vector of `Template`. Typical values are `[0 . . . 180]`, default value is `180`.

`'min_scale'`: minimal scale of `Template`. Typical values are `[0.1 . . . 1.0]`, default value is `0.5`.

`'max_scale'`: maximal scale of `Template`. Typical values are `[1.0 . . . 3.5]`, default value is `1.4`.

The parameters `min_rot`, `max_rot`, `min_scale`, and `max_scale` allow to manually set which affine transformed views of the template are used to train the descriptor. Setting these parameters is useful to reduce training time especially in combination with the parameter `tilt`. Be aware that these parameters have direct influence on the results of `find_uncalib_descriptor_model` and therefore have to be set carefully. If, for example, the range of rotation is restricted from `min_rot` = -10 to `max_rot` = 10 it is not possible to find views of `Template` rotated...
by an angle outside that scope. A limited training range requires less ferns / ferns’ depths to find Template. In such a case the number and depth of the ferns can be further reduced, which optimizes the model.

**Remarks**

Please note that depending on your hardware, the processing time for training the randomized ferns can vary between several seconds to some minutes. Therefore, a once trained model can be saved and loaded with write_descriptor_model and read_descriptor_model.

The parameters and the location of the final descriptor points can be determined with get_descriptor_model_params and get_descriptor_model_points.

create_uncalib_descriptor_model stores the detector type, detector parameters, and descriptor parameters, which are used in every succeeding call of find_uncalib_descriptor_model. The reference point (origin) of the model is the center of gravity of the template’s ROI. Its coordinates can be changed by set_descriptor_model_origin.

### Parameters

- **Template** (input_object) singlechannelimage  \(\sim\) object : byte / uint2
  Input image whose domain will be used to create the model.

- **DetectorType** (input_control) string  \(\sim\) string
  The type of the detector.
  Default value: ‘lepetit’

- **DetectorParamName** (input_control) attribute.name-array string  \(\sim\) string
  The detector’s parameter names.
  Default value: []

- **DetectorParamValue** (input_control) attribute.value-array integer / real / string
  Values of the detector’s parameters.
  Default value: []

- **DescriptorParamName** (input_control) attribute.name-array string  \(\sim\) string
  The descriptor’s parameter names.
  Default value: []

- **DescriptorParamValue** (input_control) attribute.value-array integer / real / string
  Values of the descriptor’s parameters.
  Default value: []

- **Seed** (input_control) integer  \(\sim\) integer
  The seed for the random number generator.
  Default value: 42

- **ModelID** (output_control) descriptor_model  \(\sim\) handle
  The handle to the descriptor model.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

References

Module

deserialize_descriptor_model ( : : SerializedItemHandle : ModelID )

Deserialize a descriptor model.

deserialize_descriptor_model deserializes a descriptor model, that was serialized by serialize_descriptor_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized descriptor model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created descriptor model with the handle ModelID.

Parameters

> SerializedItemHandle (input_control) ....................... serialized_item ~> handle
Handle of the serialized item.

> ModelID (output_control) ................................. descriptor_model ~> handle
Handle of the model.

Result
If the parameters are valid, the operator deserialize_descriptor_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

find_calib_descriptor_model ( Image : : ModelID,
DetectorParamName, DetectorParamValue, DescriptorParamName,
DescriptorParamValue, MinScore, NumMatches, CamParam,
ScoreType : Pose, Score )

Find the best matches of a calibrated descriptor model in an image and return their 3D pose.
The operator `find_calib_descriptor_model` finds the best `NumMatches` matches of the descriptor model `ModelID` in `Image`. The descriptor model must have been created previously by calling `create_calib_descriptor_model` or `read_descriptor_model`.

The operator returns the 3D `Pose` (in camera coordinate system) of the template object found in the search `Image`. As two different cameras can be used for the model generation and the online search, the camera parameters of the camera used to create `Image` have to be set in `CamParam`.

The detection process is the same as for `find_uncalib_descriptor_model`. The setting of `DetectorParamName`, `DetectorParamValue`, `DescriptorParamName`, `DescriptorParamValue`, `MinScore`, `NumMatches` and `ScoreType` are explained with `find_uncalib_descriptor_model`. After the object was detected, and using the world (from reference plane) coordinates of the matched model points (explained with `create_calib_descriptor_model`), the pose of the object is computed similarly to applying the `vector_to_pose` operator.

The point correspondences for each object can be queried with `get_descriptor_model_points`.

**Attention**

Note that the domain of the search image should contain the whole object to be searched for because interest points are only extracted inside the domain of the search image. This means that if the domain does not contain the full object to be searched for, the resulting `Score` will decrease. Note also that matches may be found even if the reference point (origin) of the model lies outside of the domain of the search image. Both is in contrast to shape-based matching, where the domain of the search image defines the search space for the reference point of the model.

**Parameters**

- **Image** (input_object) singlechannelimage -> object : byte / uint2
  Input image where the model should be found.

- **ModelID** (input_control) descriptor_model -> handle
  The handle to the descriptor model.

- **DetectorParamName** (input_control) attribute.name-array -> string
  The detector’s parameter names.
  Default value: []
  List of values: `DetectorParamName` ∈ {'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold'}

- **DetectorParamValue** (input_control) attribute.value-array -> integer / real / string
  Values of the detector’s parameters.
  Default value: []
  Suggested values: `DetectorParamValue` ∈ {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off'}

- **DescriptorParamName** (input_control) attribute.name-array -> string
  The descriptor’s parameter names.
  Default value: []
  List of values: `DescriptorParamName` ∈ {'min_score_descr', 'guided_matching'}

- **DescriptorParamValue** (input_control) attribute.value-array -> real / integer / string
  Values of the descriptor’s parameters.
  Default value: []
  Suggested values: `DescriptorParamValue` ∈ {0.0, 0.001, 0.005, 0.01, 'on', 'off'}

- **MinScore** (input_control) real(-array) -> real
  Minimum score of the instances of the models to be found.
  Default value: 0.2
  Suggested values: `MinScore` ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: $0 \leq \text{MinScore} \leq 1$

- **NumMatches** (input_control) integer -> integer
  Maximal number of found instances.
  Default value: 1
  Suggested values: `NumMatches` ∈ {1, 2, 3, 4}
  Restriction: `NumMatches` $\geq$ 1

- **CamParam** (input_control) campar -> real / integer / string
  Camera parameter (inner orientation) obtained from camera calibration.
CHAPTER 18 MATCHING

- **ScoreType** (input_control) .......................................................... string(-array) ~ string
  Score type to be evaluated in Score.
  Default value: ‘num_points’
  List of values: ScoreType ∈ [‘num_points’, ‘inlier_ratio’]

- **Pose** (output_control) .......................................................... pose(-array) ~ real / integer
  3D pose of the object.

- **Score** (output_control) .......................................................... number(-array) ~ real / integer
  Score of the found instances according to the ScoreType input.

* Perform camera calibration (with standard calibration plate)
  calibrate_cameras (CalibDataID, Error)

**Module**
Matching

**find_uncalib_descriptor_model** ( Image : : ModelID, DetectorParamName, DetectorParamValue, DescriptorParamName, DescriptorParamValue, MinScore, NumMatches, ScoreType : HomMat2D, Score )

Find the best matches of a descriptor model in an image.
The operator find_uncalib_descriptor_model finds the best matches of a descriptor model ModelID in Image. The descriptor model must have been created previously by
calling  `create_uncalib_descriptor_model`,  `create_calib_descriptor_model`  or  `read_descriptor_model`.

A match is only accepted if its score exceeds the value of `MinScore`. This criterion is based on the ‘inlier_ratio’ score that is described in details below. The main result of the operator `find_uncalib_descriptor_model` for each match is a 3x3 matrix `HomMat2D`, which describes a 2D projection of model points to search image points and is represented by a tuple of 9 elements in row-major order. If more matches of the searched object (template) appear and pass the `MinScore` criterion, the resulting multiple homographies are concatenated. The number of objects actually found is then equal to `NumObjects = |HomMat2D|/9`.

The detection process is divided into three parts. **First**, interest points are extracted from the search image (only inside the domain of the search image). This is done using the point detector and its parameters selected once during the generation of the model. However, `DetectorParamName` and `DetectorParamValue` can be used to specify different detector parameter values during the `find_uncalib_descriptor_model` call. By changing these parameters, it is possible to adjust to illumination changes between the model generation and the online detection. However, it is recommended to use the same values used to create the model (pass an empty tuple).

**The second step** of the detection process is to calculate correspondences between the model points and the points that were detected. The run time parameters of the descriptor can be adjusted with `DescriptorParamName` and `DescriptorParamValue`:

- **'min_score_descr'**: is the minimal classifier score for an interest point to be regarded as a potential match. The score function is between 0.0 and 1.0, but typically only values between 0.0 and 0.1 make sense. Increasing ‘`min_score_descr’ might have negative effect on the robustness of the detection process, especially when only few points can be found.
  
  Typical values are [0.0 . . 0.1], default value is 0.0.

- **'guided_matching'**: enhances the accuracy of the object recognition when switched on. Note that it increases the computational costs up to 10% in some cases.
  
  Possible values are ['on', 'off'], default value is 'on'.

**The last step** is the estimation of a homography that describes the point correspondences. The homography is a 2D projection, which describes a transformation from model points to points in `Image`. Here, Natural 3D Markers (N3Ms) are utilized to identify robustly the point correspondences (see references).

Additionally to the estimated homography in `HomMat2D`, the operator returns one or more `Score` estimations per object instance as specified by the user in a tuple `ScoreType`. Currently the following values for `ScoreType` are supported:

- **'num_points'**: number of point correspondences per instance. An object instance should be considered good, if it has 10 or more point correspondences with the model. Fewer points are insufficient, because any random 4 point correspondences define a mathematically correct homography between two images.

- **'inlier_ratio'**: the ratio of the number of point correspondences to the number of model points. Although this value can have values of [0.0 . . 1.0], it is rather unlikely that this ratio can reach 1.0. Yet, objects having inlier ratio less than 0.1, should be disregarded.

Note that the resulting scores for more than one object instance will be concatenated in `Score`, such that `|Score| = NumObjects*|ScoreType|`.

The point correspondences for each object can be queried with `get_descriptor_model_points`.

---

**Attention**

Note that the domain of the search image should contain the whole object to be searched for because interest points are only extracted inside the domain of the search image. This means that if the domain does not contain the full object to be searched for, the resulting `Score` will decrease. Note also that matches may be found even if the reference point (origin) of the model lies outside of the domain of the search image. Both is in contrast to shape-based matching, where the domain of the search image defines the search space for the reference point of the model.
Parameters

- **Image** (input_object) .............................................................. singlechannelimage ~ object : byte / uint2
  Input image where the model should be found.

- **ModelID** (input_control) ......................................................... descriptor_model ~ handle
  The handle to the descriptor model.

- **DetectorParamName** (input_control) ......................................... attribute.name-array ~ string
  The detector’s parameter names.
  Default value: []
  List of values: DetectorParamName ∈ ['alpha', 'check_neighbor', 'mask_size_grd',
  'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth',
  'subpix', 'threshold']

- **DetectorParamValue** (input_control) ........................................ attribute.value-array ~ integer / real / string
  Values of the detector’s parameters.
  Default value: []
  Suggested values: DetectorParamValue ∈ {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off'}

- **DescriptorParamName** (input_control) ....................................... attribute.name-array ~ string
  The descriptor’s parameter names.
  Default value: []
  List of values: DescriptorParamName ∈ ['min_score_descr', 'guided_matching']

- **DescriptorParamValue** (input_control) ..................................... attribute.value-array ~ real / integer / string
  Values of the descriptor’s parameters.
  Default value: []
  Suggested values: DescriptorParamValue ∈ {0.0, 0.001, 0.005, 0.01, 'on', 'off'}

- **MinScore** (input_control) ..................................................... real(-array) ~ real
  Minimum score of the instances of the models to be found.
  Default value: 0.2
  Suggested values: MinScore ∈ [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Typical range of values: 0 ≤ MinScore ≤ 1

- **NumMatches** (input_control) ................................................... integer ~ integer
  Maximal number of found instances.
  Default value: 1
  Suggested values: NumMatches ∈ {1, 2, 3, 4}
  Restriction: NumMatches ≥ 1

- **ScoreType** (input_control) .................................................... string(-array) ~ string
  Score type to be evaluated in Score.
  Default value: 'num_points'
  List of values: ScoreType ∈ ['num_points', 'inlier_ratio']

- **HomMat2D** (output_control) ................................................... hom_mat2d(-array) ~ real
  Homography between model and found instance.

- **Score** (output_control) ...................................................... number(-array) ~ real / integer
  Score of the found instances according to the ScoreType input.

---

Example

```plaintext
create_uncalib_descriptor_model (ImageReduced,'harris',[],[],
    [],[],42,ModelID)
get_descriptor_model_params (ModelID,DetectorType,
    DetectorParamName,DetectorParamValue,
    DescriptorParamName,DescriptorParamValue)
write_descriptor_model (ModelID,'simple_example.dsm')
read_descriptor_model ('simple_example.dsm',ModelID)
find_uncalib_descriptor_model (SearchImage,ModelID,[],[],[],0.2,1,
    ['num_points','inlier_ratio'],HomMat2D,Score)

get_descriptor_model_origin ( : : ModelID : Row, Column )
Return the origin of a descriptor model.
The operator get_descriptor_model_origin returns the origin (reference point) of the descriptor
model ModelID. The origin is specified relative to the center of gravity of the domain (region) of the
image that was used to create the descriptor model with create_uncalib_descriptor_model, or
create_calib_descriptor_model. Hence, an origin of (0,0) means that the center of gravity of the
domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left
of the center of gravity.
Parameters
. ModelID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . .descriptor_model ; handle
Handle of a descriptor model.
. Row (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real ; real / integer
Position of origin in row direction.
. Column (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real ; real / integer
Position of origin in column direction.

get_descriptor_model_params ( : : ModelID : DetectorType,
DetectorParamName, DetectorParamValue,
DescriptorParamValue )

DescriptorParamName,

Return the parameters of a descriptor model.
HALCON 20.05.0.0


The operator `get_descriptor_model_params` allows to access the parameters of a descriptor model that was created with `create_uncalib_descriptor_model` or `create_calib_descriptor_model`. Therefore, a handle of a descriptor model must be passed in `ModelID`. The operator returns in `DetectorType`, `DetectorParamName` and `DetectorParamValue` the type and parameterization of the detector. In `DescriptorType`, `DescriptorParamName` and `DescriptorParamValue` the respective descriptor is returned.

An application for this operator is the possibility to query the parameters that were used in a stored model. As the operator needs a handle to a descriptor model, it has to be loaded first by using `read_descriptor_model`.

**Parameters**

- `ModelID` (input_control) .............................. `handle`
  The object handle to the descriptor model.
- `DetectorType` (output_control) ....................... `string`  
  The type of the detector.
- `DetectorParamName` (output_control) .................. `string`
  The detectors parameter names.
- `DetectorParamValue` (output_control) ............... `integer` / `real` / `string`
  Values of the detectors parameters.
- `DescriptorParamName` (output_control) ............... `string`
  The descriptors parameter names.
- `DescriptorParamValue` (output_control) ............... `integer` / `real` / `string`
  Values of the descriptors parameters.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

**Module**

**MatchModel**

---

**get_descriptor_model_points**

```plaintext```
( : : ModelID, Set, Subset : Row, Column )
```

Query the interest points of the descriptor model or the last processed search image.

With the operator `get_descriptor_model_points` interest points of the descriptor model or the last processed search image can be queried. It requires a `ModelID` returned by `create_uncalib_descriptor_model`, `create_calib_descriptor_model` or `read_descriptor_model`.

The interest points stored in the model can always be queried by setting `Set` to 'model' and `Subset` to 'all'. If a `find_uncalib_descriptor_model` or `find_calib_descriptor_model` precedes, with `get_descriptor_model_points` the interest points of the last search image can be queried as well by setting `Set` to 'search' and `Subset` to 'all'. Additionally, the matched (corresponding) points for each object instance found can be queried by setting `Set` to 'model' or 'search' (for the correspondences on the model or search image side, respectively) and `Subset` to the result number of the instance. The image coordinates of the queried points are returned in `Row` and `Column`.

---
18.4. DESCRIPTOR-BASED

--- Parameters ---

- **ModelID** (input_control) 
  The handle to the descriptor model.
- **Set** (input_control) 
  Set of interest points.
  **Default value:** 'model'
  **List of values:** Set ∈ {'model', 'search'}
- **Subset** (input_control) 
  Subset of interest points.
  **Default value:** 'all'
  **Suggested values:** Subset ∈ {'all', 0, 1, 2}
- **Row** (output_control) 
  Row coordinates of interest points.
  **Default value:** 'all'
  **Suggested values:** Subset ∈ {'all', 0, 1, 2}
- **Column** (output_control) 
  Column coordinates of interest points.

--- Example ---

```halcon
create_uncalib_descriptor_model (Template,'harris',[],[],[],[],42, \ ModelID)
* Model points can be queried from a model, even if just created
get_descriptor_model_points (ModelID,'model','all',ModelRow,ModelColumn)
fnd_uncalib_descriptor_model (Image,ModelID,[],[],[],[],0.2,1, \ 'num_points',HomMat2D,Score)
* Search points can be queried only after a
* find_[un]calib_descriptor_model was executed
get_descriptor_model_points (ModelID,'search','all',SearchRow,SearchColumn)
* Additionally, correspondences for the results can be queried
NumObjects := |HomMat2D|/9
for I := 0 to NumObjects-1 by 1
  * Query corresponding points in the model
    get_descriptor_model_points (ModelID,'model',I, \ CorrModelRow,CorrModelColumn)
  * Query corresponding points in the search image
    get_descriptor_model_points (ModelID,'search',I, \ CorrSearchRow,CorrSearchColumn)
  * Those points are typically for visualizational purposes
    gen_cross_contour_xld (CrossModel,CorrModelRow,CorrModelColumn, \ 6,0.78)
    gen_cross_contour_xld (CrossSearch,CorrSearchRow,CorrSearchColumn, \ 6,0.78)
  * ....
endfor
```

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Possible Predecessors ---

- `create_uncalib_descriptor_model`
- `create_calib_descriptor_model`
- `find_uncalib_descriptor_model`
- `find_calib_descriptor_model`
- `read_descriptor_model`
get_descriptor_model_results ( : : ModelID, ObjectID, 
ResultNames : Results )

Query alphanumerical results that were accumulated during descriptor-based matching.

The operator get_descriptor_model_results allows to access alphanumerical results of the descriptor-based matching process. The results are stored in a descriptor model specified by ModelID. ObjectID specifies for which object the results should be returned. The objects are 0-based indexed and in the same order as they are detected by find_uncalib_descriptor_model or find_calib_descriptor_model, respectively. Results can be queried for all objects at once by specifying 'all' in ObjectID, if they are single valued (e.g., ResultNames='num_points' or ResultNames='inlier_ratio'). The results returned in Results can be selected by setting ResultNames to:

'num_points': number of object points that correspond to model points.
'inlier_ratio': ratio of successfully matched object points relative to all descriptor model points.
'homography': a 3x3 projective transformation matrix which transforms model points into object points. Note that the result of the mapping depends on the selected model origin (see set_descriptor_model_origin).
'pose': returns the estimated object pose. Note that this result can only be queried after find_calib_descriptor_model was called.
'point_classification': returns concatenated triads representing the classification results for the interest points extracted from the search image during the last call of find_uncalib_descriptor_model or find_calib_descriptor_model. Each triad consists of a search point index on the first, a model point index on the second, and a classification score on the third position. The search and model point indices correspond to the point coordinates returned by get_descriptor_model_points with the parameter Subset set to 'all' and the parameter Set set to 'search' and 'model', respectively. If a number is passed in ObjectID only the classification results for the points matched to this object are returned. If 'all' is passed in ObjectID the classification results for all points, including the points not matched to any object, are returned. The triads are sorted in descending order with respect to their score. Points having a score less than the value of the descriptor parameter 'min_score_descr' (see find_calib_descriptor_model or find_uncalib_descriptor_model) are rejected and are not listed in the resulting classification results.

Parameters

ModelID (input_control) descriptor_model ~ handle
Handle of a descriptor model.

ObjectID (input_control) integer ~ integer / string
Handle of the object for which the results are queried.
Default value: 'all'
Suggested values: ObjectID ∈ {'all', 0, 1, 2, 3}

ResultNames (input_control) attribute.name ~ string
Name of the results to be queried.
Default value: 'num_points'
List of values: ResultNames ∈ {'num_points', 'inlier_ratio', 'homography', 'pose', 'point_classification'}

Results (output_control) attribute.value(-array) ~ string / integer / real
Returned results.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

generate_model_origin, generate_model_params, generate_model_points

Module

Matching

read_descriptor_model ( : : FileName : ModelID )

Read a descriptor model from a file.

The operator read_descriptor_model reads a descriptor model, which has been written with write_descriptor_model, from the file FileName. The default HALCON file extension for the descriptor model is ‘dsm’.

Parameters

 FileName (input_control) .................................................. filename.read  ~> string
 File name.
 File extension: .dsm
 ModelID (output_control) .............................................. descriptor_model  ~> handle
 Handle of the model.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

find_uncalib_descriptor_model, find_calib_descriptor_model

See also

create_calib_descriptor_model, create_uncalib_descriptor_model

Module

Matching

serialize_descriptor_model ( : : ModelID : SerializedItemHandle )

Serialize a descriptor model.

serialize_descriptor_model serializes the data of a descriptor model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_descriptor_model is converted to a serialized item. The descriptor model is defined by the handle ModelID. The serialized descriptor model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_descriptor_model.

Parameters

 ModelID (input_control) .............................................. descriptor_model  ~> handle
 Handle of a model to be saved.

SerializedItemHandle (output_control) ................................ serialized_item  ~> handle
 Handle of the serialized item.
### Result

If the parameters are valid, the operator `serialize_descriptor_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Matching**

---

**set_descriptor_model_origin** ( : : ModelID, Row, Column : )

Sets the origin of a descriptor model.

The operator `set_descriptor_model_origin` sets the origin (reference point) of the descriptor model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the descriptor model with `create_uncalib_descriptor_model` or `create_calib_descriptor_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity. The new setting affects the succeeding `find_uncalib_descriptor_model` and `find_calib_descriptor_model` calls.

### Parameters

- **ModelID** (input_control) : descriptor_model ~ handle
  Handle of a descriptor model.
- **Row** (input_control) : real ~ real / integer
  Translation of origin in row direction.
  Default value: 0
- **Column** (input_control) : real ~ real / integer
  Translation of origin in column direction.
  Default value: 0

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `create_uncalib_descriptor_model`, `create_calib_descriptor_model`, `read_descriptor_model`
18.5. SHAPE-BASED

get_descriptor_model_origin, create_uncalib_descriptor_model

Module

write_descriptor_model ( : : ModelID, FileName : )

Write a descriptor model to a file.
The operator write_descriptor_model writes a descriptor model to the file FileName. The model can be
read again with read_descriptor_model. The default HALCON file extension for the descriptor model is
'dsm'.

Parameters

▷ ModelID (input_control) .................................................. descriptor_model ~ handle
Handle of a model to be saved.
▷ FileName (input_control) .................................................. filename.write ~ string
The path and filename of the model to be saved.
File extension: .dsm

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
points_lepetit, create_uncalib_descriptor_model, create_calib_descriptor_model

Module

Matching

18.5 Shape-Based

clear_shape_model ( : : ModelID : )

Free the memory of a shape model.
The operator clear_shape_model frees the memory of a shape model that was created by
clear_shape_model, create_scaled_shape_model, or create_aniso_shape_model. After
calling clear_shape_model, the model can no longer be used. The handle ModelID becomes invalid.

Parameters

▷ ModelID (input_control) .................................................. shape_model ~ handle
Handle of the model.

Result

If the handle of the model is valid, the operator clear_shape_model returns the value 2 (H_MSG_TRUE). If
necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_shape_model, create_scaled_shape_model, create_aniso_shape_model, read_shape_model, write_shape_model

Matching

create_aniso_shape_model ( Template : : NumLevels, AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, Contrast, MinContrast : ModelID )

Prepare an anisotropically scaled shape model for matching.

The operator create_aniso_shape_model prepares a template, which is passed in the image Template, as an anisotropically scaled shape model used for matching. The ROI of the model is passed as the domain of Template.

The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_aniso_shape_model. The center of gravity of the domain (region) of the model image Template is used as the origin (reference point) of the model. A different origin can be set with set_shape_model_origin. The model is generated using multiple image pyramid levels and is stored in memory.

If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and anisotropic scales (i.e., independent scales in the row and column direction) on each level. The model can be extended by clutter parameters with set_shape_model_clutter.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of inspect_shape_model. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_aniso_shape_model returns with an error message.

If NumLevels is set to 'auto' (or 0 for backwards compatibility), create_aniso_shape_model determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_aniso_shape_model determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_aniso_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_aniso_shape_model may increase. In these cases, the number of pyramid levels should be selected using the output of inspect_shape_model.

AngleStart, AngleExtent and AngleStep: The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by find_aniso_shape_model. The parameter AngleStep determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in find_aniso_shape_model, this parameter specifies the accuracy that is achievable for the angles in find_aniso_shape_model. AngleStep should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence AngleStep should be chosen
larger for smaller models. If **AngleExtent** is not an integer multiple of **AngleStep**, **AngleStep** is modified accordingly.

To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_aniso_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value `n` such that **AngleStart** plus `n` times **AngleStep** is exactly 0.0, **AngleStart** is decreased by up to **AngleStep** and **AngleExtent** is increased by **AngleStep**.

**ScaleRMin**, **ScaleRMax**, **ScaleCMin**, **ScaleCMax**, **ScaleRStep** and **ScaleCStep**: The parameters

**ScaleRMin**, **ScaleRMax**, **ScaleCMin**, **ScaleCMax**, and **ScaleCStep** determine the range of possible anisotropic scales of the model in the row and column direction. A scale of 1 in both scale factors corresponds to the original size of the model. The parameters **ScaleRStep** and **ScaleCStep** determine the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, these parameters specify the accuracy that is achievable for the scales in `find_aniso_shape_model`. Like **AngleStep**, **ScaleRStep** and **ScaleCStep** should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of **ScaleRStep** and **ScaleCStep** and **ScaleRStep** and **ScaleCStep** are modified accordingly.

To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_aniso_shape_model`, the range of possible scales is modified as follows: If there are no positive integer values `n` and `m` such that **ScaleRMin** plus `n` times **ScaleRStep** is exactly 1.0 and **ScaleCMin** plus `m` times **ScaleCStep** is exactly 1.0, **ScaleRMin** and **ScaleCMin** are decreased by up to **ScaleRStep** and **ScaleCStep**, respectively, and **ScaleRMax** and **ScaleCMax** are increased such that the range of possible scales is increased by **ScaleRStep** and **ScaleCStep**, respectively.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

**Optimization**: For particularly large models, it may be useful to reduce the number of model points by setting **Optimization** to a value different from 'none'. If **Optimization** = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of **Optimization**. If the number of points is reduced, it may be necessary in `find_aniso_shape_model` to set the parameter **Greediness** to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If **Optimization** is set to 'auto', `create_aniso_shape_model` automatically determines the reduction of the number of model points.

**Metric**: The parameter **Metric** determines the conditions under which the model is recognized in the image.

If **Metric** = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If **Metric** = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_aniso_shape_model` will increase slightly in this case.

If **Metric** = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_aniso_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_aniso_shape_model`, and to match them simultaneously with `find_aniso_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If **Metric** = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_aniso_shape_model` can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for **Metric** = 'ignore_color_polarity' the number of channels in the model creation with `create_aniso_shape_model` and in the search with `find_aniso_shape_model` can be different. This can, for example, be used to create a model from a...
Contrast: The parameter Contrast determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. Contrast should be chosen such that only the significant features of the template are used for the model. Contrast can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in edges_image. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see hysteresis_threshold. Optionally, Contrast can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in Contrast. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with inspect_shape_model.

If Contrast is set to 'auto', create_aniso_shape_model determines the three above described values automatically. Besides, only the contrast ('auto_contrast'), the hysteresis thresholds ('auto_contrast_hyst'), or the minimum size ('auto_min_size') can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, ['auto_contrast', 'auto_min_size'] is passed, both the contrast and the minimum size are determined automatically. If ['auto_min_size', 20, 30] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with determine_shape_model_params and subsequently verified using inspect_shape_model before calling create_aniso_shape_model. Note that MinContrast influences the automatic contrast estimation, and hence also the estimation of the minimum size.

MinContrast: With MinContrast, it can be determined which contrast the model must at least have in the recognition performed by find_aniso_shape_model. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast should be set to 17. Obviously, MinContrast must be smaller than Contrast. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_aniso_shape_model.

If MinContrast is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using get_shape_model_params.

Complete pregeneration of the model

Optionally, a second value can be passed in Optimization. This value determines whether the model is pregenerated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models', ...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However,
in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_aniso_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if `AngleStep`, `ScaleRStep`, or `ScaleCStep` are too small or `AngleExtent` or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, `create_aniso_shape_model` must be enlarged or `AngleExtent` or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_aniso_shape_model`, `AngleStep ≥ 1°` and `ScaleRStep, ScaleCStep ≥ 0.02` can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep = 'auto'` or `ScaleRStep, ScaleCStep = 'auto'` (or 0 for backwards compatibility in both cases) is selected, `create_aniso_shape_model` automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in `find_aniso_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

### Parameters

- **Template** (input_object) ......................................................... (multichannel-)image  \(\sim\) **object**: byte / uint2
  - Input image whose domain will be used to create the model.

- **NumLevels** (input_control) ................................................. integer  \(\sim\) integer / string
  - Maximum number of pyramid levels.
  - **Default value:** 'auto'
  - **List of values:** NumLevels ∈ ['auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

- **AngleStart** (input_control) .............................................. angle.rad  \(\sim\) real
  - Smallest rotation of the pattern.
  - **Default value:** -0.39
  - **Suggested values:** AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]

- **AngleExtent** (input_control) ............................................. angle.rad  \(\sim\) real
  - Extent of the rotation angles.
  - **Default value:** 0.79
  - **Suggested values:** AngleExtent ∈ [6.29, 3.14, 1.57, 0.79, 0.39]
  - **Restriction:** AngleExtent ≥ 0

- **AngleStep** (input_control) .............................................. angle.rad  \(\sim\) real / string
  - Step length of the angles (resolution).
  - **Default value:** 'auto'
  - **Suggested values:** AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]
  - **Restriction:** AngleStep ≥ 0 & & AngleStep ≤ pi / 16

- **ScaleRMin** (input_control) .............................................. number  \(\sim\) real
  - Minimum scale of the pattern in the row direction.
  - **Default value:** 0.9
  - **Suggested values:** ScaleRMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  - **Restriction:** ScaleRMin > 0

HALCON 20.05.0.0
\[ \text{ScaleRMax} \ \text{(input\_control)} \quad \text{number} \sim \text{real} \]
Maximum scale of the pattern in the row direction.
Default value: 1.1
Suggested values: \( \text{ScaleRMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\} \)
Restriction: \( \text{ScaleRMax} \geq \text{ScaleRMin} \)

\[ \text{ScaleRStep} \ \text{(input\_control)} \quad \text{number} \sim \text{real/ string} \]
Scale step length (resolution) in the row direction.
Default value: ‘auto’
Suggested values: \( \text{ScaleRStep} \in \{\text{’auto’, 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}\} \)
Restriction: \( \text{ScaleRStep} \geq 0 \)

\[ \text{ScaleCMin} \ \text{(input\_control)} \quad \text{number} \sim \text{real} \]
Minimum scale of the pattern in the column direction.
Default value: 0.9
Suggested values: \( \text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
Restriction: \( \text{ScaleCMin} > 0 \)

\[ \text{ScaleCMax} \ \text{(input\_control)} \quad \text{number} \sim \text{real} \]
Maximum scale of the pattern in the column direction.
Default value: 1.1
Suggested values: \( \text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\} \)
Restriction: \( \text{ScaleCMax} \geq \text{ScaleCMin} \)

\[ \text{Optimization} \ \text{(input\_control)} \quad \text{string(-array)} \sim \text{string} \]
Kind of optimization and optionally method used for generating the model.
Default value: ‘auto’
List of values: \( \text{Optimization} \in \{\text{’auto’, ’none’, ’point_reduction_low’, ’point_reduction_medium’, ’point_reduction_high’, ’pregeneration’, ’no_pregeneration’}\} \)

\[ \text{Metric} \ \text{(input\_control)} \quad \text{string} \sim \text{string} \]
Match metric.
Default value: ‘use_polarity’
List of values: \( \text{Metric} \in \{\text{’use_polarity’, ’ignore_global_polarity’, ’ignore_local_polarity’, ’ignore_color_polarity’}\} \)

\[ \text{Contrast} \ \text{(input\_control)} \quad \text{number(-array)} \sim \text{integer/ string} \]
Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
Default value: ‘auto’
Suggested values: \( \text{Contrast} \in \{\text{’auto’, ’auto_contrast’, ’auto_contrast_hyst’, ’auto_min_size’, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}\} \)

\[ \text{MinContrast} \ \text{(input\_control)} \quad \text{number} \sim \text{integer/ string} \]
Minimum contrast of the objects in the search images.
Default value: ‘auto’
Suggested values: \( \text{MinContrast} \in \{\text{’auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40}\} \)
Restriction: \( \text{MinContrast} < \text{Contrast} \)

\[ \text{ModelID} \ \text{(output\_control)} \quad \text{shape\_model} \sim \text{handle} \]
Handle of the model.

--- Result ---
If the parameters are valid, the operator \text{create\_aniso\_shape\_model} returns the value 2 (H MSG TRUE).
If necessary an exception is raised. If the parameters \text{NumLevels} and \text{Contrast} are chosen such that the model contains too few points, the error 8510 is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors: draw_region, reduce_domain, threshold

Possible Successors: find_aniso_shape_model, find_aniso_shape_models, get_shape_model_params, clear_shape_model, write_shape_model, set_shape_model_origin, set_shape_model_clutter

Alternatives: create_shape_model, create_scaled_shape_model

See also: set_system, get_system

Module: Matching

create_aniso_shape_model_xld ( Contours : : NumLevels, AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, MinContrast : ModelID )

Prepare an anisotropically scaled shape model for matching from XLD contours.

The operator create_aniso_shape_model_xld creates an anisotropically scaled shape model used for matching from the XLD contours passed in Contours. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator create_aniso_shape_model, which creates a shape model from a template image, the operator create_aniso_shape_model_xld creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_aniso_shape_model. The center of gravity of the smallest surrounding rectangle of the Contours that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with set_shape_model_origin. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and anisotropic scales (i.e., independent scales in the row and column direction) on each level. The model can be extended by clutter parameters with set_shape_model_clutter.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, create_aniso_shape_model_xld returns with an error message. If NumLevels is set to ‘auto’, create_aniso_shape_model_xld determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_aniso_shape_model_xld determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_aniso_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_aniso_shape_model may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent and AngleStep: The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the object can occur in the image. Note that the object can only
be found in this range of angles by `find_aniso_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_aniso_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_aniso_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value \( n \) such that \( \text{AngleStart} + n \times \text{AngleStep} \) is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

**ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, ScaleRStep and ScaleCStep:** The parameters `ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax` determine the range of possible anisotropic scales of the object in the row and column direction. A scale of 1 in both scale factors corresponds to the original size of the model. The parameters `ScaleRStep` and `ScaleCStep` determine the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, these parameters specify the accuracy that is achievable for the scales in `find_aniso_shape_model`. Like `AngleStep`, `ScaleRStep` and `ScaleCStep` should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of `ScaleRStep` and `ScaleCStep`, `ScaleRStep` and `ScaleCStep` are modified accordingly.

To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_aniso_shape_model`, the range of possible scales is modified as follows: If there are no positive integer values \( n \) and \( m \) such that `ScaleRMin + n \times ScaleRStep` is exactly 1.0 and `ScaleCMin + m \times ScaleCStep` is exactly 1.0, `ScaleRMin` and `ScaleCMin` are increased by up to `ScaleRStep` and `ScaleCStep`, respectively, and `ScaleRMax` and `ScaleCMax` are increased such that the range of possible scales is increased by `ScaleRStep` and `ScaleCStep`, respectively.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

**Optimization:** For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `'none'`. If `Optimization = 'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_aniso_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to `'auto'`, `create_aniso_shape_model_xld` automatically determines the reduction of the number of model points.

**Metric:** The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_aniso_shape_model` will increase slightly in this case.

Note that the metrics (`'use_polarity'` and `ignore_global_polarity`) can only be selected if all `Contours` provide the attribute `edge_direction`, which defines the polarity of the edges. This attribute is available for contours created, e.g., with `edges_sub_pix` with the parameter `Method` set to, e.g., `'canny'`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

If `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_aniso_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_aniso_shape_model_xld`, and to match them simultaneously with `find_aniso_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).
If `Metric` = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance which channels the object is visible. In this mode, the runtime of `find_aniso_shape_model` can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'.

It should be noted that for `Metric` = 'ignore_color_polarity' the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all `Contours` provide the attribute 'edge_direction', which defines the polarity of the edges. For more information about contour attributes like 'edge_direction' see `get_contour_attrib_xld`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

**Complete pregeneration of the model**

Optionally, a second value can be passed in Optimization. This value determines whether the model is pregenerated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., only one value is passed), the mode that is set with `set_system('pregenerate_shape_models',...)` is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_aniso_shape_model` typically returns slightly lower scores, which may require setting a correspondingly smaller value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if `AngleStep`, `ScaleRStep`, or `ScaleCStep` are too small or `AngleExtent` or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, `AngleStep`, `ScaleRStep`, or `ScaleCStep` must be enlarged or `AngleExtent` or the range of scales must be reduced. If this is not possible, the model is pregenerated using subpixel resolution by `find_aniso_shape_model.AngleStep ≥ 1°` and `ScaleRStep, ScaleCStep ≥ 0.02` can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep` = 'auto' or `ScaleRStep, ScaleCStep = 'auto'` is selected, `create_aniso_shape_model_xld` automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in
find_aniso_shape_model. Because of this, the recognition of the model might require slightly more time. Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

The XLD contours passed in Contours should have been scaled to approximately the average size of the object in the search images. This means that the products ScaleRMin \times ScaleRMax and ScaleCMin \times ScaleCMax should be approximately equal to 1.

Note that, in contrast to the operator create_aniso_shape_model, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling create_aniso_shape_model_xld with the operator select_contours_xld.

Parameters

\begin{itemize}
  \item \texttt{Contours} (input_object) \hspace{1cm} \text{xld_cont(-array)} \sim \text{object}

  Input contours that will be used to create the model.

  \item \texttt{NumLevels} (input_control) \hspace{1cm} \text{integer}

  Maximum number of pyramid levels.

  Default value: 'auto'

  List of values: NumLevels \in \{ 'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \}

  \item \texttt{AngleStart} (input_control) \hspace{1cm} \text{angle.rad} \sim \text{real}

  Smallest rotation of the pattern.

  Default value: -0.39

  Suggested values: AngleStart \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}

  \item \texttt{AngleExtent} (input_control) \hspace{1cm} \text{angle.rad} \sim \text{real}

  Extent of the rotation angles.

  Default value: 0.79

  Suggested values: AngleExtent \in \{ 6.29, 3.14, 1.57, 0.79, 0.39 \}

  Restriction: AngleExtent > 0

  \item \texttt{AngleStep} (input_control) \hspace{1cm} \text{angle.rad} \sim \text{real} / \text{string}

  Step length of the angles (resolution).

  Default value: 'auto'

  Suggested values: AngleStep \in \{'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873 \}

  Restriction: AngleStep > 0 && AngleStep <= \pi / 16

  \item \texttt{ScaleRMin} (input_control) \hspace{1cm} \text{number} \sim \text{real}

  Minimum scale of the pattern in the row direction.

  Default value: 0.9

  Suggested values: ScaleRMin \in \{ 0.5, 0.6, 0.7, 0.8, 0.9, 1.0 \}

  Restriction: ScaleRMin > 0

  \item \texttt{ScaleRMax} (input_control) \hspace{1cm} \text{number} \sim \text{real}

  Maximum scale of the pattern in the row direction.

  Default value: 1.1

  Suggested values: ScaleRMax \in \{ 1.0, 1.1, 1.2, 1.3, 1.4, 1.5 \}

  Restriction: ScaleRMax >= ScaleRMin

  \item \texttt{ScaleRStep} (input_control) \hspace{1cm} \text{number} \sim \text{real} / \text{string}

  Scale step length (resolution) in the row direction.

  Default value: 'auto'

  Suggested values: ScaleRStep \in \{'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2 \}

  Restriction: ScaleRStep > 0

  \item \texttt{ScaleCMin} (input_control) \hspace{1cm} \text{number} \sim \text{real}

  Minimum scale of the pattern in the column direction.

  Default value: 0.9

  Suggested values: ScaleCMin \in \{ 0.5, 0.6, 0.7, 0.8, 0.9, 1.0 \}

  Restriction: ScaleCMin > 0

  \item \texttt{ScaleCMax} (input_control) \hspace{1cm} \text{number} \sim \text{real}

  Maximum scale of the pattern in the column direction.

  Default value: 1.1

  Suggested values: ScaleCMax \in \{ 1.0, 1.1, 1.2, 1.3, 1.4, 1.5 \}

  Restriction: ScaleCMax >= ScaleCMin
\end{itemize}
18.5. SHAPE-BASED

SHAPE-BASED

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Result

If the parameters are valid, the operator create_aniso_shape_model_xld returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter NumLevels is chosen such that the model contains too few points, the error 8510 is raised.

Matching

prepare_an_isotropically_scaled_shape_model ( Template : : NumLevels, AngleStart, AngleExtent, AngleStep, ScaleMin, ScaleMax, ScaleStep, Optimization, Metric, Contrast, MinContrast : : ModelID )

Prepare an isotropically scaled shape model for matching.

The operator prepare_an_isotropically_scaled_shape_model prepares a template, which is passed in the image Template, as an isotropically scaled shape model used for matching. The ROI of the model is passed as the domain of Template.
The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of `inspect_shape_model`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_scaled_shape_model` returns with an error message.

If `NumLevels` is set to ‘auto’ (or 0 for backwards compatibility), `create_scaled_shape_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_scaled_shape_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness. If the number of pyramid levels is chosen too small, the time required to find the model in `find_scaled_shape_model` may increase. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

`AngleStart`, `AngleExtent` and `AngleStep`: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_scaled_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_scaled_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_scaled_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

`ScaleMin`, `ScaleMax` and `ScaleStep`: The parameters `ScaleMin` and `ScaleMax` determine the range of possible scales (sizes) of the model. A scale of 1 corresponds to the original size of the model. The parameter `ScaleStep` determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the scales in `find_scaled_shape_model`. `ScaleStep` should be chosen based on the size of the object. If the range of scales is not an integer multiple of `ScaleStep`, `ScaleStep` is modified accordingly. To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_scaled_shape_model`, the range of possible scales is modified as follows: If there is no positive integer value n such that `ScaleMin` plus n times `ScaleStep` is exactly 1.0, `ScaleMin` is decreased by up to `ScaleStep` and `ScaleMax` is increased such that the range of possible scales is increased by `ScaleStep`.

`Optimization`: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from ‘none’. If `Optimization = 'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_scaled_shape_model` to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to ‘auto’, `create_scaled_shape_model` automatically determines the reduction of the number of model points.
**Metric**: The parameter **Metric** determines the conditions under which the model is recognized in the image. If **Metric** = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If **Metric** = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_scaled_shape_model will increase slightly in this case.

If **Metric** = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of find_scaled_shape_model increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with create_scaled_shape_model, and to match them simultaneously with find_scaled_shape_models.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If **Metric** = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of find_scaled_shape_model can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'.

**Contrast**: The parameter **Contrast** determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. **Contrast** should be chosen such that only the significant features of the template are used for the model. **Contrast** can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in edges_image. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see hysteresis_threshold. Optionally, **Contrast** can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in **Contrast**. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with inspect_shape_model.

If **Contrast** is set to 'auto', create_scaled_shape_model determines the three above described values automatically. Besides, only the contrast ('auto_contrast'), the hysteresis thresholds ('auto_contrast_hyst'), or the minimum size ('auto_min_size') can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, ['auto_contrast','auto_min_size'] is passed, both the contrast and the minimum size are determined automatically. If ['auto_min_size',20,30] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with determine_shape_model_params and subsequently verified using inspect_shape_model before calling create_scaled_shape_model.

Note that MinContrast influences the automatic contrast estimation, and hence also the estimation of the minimum size.

**MinContrast**: With MinContrast, it can be determined which contrast the model must at least have in the recognition performed by find_scaled_shape_model. In other words, this parameter separates the
model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, \( \text{MinContrast} \) should be set to 10. If multichannel images are used for the model and the search images, and if the parameter \( \text{Metric} \) is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine \( \text{MinContrast} \). If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image \( \text{MinContrast} \) should be set to 17. Obviously, \( \text{MinContrast} \) must be smaller than \( \text{Contrast} \). If the model should be recognized in very low contrast images, \( \text{MinContrast} \) must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, \( \text{MinContrast} \) should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by \text{find_scaled_shape_model}.

If \( \text{MinContrast} \) is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using \text{get_shape_model_params}.

### Complete pregeneration of the model

Optionally, a second value can be passed in \text{Optimization}. This value determines whether the model is pregenerated completely or not. To do so, the second value of \text{Optimization} must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with \text{set_system('pregenerate_shape_models',...)} is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, \text{find_scaled_shape_model} typically returns slightly lower scores, which may require setting a slightly lower value for \( \text{MinScore} \) than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if \( \text{AngleStep} \) or \( \text{ScaleStep} \) are too small or \( \text{AngleExtent} \) or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either \( \text{AngleStep} \) or \( \text{ScaleStep} \) must be enlarged or \( \text{AngleExtent} \) or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by \text{find_scaled_shape_model}, \( \text{AngleStep} \geq 1^\circ \) and \( \text{ScaleStep} \geq 0.02 \) can be selected for models of a diameter smaller than about 200 pixels.

If \( \text{AngleStep} = 'auto' \) or \( \text{ScaleStep} = 'auto' \) (or 0 for backwards compatibility in both cases) is selected, \text{create_scaled_shape_model} automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using \text{get_shape_model_params}.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in \text{find_scaled_shape_model}. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

---

**Parameters**

- **Template**: (input_object) ......................... (multichannel-)image \( \sim \) object : byte / uint2
  - Input image whose domain will be used to create the model.
**SHAPA-BASED**

- **NumLevels** (input_control) ... integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: `NumLevels ∈ {‘auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}`

- **AngleStart** (input_control) ... angle.rad ~ real
  Smallest rotation of the pattern.
  Default value: -0.39
  Suggested values: `AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]`
  Restriction: `AngleStart ≥ 0`

- **AngleExtent** (input_control) ... angle.rad ~ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: `AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}`
  Restriction: `AngleExtent ≥ 0`

- **AngleStep** (input_control) ... angle.rad ~ real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: `AngleStep ∈ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}`
  Restriction: `AngleStep ≥ 0 && AngleStep <= pi / 16`

- **ScaleMin** (input_control) ... number ~ real
  Minimum scale of the pattern.
  Default value: 0.9
  Suggested values: `ScaleMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}`
  Restriction: `ScaleMin > 0`

- **ScaleMax** (input_control) ... number ~ real
  Maximum scale of the pattern.
  Default value: 1.1
  Suggested values: `ScaleMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}`
  Restriction: `ScaleMax ≥ ScaleMin`

- **ScaleStep** (input_control) ... number ~ real / string
  Scale step length (resolution).
  Default value: 'auto'
  Suggested values: `ScaleStep ∈ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}`
  Restriction: `ScaleStep ≥ 0`

- **Optimization** (input_control) ... string(-array) ~ string
  Kind of optimization and optionally method used for generating the model.
  Default value: 'auto'
  List of values: `Optimization ∈ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'}`

- **Metric** (input_control) ... string ~ string
  Match metric.
  Default value: 'use_polarity'
  List of values: `Metric ∈ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}`

- **Contrast** (input_control) ... number(-array) ~ integer / string
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
  Default value: 'auto'
  Suggested values: `Contrast ∈ {'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}`

- **MinContrast** (input_control) ... number ~ integer / string
  Minimum contrast of the objects in the search images.
  Default value: 'auto'
  Suggested values: `MinContrast ∈ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}`
  Restriction: `MinContrast < Contrast`

- **ModelID** (output_control) ... shape_model ~ handle
  Handle of the model.

If the parameters are valid, the operator `create_scaled_shape_model` returns the value 2.
If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, the error 8510 is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Module**

**create_scaled_shape_model_xld**

```
create_scaled_shape_model_xld ( Contours : : NumLevels,
                                AngleStart, AngleExtent, AngleStep, ScaleMin, ScaleMax,
                                ScaleStep, Optimization, Metric, MinContrast : ModelID)
```

Prepare an isotropically scaled shape model for matching from XLD contours.

The operator `create_scaled_shape_model_xld` creates an isotropically scaled shape model used for matching from the XLD contours passed in `Contours`. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator `create_scaled_shape_model`, which creates a shape model from a template image, the operator `create_scaled_shape_model_xld` creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_scaled_shape_model`. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and scales on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

**Input parameters in detail**

**NumLevels**: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_scaled_shape_model_xld` returns with an error message. If `NumLevels` is set to `'auto'`, `create_scaled_shape_model_xld` determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_scaled_shape_model_xld` determines a value for the number of pyramid levels that...
is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_scaled_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_scaled_shape_model may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent and AngleStep: The parameters AngleStart and AngleExtent determine the range of possible scales (sizes) of the object. A scale of 1 corresponds to the original size of the model. The parameter ScaleStep determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in find_scaled_shape_model, this parameter specifies the accuracy that is achievable for the angles in find_scaled_shape_model. AngleStep should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence AngleStep should be chosen larger for smaller models. If AngleExtent is not an integer multiple of AngleStep, AngleStep is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by find_scaled_shape_model, the range of possible rotations is modified as follows: If there is no positive integer value n such that AngleStart plus n times AngleStep is exactly 0.0, AngleStart is decreased by up to AngleStep and AngleExtent is increased by AngleStep.

ScaleMin, ScaleMax and ScaleStep: The parameters ScaleMin and ScaleMax determine the range of possible scales (sizes) of the object. A scale of 1 corresponds to the original size of the model. The parameter ScaleStep determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in find_scaled_shape_model, this parameter specifies the accuracy that is achievable for the scales in find_scaled_shape_model. Like AngleStep, ScaleStep should be chosen based on the size of the object. If the range of scales is not an integer multiple of ScaleStep, ScaleStep is modified accordingly. To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by find_scaled_shape_model, the range of possible scales is modified as follows: If there is no positive integer value n such that ScaleMin plus n times ScaleStep is exactly 1.0, ScaleMin is decreased by up to ScaleStep and ScaleMax is increased such that the range of possible scales is increased by ScaleStep.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_scaled_shape_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If Optimization is set to 'auto', create_scaled_shape_model_xld automatically determines the reduction of the number of model points.

Metric: The parameter Metric determines the conditions under which the model is recognized in the image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_scaled_shape_model will increase slightly in this case.

Note that the metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. This attribute is available for contours created, e.g., with edges_sub_pix with the parameter Method set to, e.g., 'canny'. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

If Metric = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of find_scaled_shape_model increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with create_scaled_shape_model_xld, and to match them simultaneously with find_scaled_shape_models.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).
If \texttt{Metric = 'ignore\_color\_polarity'}, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of \texttt{find\_scaled\_shape\_model} can also increase significantly. The metric \texttt{'ignore\_color\_polarity'} can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as \texttt{'ignore\_local\_pol}\_arity'. It should be noted that for \texttt{Metric = 'ignore\_color\_polarity'} the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics (\texttt{'use\_polarity'} and \texttt{'ignore\_global\_polarity'}) can only be selected if all \texttt{Contours} provide the attribute \texttt{'edge\_direction'}, which defines the polarity of the edges. For more information about contour attributes like \texttt{'edge\_direction'} see \texttt{get\_contour\_attrib\_xld}. Otherwise, these two metrics can be selected with the operator \texttt{set\_shape\_model\_metric}, which determines the polarity of the edges from an image.

**MinContrast:** With \texttt{MinContrast}, it can be determined which contrast the object edges must at least have in the recognition performed by \texttt{find\_scaled\_shape\_model}. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, \texttt{MinContrast} should be set to 10. If multichannel images are used for the model and the search images, and if the parameter \texttt{Metric} is set to \texttt{'ignore\_color\_polarity'} (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine \texttt{MinContrast}. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image \texttt{MinContrast} should be set to 17. If the model should be recognized in very low contrast images, \texttt{MinContrast} must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, \texttt{MinContrast} should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by \texttt{find\_scaled\_shape\_model}.

### Complete pregeneration of the model

Optionally, a second value can be passed in \texttt{Optimization}. This value determines whether the model is pregenerated completely or not. To do so, the second value of \texttt{Optimization} must be set to either \texttt{'pregeneration'} or \texttt{'no\_pregeneration'}. If the second value is not used (i.e., if only one value is passed), the mode that is set with \texttt{set\_system('pregenerate\_shape\_models',...)} is used. With the default value (\texttt{'pregenerate\_shape\_models' = 'false'}), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, \texttt{find\_scaled\_shape\_model} typically returns slightly lower scores, which may require setting a slightly lower value for \texttt{MinScore} than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if \texttt{AngleStep} or \texttt{ScaleStep} are too small or \texttt{AngleExtent} or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either \texttt{AngleStep} or \texttt{ScaleStep} must be enlarged or \texttt{AngleExtent} or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by \texttt{find\_scaled\_shape\_model}, \texttt{AngleStep} ≥ 1° and \texttt{ScaleStep} ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If \texttt{AngleStep = 'auto'} or \texttt{ScaleStep = 'auto'} is selected, \texttt{create\_scaled\_shape\_model\_xld} automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using \texttt{get\_shape\_model\_params}.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in \texttt{find\_scaled\_shape\_model}. Because of this, the recognition of the model might require slightly more time.
Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

The XLD contours passed in Contours should have been scaled to approximately the average size of the object in the search images. This means that the product $\text{ScaleMin} \times \text{ScaleMax}$ should be approximately equal to 1.

Note that, in contrast to the operator create_scaled_shape_model, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling create_scaled_shape_model_xld with the operator select_contours_xld.

Parameters

- **Contours** (input_object) .... xld_cont(-array) ~ object
  Input contours that will be used to create the model.

- **NumLevels** (input_control) .......... integer ~ integer / string
  Maximum number of pyramid levels.
  Default value: ‘auto’
  List of values: $\text{NumLevels} \in \{\text{‘auto’}, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- **AngleStart** (input_control) .......... angle.rad ~ real
  Smallest rotation of the pattern.
  Default value: -0.39
  Suggested values: $\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$

- **AngleExtent** (input_control) ......... angle.rad ~ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: $\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39\}$
  Restriction: $\text{AngleExtent} \geq 0$

- **AngleStep** (input_control) .......... angle.rad ~ real / string
  Step length of the angles (resolution).
  Default value: ‘auto’
  Suggested values: $\text{AngleStep} \in \{\text{‘auto’}, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\}$
  Restriction: $\text{AngleStep} > 0$ \\ & $\text{AngleStep} \leq \pi / 16$

- **ScaleMin** (input_control) .......... number ~ real
  Minimum scale of the pattern.
  Default value: 0.9
  Suggested values: $\text{ScaleMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Restriction: $\text{ScaleMin} > 0$

- **ScaleMax** (input_control) .......... number ~ real
  Maximum scale of the pattern.
  Default value: 1.1
  Suggested values: $\text{ScaleMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
  Restriction: $\text{ScaleMax} \geq \text{ScaleMin}$

- **ScaleStep** (input_control) .......... number ~ real / string
  Scale step length (resolution).
  Default value: ‘auto’
  Suggested values: $\text{ScaleStep} \in \{\text{‘auto’}, 0.01, 0.02, 0.05, 0.1, 0.15, 0.2\}$
  Restriction: $\text{ScaleStep} > 0$

- **Optimization** (input_control) ........ string(-array) ~ string
  Kind of optimization and optionally method used for generating the model.
  Default value: ‘auto’
  List of values: $\text{Optimization} \in \{\text{‘auto’}, \text{‘none’}, \text{‘point_reduction_low’}, \text{‘point_reduction_medium’}, \text{‘point_reduction_high’}, \text{‘pregeneration’}, \text{‘no_pregeneration’}\}$

- **Metric** (input_control) .......... string ~ string
  Match metric.
  Default value: ‘ignore_local_polarity’
  List of values: $\text{Metric} \in \{\text{‘use_polarity’}, \text{‘ignore_global_polarity’}, \text{‘ignore_local_polarity’}, \text{‘ignore_color_polarity’}\}$
**MinContrast** (input_control)  
Minimum contrast of the objects in the search images.
**Default value:** 5
**Suggested values:** MinContrast ∈ {1, 2, 3, 5, 7, 10, 20, 30, 40}

**ModelID** (output_control)  
Handle of the model.

---

**Result**
If the parameters are valid, the operator `create_scaled_shape_model_xld` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter **NumLevels** is chosen such that the model contains too few points, the error 8510 is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

---

```c
create_shape_model ( Template : : NumLevels, AngleStart,
                     AngleExtent, AngleStep, Optimization, Metric, Contrast,
                     MinContrast : : ModelID )
```

**Prepare a shape model for matching.**

The operator `create_shape_model` prepares a template, which is passed in the image `Template`, as a shape model used for matching. The ROI of the model is passed as the domain of `Template`.

The output parameter **ModelID** is a handle for this model, which is used in subsequent calls to `find_shape_model`. The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated using multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

**Input parameters in detail**

**NumLevels:** The number of pyramid levels is determined with the parameter **NumLevels**. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, **NumLevels** must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of `inspect_shape_model`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_shape_model` returns with an error message.
If `NumLevels` is set to `auto` (or 0 for backwards compatibility), `create_shape_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_shape_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_shape_model` may increase. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

**AngleStart, AngleExtent and AngleStep**: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

**Optimization**: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `none`. If `Optimization` = `none`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced by `find_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to `auto`, `create_shape_model` automatically determines the reduction of the number of model points.

**Metric**: The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric` = `use_polarity`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric` = `ignore_global_polarity`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_shape_model` will increase slightly in this case.

If `Metric` = `ignore_local_polarity`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_shape_model`, and to match them simultaneously with `find_shape_model`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric` = `ignore_color_polarity`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_shape_model` can also increase significantly. The metric `ignore_color_polarity` can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as `ignore_local_polarity`. It should be noted that for `Metric` = `ignore_color_polarity` the number of channels in the model creation with `create_shape_model` and in the search with `find_shape_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

**Contrast**: The parameter `Contrast` determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of
the object. **Contrast** should be chosen such that only the significant features of the template are used for the model. **Contrast** can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, **Contrast** can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in **Contrast**. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with `inspect_shape_model`.

If **Contrast** is set to 'auto', `create_shape_model` determines the three above described values automatically. only the contrast ('auto_contrast'), the hysteresis thresholds ('auto_contrast_hyst'), or the minimum size ('auto_min_size') can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, ['auto_contrast', 'auto_min_size'] is passed, both the contrast and the minimum size are determined automatically. If ['auto_min_size', 20, 30] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_shape_model_params` and subsequently verified using `inspect_shape_model` before calling `create_shape_model`. Note that **MinContrast** influences the automatic contrast estimation, and hence also the estimation of the minimum size.

**MinContrast**: With **MinContrast**, it can be determined which contrast the model must at least have in the recognition performed by `find_shape_model`. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, **MinContrast** should be set to 10. If multichannel images are used for the model and the search images, and if the parameter **Metric** is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine **MinContrast**. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image **MinContrast** should be set to 17. Obviously, **MinContrast** must be smaller than **Contrast**. If the model should be recognized in very low contrast images, **MinContrast** must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, **MinContrast** should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_shape_model`.

If **MinContrast** is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using `get_shape_model_params`.

**Complete pregeneration of the model**

Optionally, a second value can be passed in **Optimization**. This value determines whether the model is pregenerated completely or not. To do so, the second value of **Optimization** must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.
If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if AngleStep is too small or AngleExtent too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep must be enlarged or AngleExtent must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_shape_model, AngleStep ≥ 1 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' (or 0 for backwards compatibility) is selected, create_shape_model automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_shape_model. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

---

**Parameters**

- **Template** (input_object) (multichannel-)image
  - object : byte / uint2
  - Input image whose domain will be used to create the model.

- **NumLevels** (input_control)
  - integer
  - Maximum number of pyramid levels.
  - Default value: 'auto'
  - List of values:
    - NumLevels ∈ { 'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 }

- **AngleStart** (input_control)
  - angle.rad
  - Smallest rotation of the pattern.
  - Default value: -0.39
  - Suggested values:
    - AngleStart ∈ { -3.14, -1.57, -0.79, -0.39, -0.20, 0.0 }

- **AngleExtent** (input_control)
  - angle.rad
  - Extent of the rotation angles.
  - Default value: 0.79
  - Suggested values:
    - AngleExtent ∈ { 6.29, 3.14, 1.57, 0.79, 0.39 }
  - Restriction: AngleExtent ≥ 0

- **AngleStep** (input_control)
  - angle.rad
  - Step length of the angles (resolution).
  - Default value: 'auto'
  - Suggested values:
    - AngleStep ∈ { 'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873 }
  - Restriction: AngleStep ≥ 0 & AngleStep <= pi / 16

- **Optimization** (input_control)
  - string(-array)
  - Kind of optimization and optionally method used for generating the model.
  - Default value: 'auto'
  - List of values:
    - Optimization ∈ { 'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration' }

- **Metric** (input_control)
  - string
  - Match metric.
  - Default value: 'use_polarity'
  - List of values:
    - Metric ∈ { 'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity' }

- **Contrast** (input_control)
  - number(-array)
  - Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
  - Default value: 'auto'
  - Suggested values:
    - Contrast ∈ { 'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160 }
CHAPTER 18 MATCHING

\[ \text{MinContrast} \text{ (input_control) \quad \text{number} \sim \text{integer} / \text{string}} \]
Minimum contrast of the objects in the search images.

\[ \text{Default value:} \text{ ‘auto’} \]

\[ \text{Suggested values:} \text{ MinContrast} \in \{ \text{‘auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40} \} \]

\[ \text{Restriction:} \text{ MinContrast} < \text{Contrast} \]

\[ \text{ModelID} \text{ (output_control) \quad \text{handle} \quad \text{shape_model}} \]
Handle of the model.

Matching

---

\texttt{create_shape_model_xld} ( \texttt{Contours} : \texttt{NumLevels}, \texttt{AngleStart},
\texttt{AngleExtent}, \texttt{AngleStep}, \texttt{Optimization}, \texttt{Metric},
\texttt{MinContrast} : \texttt{ModelID} )

Prepare a shape model for matching from XLD contours.

The operator \texttt{create_shape_model_xld} creates a shape model used for matching from the XLD contours passed in \texttt{Contours}. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator \texttt{create_shape_model}, which creates a shape model from a template image, the operator \texttt{create_shape_model_xld} creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter \texttt{ModelID} is a handle for this model, which is used in subsequent calls to \texttt{find_shape_model}. The center of gravity of the smallest surrounding rectangle of the \texttt{Contours} that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with \texttt{set_shape_model_origin}. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations on each level. The model can be extended by clutter parameters with \texttt{set_shape_model_clutter}.

Input parameters in detail

\textbf{NumLevels}: The number of pyramid levels is determined with the parameter \texttt{NumLevels}. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, \texttt{NumLevels} must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number
of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_shape_model_xld returns with an error message.

If NumLevels is set to 'auto', create_shape_model_xld determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_shape_model_xld determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_shape_model may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent and AngleStep: The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the object can occur in the image during the search. Note that the object can only be found in this range of angles by find_shape_model. The parameter AngleStep determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in find_shape_model, this parameter specifies the accuracy that is achievable for the angles in find_shape_model. AngleStep should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence AngleStep should be chosen larger for smaller models. If AngleExtent is not an integer multiple of AngleStep, AngleStep is modified accordingly.

To ensure that for model instances without rotation angle values of exactly 0.0 are returned by find_shape_model, the range of possible rotations is modified as follows: If there is no positive integer value n such that AngleStart plus n times AngleStep is exactly 0.0, AngleStart is decreased by up to AngleStep and AngleExtent is increased by AngleStep.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_shape_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If Optimization is set to 'auto', create_shape_model_xld automatically determines the reduction of the number of model points.

Metric: The parameter Metric determines the conditions under which the model is recognized in the image.

If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_shape_model will increase slightly in this case.

Note that the metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. This attribute is available for contours created, e.g., with edges_sub_pix with the parameter Method set to, e.g., 'canny'. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

If Metric = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of find_shape_model increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with create_shape_model_xld, and to match them simultaneously with find_shape_models.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If Metric = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of find_shape_model can also increase significantly. The metric 'ignore_color_polarity' can be used
for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as "ignore_local_polarity". It should be noted that for Metric = 'ignore_color_polarity' the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions. Note that the first two metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. For more information about contour attributes like 'edge_direction' see get_contour_attrib_xld. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

MinContrast: With MinContrast, it can be determined which contrast the object edges must at least have in the recognition performed by find_shape_model. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast should be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_shape_model.

Complete pregeneration of the model

Optionally, a second value can be passed in Optimization. This value determines whether the model is pregenerated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models',...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, find_shape_model typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if AngleStep is too small or AngleExtent too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep must be enlarged or AngleExtent must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_shape_model, AngleStep ≥ 1 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' is selected, create_shape_model_xld automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_shape_model. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

Note that, in contrast to the operator create_shape_model, it is not possible to specify a minimum size of
the model components. To avoid small model components in the shape model, short contours can be eliminated before calling create_shape_model_xld with the operator select_contours_xld.

---

**Parameters**

- **Contours** (input_object) → object
  
  Input contours that will be used to create the model.

- **NumLevels** (input_control) → integer
  
  Maximum number of pyramid levels.
  
  **Default value:** "auto"
  
  **List of values:** NumLevels ∈ {"auto", 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) → angle.rad
  
  Smallest rotation of the pattern.
  
  **Default value:** -0.39
  
  **Suggested values:** AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

- **AngleExtent** (input_control) → angle.rad
  
  Extent of the rotation angles.
  
  **Default value:** 0.79
  
  **Suggested values:** AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}
  
  **Restriction:** AngleExtent ≥ 0

- **AngleStep** (input_control) → angle.rad / string
  
  Step length of the angles (resolution).
  
  **Default value:** "auto"
  
  **Suggested values:** AngleStep ∈ {"auto", 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
  
  **Restriction:** AngleStep > 0 && AngleStep <= pi / 16

- **Optimization** (input_control) → string
  
  Kind of optimization and optionally method used for generating the model.
  
  **Default value:** "auto"
  
  **List of values:** Optimization ∈ {"auto", "none", "point_reduction_low", "point_reduction_medium", "point_reduction_high", "pregeneration", "no_pregeneration"}

- **Metric** (input_control) → string
  
  Match metric.
  
  **Default value:** "ignore_local_polarity"
  
  **List of values:** Metric ∈ {"use_polarity", "ignore_global_polarity", "ignore_local_polarity", "ignore_color_polarity"}

- **MinContrast** (input_control) → number
  
  Minimum contrast of the objects in the search images.
  
  **Default value:** 5
  
  **Suggested values:** MinContrast ∈ {1, 2, 3, 5, 7, 10, 20, 30, 40}

- **ModelID** (output_control) → shape_model
  
  Handle of the model.

---

**Result**

If the parameters are valid, the operator create_shape_model_xld returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter NumLevels is chosen such that the model contains too few points, the error 8510 is raised.

---

Module

Matching

**deserialize_shape_model** ( : : SerializedItemHandle : ModelID )

Deserializes a serialized shape model.

deserialize_shape_model deserializes a shape model, that was serialized by serialize_shape_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized shape model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created shape model with the handle ModelID.

**Parameters**

- **SerializedItemHandle** (input_control) serialized_item ~ handle
  Handle of the serialized item.
- **ModelID** (output_control) shape_model ~ handle
  Handle of the model.

**Result**

If the parameters are valid, the operator deserialize_shape_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Matching

**determine_shape_model_params** ( Template : : NumLevels,
  AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization,
  Metric, Contrast, MinContrast, Parameters : ParameterName,
  ParameterValue )

Determines the parameters of a shape model.

determine_shape_model_params determines certain parameters of a shape model automatically from the model image Template. The parameters to be determined can be specified with Parameters.
determine_shape_model_params can be used to determine the same parameters that are determined automatically when the respective parameter in create_shape_model, create_scaled_shape_model, or create_aniso_shape_model is set to 'auto': the number of pyramid levels (Parameters = 'num_levels'), the angle step length (Parameters = 'angle_step'), the scale step length (Parameters = 'scale_step' for isotropic scaling and 'scale_r_step' and/or 'scale_c_step' for anisotropic scaling), the kind of optimization (Parameters = 'optimization'), the threshold (Parameters = 'contrast') or the hysteresis thresholds (Parameters = 'contrast_hyst') for the contrast, the minimum size of the object parts (Parameters = 'min_size'), and the minimum contrast (Parameters = 'min_contrast'). By passing a tuple of the above values in Parameters, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed. In this case both hysteresis thresholds are determined, i.e., the operator behaves like passing 'contrast_hyst' instead of 'contrast'.

determine_shape_model_params is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in ParameterName and ParameterValue. The parameter names in ParameterName are identical to the names in Parameters, where, of course, the value 'all' is replaced by the actual parameter names. An exception is the parameter 'contrast_hyst', for which the two values 'contrast_low' and 'contrast_high' are returned.

The remaining parameters (NumLevels, AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization, Metric, Contrast, and MinContrast) have the same meaning as in create_shape_model, create_scaled_shape_model, and create_aniso_shape_model. The description of these parameters can be looked up with these operators. These parameters are used by determine_shape_model_params to calculate the parameters to be determined in the same manner as in create_shape_model, create_scaled_shape_model, and create_aniso_shape_model.

It should be noted that if the parameters of a shape model with isotropic scaling should be determined, i.e., if Parameters contains 'scale_step' either explicitly or implicitly via 'all', the parameters ScaleMin and ScaleMax must contain one value each. If the parameters of a shape model with anisotropic scaling should be determined, i.e., if Parameters contains 'scale_r_step' or 'scale_c_step' either explicitly or implicitly, the parameters ScaleMin and ScaleMax must contain two values each. In this case, the first value of the respective parameter refers to the scaling in the row direction, while the second value refers to the scaling in the column direction.

Note that in determine_shape_model_params some parameters appear that can also be determined automatically (NumLevels, Optimization, Contrast, MinContrast). If these parameters should not be determined automatically, i.e., their name is not passed in Parameters, the corresponding parameters must contain valid values and must not be set to 'auto'. In contrast, if these parameters are to be determined automatically, their values are treated in the following way: If the optimization or the (hysteresis) contrast is to be determined automatically, i.e., Parameters contains the value 'optimization' or 'contrast' ('contrast_hyst'), the values passed in Optimization and Contrast are ignored. In contrast, if the maximum number of pyramid levels or the minimum contrast is to be determined automatically, i.e., Parameters contains the value 'num_levels' or 'min_contrast', you can let HALCON determine suitable values and at the same time specify an upper or lower boundary, respectively:

If the maximum number of pyramid levels should be specified in advance, NumLevels can be set to the particular value. If in this case Parameters contains the value 'num_levels', the computed number of pyramid levels is at most NumLevels. If NumLevels is set to 'auto' (or 0 for backwards compatibility), the number of pyramid levels is determined without restrictions as large as possible.

If the minimum contrast should be specified in advance, MinContrast can be set to the particular value. If in this case Parameters contains the value 'min_contrast', the computed minimum contrast is at least MinContrast. If MinContrast is set to 'auto', the minimum contrast is determined without restrictions.

Attention

In some cases, the maximum number of pyramid levels that is returned by determine_shape_model_params is higher than the number of levels that are actually used in the shape model. The latter can be queried by using get_shape_model_params after creating the model. This might happen if the model is created by using create_scaled_shape_model or create_aniso_shape_model and ScaleMin, ScaleRMin, or ScaleCMin is below 1.0.
Parameters

- **Template** (input_object) .......................................................... (multichannel-)image  \sim object: byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) .................................................. integer  \sim integer / string
  Maximum number of pyramid levels.
  Default value: ‘auto’
  List of values: NumLevels \in \{ ‘auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \}

- **AngleStart** (input_control) ................................................. angle / rad
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: AngleStart \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0 \}

- **AngleExtent** (input_control) .............................................. angle / rad
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent \in \{ 6.29, 3.14, 1.57, 0.79, 0.39 \}
  Restriction: AngleExtent \geq 0

- **ScaleMin** (input_control) ................................................... number / array
  Minimum scale of the model.
  Default value: 0.9
  Suggested values: ScaleMin \in \{ 0.5, 0.6, 0.7, 0.8, 0.9, 1.0 \}
  Restriction: ScaleMin > 0

- **ScaleMax** (input_control) ................................................... number / array
  Maximum scale of the model.
  Default value: 1.1
  Suggested values: ScaleMax \in \{ 1.0, 1.1, 1.2, 1.3, 1.4, 1.5 \}
  Restriction: ScaleMax \geq ScaleMin

- **Optimization** (input_control) .............................................. string
  Kind of optimization.
  Default value: ‘auto’
  List of values: Optimization \in \{ ‘auto’, ‘none’, ‘point_reduction_low’, ‘point_reduction_medium’,
  ‘point_reduction_high’ \}

- **Metric** (input_control) ..................................................... string
  Match metric.
  Default value: ‘use_polarity’
  List of values: Metric \in \{ ‘use_polarity’, ‘ignore_global_polarity’, ‘ignore_local_polarity’,
  ‘ignore_color_polarity’ \}

- **Contrast** (input_control) ................................................. number / array
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum
  size of the object parts.
  Default value: ‘auto’
  Suggested values: Contrast \in \{ ‘auto’, ‘auto_contrast’, ‘auto_contrast_hyst’, ‘auto_min_size’, 10, 20, 30,
  40, 60, 80, 100, 120, 140, 160 \}

- **MinContrast** (input_control) ............................................. integer
  Minimum contrast of the objects in the search images.
  Default value: ‘auto’
  Suggested values: MinContrast \in \{ ‘auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40 \}
  Restriction: MinContrast < Contrast

- **Parameters** (input_control) ...............................................
  Parameters to be determined automatically.
  Default value: ‘all’

- **ParameterName** (output_control) ...........................................
  Name of the automatically determined parameter.

- **ParameterValue** (output_control) ....................................... number / array
  Value of the automatically determined parameter.
Result

If the parameters are valid, the operator determine_shape_model_params returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters NumLevels and Contrast are chosen such that the model contains too few points, or the input image does not contain a sufficient number of significant features, the error 8510 is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

find_aniso_shape_model ( Image : , ModelID, AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, ScaleR, ScaleC, Score )

Find the best matches of an anisotropically scaled shape model in an image.

The operator find_aniso_shape_model finds the best NumMatches instances of the anisotropically scaled shape model ModelID in the input image Image. The model must have been created previously by calling create_aniso_shape_model or read_shape_model.

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in Row, Column, Angle, ScaleR, and ScaleC. Additionally, the score of each found instance is returned in Score.

Input parameters in detail

The image and its domain: The domain of the image Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with create_aniso_shape_model. A different origin set with set_shape_model_origin is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that, if for certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels} - 1}$. This behavior can be changed with set_system('border_shape_models','true') for all models or with set_shape_model_param(ModelID, 'border_shape_models','true') for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than MinScore. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels} - 1}$ using, e.g., dilation_circle.

AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax: The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. The parameters...
MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

In case that the shape model has been extended by clutter parameters with set_shape_model_clutter and thus ‘use_clutter’ is enabled, MinScore expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using set_shape_model_clutter, NumMatches also considers the second value passed in MinScore: If more than NumMatches instances with a score greater than the first entry of MinScore and a clutter value smaller than the second entry of MinScore are found in the image, only the best NumMatches instances with respect to clutter are returned. Still, MinScore takes precedence over NumMatches and NumMatches must be set to 0 if all model instances fulfilling the conditions imposed by MinScore should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

SubPixel: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to ‘none’ (or ‘false’ for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with create_aniso_shape_model. If SubPixel is set to ‘interpolation’ (or ‘true’) the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high...
NumLevels: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_aniso_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_aniso_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_aniso_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_aniso_shape_model. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least ‘least_squares’. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or
deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in NumLevels. If, e.g., NumLevels is set to \([4,-2]\), the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

_Greediness:_ The parameter _Greediness_ determines how “greedily” the search should be carried out. If _Greediness_ = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If _Greediness_ = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For _Greediness_ = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for _Greediness_ = 0.9.

**Output parameters in detail**

_\textbf{Row, Column, Angle, ScaleR, ScaleC}:_ The position, rotation, and scale in the row and column direction of the found instances of the model are returned in _Row, Column, Angle, ScaleR, and ScaleC_. The coordinates _Row_ and _Column_ are related to the position of the origin of the shape model in the search image. However, _Row_ and _Column_ do not exactly correspond to this position. Instead, _find_aniso_shape_model_ returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see _affine_trans_pixel_). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with _create_aniso_shape_model_. A different origin can be set with _set_shape_model_origin_.

_\textbf{Score}:_ The score of each found instance is returned in _Score_. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using _set_shape_model_clutter_, following the above values _Score_ also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, _Score_ = \([0.9, 0.8, 0.2, 0.1]\) is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Specifying a timeout**

Using the operator _set_shape_model_param_ you can specify a ‘timeout’ for _find_aniso_shape_model_. If _find_aniso_shape_model_ reaches this ‘timeout’, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling ranges specified by _ScaleRMin, ScaleRMax, ScaleCMin, and ScaleCMax_, _find_aniso_shape_model_ needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of _find_aniso_shape_model_ exceeds the value of the specified ‘timeout’ by this time.

**Visualization of the results**

To display the results found by shape-based matching, we highly recommend the usage of the procedure _dev_display_shape_matching_results_.

**Further Information**

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter _Transformations / 2D Transformations_.

Parameters

- **Image** (input_object) ..........................(multichannel-)image \( \sim \) object : byte / uint2
  Input image in which the model should be found.

- **ModelID** (input_control) ......................... shape_model \( \sim \) handle
  Handle of the model.

- **AngleStart** (input_control) ...................... angle.rad \( \sim \) real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: \( \text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\} \)

- **AngleExtent** (input_control) .................... angle.rad \( \sim \) real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: \( \text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\} \)
  Restriction: \( \text{AngleExtent} \geq 0 \)

- **ScaleRMin** (input_control) ...................... number \( \sim \) real
  Minimum scale of the model in the row direction.
  Default value: 0.9
  Suggested values: \( \text{ScaleRMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  Restriction: \( \text{ScaleRMin} > 0 \)

- **ScaleRMax** (input_control) ...................... number \( \sim \) real
  Maximum scale of the model in the row direction.
  Default value: 1.1
  Suggested values: \( \text{ScaleRMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\} \)
  Restriction: \( \text{ScaleRMax} \geq \text{ScaleRMin} \)

- **ScaleCMin** (input_control) ...................... number \( \sim \) real
  Minimum scale of the model in the column direction.
  Default value: 0.9
  Suggested values: \( \text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  Restriction: \( \text{ScaleCMin} > 0 \)

- **ScaleCMax** (input_control) ...................... number \( \sim \) real
  Maximum scale of the model in the column direction.
  Default value: 1.1
  Suggested values: \( \text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\} \)
  Restriction: \( \text{ScaleCMax} \geq \text{ScaleCMin} \)

- **MinScore** (input_control) ....................... real(-array) \( \sim \) real
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: \( \text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  Typical range of values: \( 0 \leq \text{MinScore} \leq 1 \)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) .................... integer \( \sim \) integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: \( \text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\} \)

- **MaxOverlap** (input_control) .................... real \( \sim \) real
  Maximum overlap of the instances of the model to be found.
  Default value: 0.5
  Suggested values: \( \text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  Typical range of values: \( 0 \leq \text{MaxOverlap} \leq 1 \)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **SubPixel** (input_control) ....................... string(-array) \( \sim \) string
  Subpixel accuracy if not equal to ‘none’.
  Default value: ‘least_squares’
  Suggested values: \( \text{SubPixel} \in \{\text{none}, \text{interpolation}, \text{least_squares}, \text{least_squares_high}, \text{least_squares_very_high}, \text{max_deformation 1}, \text{max_deformation 2}, \text{max_deformation 3}, \text{max_deformation 4}, \text{max_deformation 5}, \text{max_deformation 6}\} \)
CHAPTER 18 MATCHING

- **NumLevels** (input_control) .................................................. integer-array \(\sim\) integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).
  Default value: 0
  List of values: \(\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}\)

- **Greediness** (input_control) ................................................... real \(\sim\) real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: \(\text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{Greediness} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **Row** (output_control) ....................................................... point.y-array \(\sim\) real
  Row coordinate of the found instances of the model.

- **Column** (output_control) .................................................... point.x-array \(\sim\) real
  Column coordinate of the found instances of the model.

- **Angle** (output_control) ..................................................... angle.rad-array \(\sim\) real
  Rotation angle of the found instances of the model.

- **ScaleR** (output_control) .................................................... number-array \(\sim\) real
  Scale of the found instances of the model in the row direction.

- **ScaleC** (output_control) .................................................... number-array \(\sim\) real
  Scale of the found instances of the model in the column direction.

- **Score** (output_control) ..................................................... real-array \(\sim\) real
  Score of the found instances of the model.

Example

```cpp
create_aniso_shape_model (ImageReduced, 0, rad(-15), rad(30), 0, \
  0.9, 1.1, 0, 0.9, 1.1, 0, 'none', \
  'use_polarity', 30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_aniso_shape_model (SearchImage, ModelID, rad(-15), rad(30), \
  0.9, 1.1, 0.9, 1.1, 0.5, 1, 0.5, 'interpolation', \
  0, 0, Row, Column, Angle, ScaleR, ScaleC, Score)
* Create transformation matrix
  hom_mat2d_identity (HomMat2DIdentity)
  hom_mat2d_scale (HomMat2DIdentity, ScaleR, ScaleC, 0, 0, HomMat2DScale)
  hom_mat2d_rotate (HomMat2DScale, Angle, 0, 0, HomMat2DRotate)
  hom_mat2d_translate (HomMat2DRotate, Row, Column, HomMat2DObject)
* Calculate true position of the model origin in the search image
  affine_trans_pixel (HomMat2DObject, 0, 0, RowObject, ColObject)
* Display results
  dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \
    ScaleR, ScaleC, 0)
```

Result

If the parameter values are correct, the operator `find_aniso_shape_model` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system (L'_no_object_result', <Result>). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

- `create_aniso_shape_model`
- `read_shape_model`
- `set_shape_model_origin`
- `set_shape_model_clutter`

Find the best matches of multiple anisotropically scaled shape models.

The operator `find_aniso_shape_models` finds the best `NumMatches` instances of the anisotropically scaled shape models that are passed in `ModelIDs` in the input image `Image`. The models must have been created previously by calling `create_aniso_shape_model` or `read_shape_model`. In contrast to `find_aniso_shape_model`, multiple models can be searched in the same image in one call.

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. The score of each found instance is returned in `Score`. The type of the found instances of the models is returned in `Model`. For details see respective sections below.

Characteristics of the parameter semantics

Compared to `find_aniso_shape_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. (`NumLevels` may also contain either two or twice the number of elements as `ModelIDs`.) More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_aniso_shape_models` with multiple values for `ModelIDs`, `NumMatches` and `MaxOverlap` has the same effect as multiple independent calls to `find_aniso_shape_model` with the respective parameters. However, a single call to `find_aniso_shape_models` is considerably more efficient.

Input parameters in detail

The image and its domain: The domain of the `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models','true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models','true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

As usual, the domain of the input `Image` is used to restrict the search space for the reference point of the models `ModelIDs`. Consistent with the above semantics, the input `Image` can therefore contain a single image object or an image object tuple containing multiple image objects. If `Image` contains a single image object `O`, its domain is the same as the domain of `O` itself.
object, its domain is used as the region of interest for all models in ModelIDs. If Image contains multiple image objects, each domain is used as the region of interest for the corresponding model in ModelIDs. In this case, the images have to be identical except for their domains, i.e., Image cannot be constructed in an arbitrary manner using concat_obj, but must be created from the same image using add_channels or equivalent calls. If this is not the case, an error message is returned.

AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax: The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. The parameters ScaleRMin, ScaleRMax, ScaleCMin, and ScaleCMax determine the range of scales in the row and column directions for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with create_aniso_shape_model. In particular, this means that the angle ranges of the model and the search must overlap.

If in ModelIDs a model is passed that was created by using create_shape_model or create_scaled_shape_model then the model is searched with an isotropic scaling of 1.0 or with an isotropic scaling within the range from ScaleRMin to ScaleRMax, respectively. In this case, for ScaleR and ScaleC identical values are returned.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. AngleStart and AngleExtent as well as ScaleRMin/ScaleCMin and ScaleRMax/ScaleCMax are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

If a single value is passed in MinScore, this value is applied to found instances of all models. If, on the other hand, MinScore contains multiple values, the values are applied separately for the respective model.

In case that the shape models have been extended by clutter parameters with set_shape_model_clutter and thus 'use_clutter' is enabled, MinScore expects for each minimum score an additional value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for 'use_clutter'.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, MinScore must contain twice the number of elements as ModelIDs.
In this case, the minimum score and the maximum clutter must be specified interleaved in MinScore. If, for example, two models are specified in ModelIDs, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, MinScore = [0.9, 0.8, 0.1, 0.2] must be selected.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.
If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using set_shape_model_clutter, NumMatches also considers the second value passed in MinScore: If more than NumMatches instances with a score greater than the first entry of MinScore and a clutter value smaller than the second entry of MinScore are found in the image, only the best NumMatches instances with respect to clutter are returned. Still, MinScore takes precedence over NumMatches and NumMatches must be set to 0 if all model instances fulfilling the conditions imposed by MinScore...
should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0.

If NumMatches contains one element, find_aniso_shape_models returns the best NumMatches instances of the model irrespective of the type of the model. If, for example, two models are passed in ModelIDs and NumMatches = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, NumMatches contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in NumMatches. If, for example, NumMatches = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned. If a single value is passed in MaxOverlap, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in MaxOverlap, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

SubPixel: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to ‘none’ (or ‘false’ for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with create_aniso_shape_model. If SubPixel is set to ‘interpolation’ (or ‘true’) the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to ‘interpolation’, this mode requires additional computation time. The different modes for least-squares adjustment (‘least_squares’, ‘least_squares_high’, and ‘least_squares_very_high’) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to ‘interpolation’. If least-squares adjustment is desired, ‘least_squares’ should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value ‘max_deformation’ followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value ‘max_deformation 2’ must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value ‘max_deformation 0’ corresponds to a search without allowing deformations, i.e., the behavior is the same as if no ‘max_deformation’ is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if ‘max_deformation’ and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either ‘max_deformation’ or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the
subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment. If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in ModelIDs exactly one value for the subpixel extraction must be passed in SubPixel. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in ModelIDs and for the first model the subpixel extraction is set to 'interpolation' and no object deformations are allowed and for the second model the subpixel extraction is set to 'least_squares' and a maximum object deformation of 3 pixels is allowed, then the tuple ['interpolation', 'least_squares', 'max_deformation 3'] may be passed in SubPixel. Alternatively, the equivalent tuple ['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3'] may be passed.

**NumLevels:** The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_aniso_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_aniso_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_aniso_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_aniso_shape_models. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least 'least_squares'. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, NumLevels must contain twice the number of elements as ModelIDs. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in NumLevels. If, for example, two models are specified in ModelIDs, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, NumLevels = [5, 2, 4, 1] must be selected. If exactly two models are specified in ModelIDs, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in NumLevels is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in NumLevels. If, e.g., NumLevels is set to [5,2,4,-1], the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this
model. For the second shape model, the lowest pyramid level is set to -1. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

**Greediness:** The parameter **Greediness** determines how “greedily” the search should be carried out. If **Greediness** = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If **Greediness** = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For **Greediness** = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for **Greediness** = 0.9.

### Output parameters in detail

**Row, Column, Angle, ScaleR, ScaleC:** The position, rotation, and scale in the row and column direction of the found instances of the model are returned in **Row, Column, Angle, ScaleR, and ScaleC.** The coordinates **Row** and **Column** are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin can be set with `set_shape_model_origin`.

Note that the coordinates **Row** and **Column** do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_aniso_shape_model` shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure `dev_display_shape_matching_results` can be used.

**Score:** The score of each found instance is returned in **Score.** The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, following the above values **Score** also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, **Score** = [0.9, 0.8, 0.2, 0.1] is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Model:** The type of the found instances of the models is returned in **Model.** The elements of **Model** are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to `|ModelIDs| - 1`. Hence, a value of 0 in an element of **Model** corresponds to an instance of the first model in `ModelIDs`.

### Specifying a timeout

Using the operator `set_shape_model_param` you can specify a ‘timeout’ for `find_aniso_shape_models`. If the shape models referenced by `ModelIDs` hold different values for ‘timeout’, `find_aniso_shape_models` uses the smallest one. If `find_aniso_shape_models` reaches this ‘timeout’, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling ranges specified by `ScaleRMin`, `ScaleRMax`, `ScaleCMin` and `ScaleCMax`, `find_aniso_shape_models` needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of `find_aniso_shape_models` exceeds the value of the specified ‘timeout’ by this time.

**MinContrast with multiple models**

Please note, that the different models that are given with the parameter `ModelIDs` should have been created with the same value of `MinContrast`. If they were created with different values for `MinContrast`, `find_aniso_shape_models` will use the smallest of these values.

### Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

### Further Information
For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

**Parameters**

- **Image** (input_object) \(\text{object : byte / uint2}\)
  - Input image in which the models should be found.

- **ModelIDs** (input_control) \(\text{shape_model(-array)} \sim \text{handle}\)
  - Handle of the models.

- **AngleStart** (input_control) \(\text{angle.rad(-array)} \sim \text{real}\)
  - Smallest rotation of the models.
    - Default value: -0.39
    - Suggested values: \(\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)

- **AngleExtent** (input_control) \(\text{angle.rad(-array)} \sim \text{real}\)
  - Extent of the rotation angles.
    - Default value: 0.79
    - Suggested values: \(\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)
    - Restriction: \(\text{AngleExtent} \geq 0\)

- **ScaleRMin** (input_control) \(\text{number(-array)} \sim \text{real}\)
  - Minimum scale of the models in the row direction.
    - Default value: 0.9
    - Suggested values: \(\text{ScaleRMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
    - Restriction: \(\text{ScaleRMin} > 0\)

- **ScaleRMax** (input_control) \(\text{number(-array)} \sim \text{real}\)
  - Maximum scale of the models in the row direction.
    - Default value: 1.1
    - Suggested values: \(\text{ScaleRMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)
    - Restriction: \(\text{ScaleRMax} \geq \text{ScaleRMin}\)

- **ScaleCMin** (input_control) \(\text{number(-array)} \sim \text{real}\)
  - Minimum scale of the models in the column direction.
    - Default value: 0.9
    - Suggested values: \(\text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
    - Restriction: \(\text{ScaleCMin} > 0\)

- **ScaleCMax** (input_control) \(\text{number(-array)} \sim \text{real}\)
  - Maximum scale of the models in the column direction.
    - Default value: 1.1
    - Suggested values: \(\text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)
    - Restriction: \(\text{ScaleCMax} \geq \text{ScaleCMin}\)

- **MinScore** (input_control) \(\text{real(-array)} \sim \text{real}\)
  - Minimum score of the instances of the models to be found.
    - Default value: 0.5
    - Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
    - Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
    - Minimum increment: 0.01
    - Recommended increment: 0.05

- **NumMatches** (input_control) \(\text{integer(-array)} \sim \text{integer}\)
  - Number of instances of the models to be found (or 0 for all matches).
    - Default value: 1
    - Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)

- **MaxOverlap** (input_control) \(\text{real(-array)} \sim \text{real}\)
  - Maximum overlap of the instances of the models to be found.
    - Default value: 0.5
    - Suggested values: \(\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
    - Typical range of values: \(0 \leq \text{MaxOverlap} \leq 1\)
    - Minimum increment: 0.01
    - Recommended increment: 0.05
18.5. SHAPE-BASED

SubPixel (input_control) .................................................. string(-array) ~ string
Subpixel accuracy if not equal to 'none'.

Default value: 'least_squares'
Suggested values: SubPixel ∈ {'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}

NumLevels (input_control) .............................................. integer(-array) ~ integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).

Default value: 0
List of values: NumLevels ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

Greediness (input_control) ............................................. real(-array) ~ real
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).

Default value: 0.9
Suggested values: Greediness ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Typical range of values: 0 ≤ Greediness ≤ 1
Minimum increment: 0.01
Recommended increment: 0.05

Row (output_control) ..................................................... point.y-array ~ real
Row coordinate of the found instances of the models.

Column (output_control) ................................................ point.x-array ~ real
Column coordinate of the found instances of the models.

Angle (output_control) ................................................... angle.rad-array ~ real
Rotation angle of the found instances of the models.

ScaleR (output_control) .................................................. number-array ~ real
Scale of the found instances of the models in the row direction.

ScaleC (output_control) .................................................. number-array ~ real
Scale of the found instances of the models in the column direction.

Score (output_control) ................................................... real-array ~ real
Score of the found instances of the models.

Model (output_control) .................................................. integer-array ~ integer
Index of the found instances of the models.

Example

read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_aniso_shape_model (ImageReduced1,'auto', -0.39, 0.79, 'auto', 0.9, \1.1, 'auto', 0.9, 1.1, 'auto', 'auto', 'auto', ModelID1)
create_aniso_shape_model (ImageReduced2,'auto', -0.39, 0.79, 'auto', 0.9, \1.1, 'auto', 0.9, 1.1, 'auto', 'auto', 'auto', ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_aniso_shape_models(Image, ModelIDs, -0.39, 0.79, 0.9, 1.1, 0.9, 1.1, \0.5, 1, 0.5, 'least_squares', 0, 0.9, Row, Column, \Angle, ScaleR, ScaleC, Score, Model)

* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, \ScaleR, ScaleC, Model)

Result
If the parameter values are correct, the operator find_aniso_shape_models returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Module

find_scaled_shape_model ( Image : : ModelID, AngleStart,
  AngleExtent, ScaleMin, ScaleMax, MinScore, NumMatches,
  MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column,
  Angle, Scale, Score )

Find the best matches of an isotropically scaled shape model in an image.
The operator find_scaled_shape_model finds the best NumMatches instances of the isotropically scaled
shape model ModelID in the input image Image. The model must have been created previously by calling
create_scaled_shape_model or read_shape_model.
The position, rotation, and scale of the found instances of the model are returned in Row, Column, Angle,
and Scale. The score of each found instance is returned in Score.

Input parameters in detail

The image and its domain: The domain of the image Image determines the search space for the refer-
cence point of the model, i.e., for the center of gravity of the domain (region) of the image that was
used to create the shape model with create_scaled_shape_model. A different origin set with
set_shape_model_origin is not taken into account. The model is searched within those points of
the domain of the image, in which the model lies completely within the image. This means that the
model will not be found if it extends beyond the borders of the image, even if it would achieve a score
greater than MinScore (see below). Note that, if for a certain pyramid level the model touches the image
border, it might not be found even if it lies completely within the original image. As a rule of thumb,
the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This be-
havior can be changed with set_system('border_shape_models', 'true') for all models or
with set_shape_model_param(ModelID, 'border_shape_models', 'true') for a specific
model, which will cause models that extend beyond the image border to be found if they achieve a score
greater than MinScore. Here, points lying outside the image are regarded as being occluded, i.e., they
lower the score. It should be noted that the runtime of the search will increase in this mode. Note further,
that in rare cases, which occur typically only for artificial images, the model might not be found also if for
certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the
reduced domain by $2^{NumLevels-1}$ using, e.g., dilation_circle.

AngleStart, AngleExtent, ScaleMin, ScaleMax: The parameters AngleStart and AngleExtent determine the
range of rotations for which the model is searched. The parameters ScaleMin and ScaleMax deter-
mine the range of scales for which the model is searched. If necessary, both ranges are clipped to the range
given when the model was created with create_scaled_shape_model. In particular, this means that
the angle ranges of the model and the search must overlap.
Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found.
This may happen if the specified range is smaller than the range given during the creation of the model.
AngleStart and AngleExtent as well as ScaleMin and ScaleMax are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

In case that the shape model has been extended by clutter parameters with set_shape_model_clutter and thus 'use_clutter' is enabled, MinScore expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using set_shape_model_clutter, NumMatches also considers the second value passed in MinScore: If more than NumMatches instances with a score greater than the first entry of MinScore and a clutter value smaller than the second entry of MinScore are found in the image, only the best NumMatches instances with respect to clutter are returned. Still, MinScore takes precedence over NumMatches and NumMatches must be set to 0 if all model instances fulfilling the conditions imposed by MinScore should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different orientations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

SubPixel: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with create_scaled_shape_model. If SubPixel is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are only slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object
The number of pyramid levels used during the search is determined with \texttt{NumLevels}. This can be done by passing the optional parameter value \texttt{max\_deformation} followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value \texttt{max\_deformation 2} must be passed in \texttt{SubPixel} in addition to the above described mode for the subpixel extraction, i.e., for example \texttt{[least\_squares, max\_deformation 2]}. Passing the value \texttt{max\_deformation 0} corresponds to a search without allowing deformations, i.e., the behavior is the same as if no \texttt{max\_deformation} is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if \texttt{max\_deformation} and \texttt{AngleExtent} are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either \texttt{max\_deformation} or \texttt{AngleExtent} to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if \texttt{least\_squares}, \texttt{least\_squares\_high}, or \texttt{least\_squares\_very\_high} (see above) is chosen for the subpixel extraction (in comparison to \texttt{none} or \texttt{interpolation}). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

\textbf{NumLevels:} The number of pyramid levels used during the search is determined with \texttt{NumLevels}. If necessary, the number of levels is clipped to the range given when the shape model was created with \texttt{create\_scaled\_shape\_model}. If \texttt{NumLevels} is set to 0, the number of pyramid levels specified in \texttt{create\_scaled\_shape\_model} is used. In certain cases, the number of pyramid levels that was determined automatically with, for example, \texttt{create\_scaled\_shape\_model} may be too high. The consequence may be that some matches may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting \texttt{MinScore} to a very low value to find all matches, it may be better to query the value of \texttt{NumLevels} with \texttt{get\_shape\_model\_params} and then use a slightly lower value in \texttt{find\_scaled\_shape\_model}. This approach is often better regarding the speed and robustness of the matching.

Optionally, \texttt{NumLevels} can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of \texttt{[4,2]} for \texttt{NumLevels} means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, \texttt{SubPixel} should be set to at least \texttt{least\_squares}. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in \texttt{NumLevels}. If, e.g., \texttt{NumLevels} is set to \texttt{[4,-2]}, the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid
level will then be returned.

**Greediness:** The parameter *Greediness* determines how “greedily” the search should be carried out. If *Greediness* = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If *Greediness* = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For *Greediness* = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for *Greediness* = 0.9.

### Output parameters in detail

**Row, Column, Angle and Scale:** The position, rotation, and scale of the found instances of the model are returned in *Row*, *Column*, *Angle*, and *Scale*. The coordinates *Row* and *Column* are related to the position of the origin of the shape model in the search image. However, *Row* and *Column* do not exactly correspond to this position. Instead, *find_scaled_shape_model* returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see *affine_trans_pixel*). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with *create_shape_model*. A different origin can be set with *set_shape_model_origin*.

**Score:** The score of each found instance is returned in *Score*. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using *set_shape_model_clutter*, following the above values *Score* also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, *Score* = [0.9, 0.8, 0.2, 0.1] is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

### Specifying a timeout

Using the operator *set_shape_model_param* you can specify a ‘timeout’ for *find_scaled_shape_model*. If *find_scaled_shape_model* reaches this ‘timeout’, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling range specified by *ScaleMin*, and *ScaleMax*, *find_scaled_shape_model* needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of *find_scaled_shape_model* exceeds the value of the specified ‘timeout’ by this time.

### Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure *dev_display_shape_matching_results*.

### Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

---

**Parameters**

- **Image** *(input_object) ..............................................(multichannel-)image ∼ object : byte / uint2*
  
  Input image in which the model should be found.

- **ModelID** *(input_control) .............................................. shape_model ∼ handle*
  
  Handle of the model.

- **AngleStart** *(input_control) .............................................. angle.rad ∼ real*
  
  Smallest rotation of the model.

  Default value: -0.39

  Suggested values: AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]
CHAPTER 18 MATCHING

- **AngleExtent** (input_control) .............................................................. angle.rad $\sim$ real
  Extent of the rotation angles.
  Default value: 0.78
  Suggested values: $\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
  Restriction: $\text{AngleExtent} \geq 0$

- **ScaleMin** (input_control) ................................................................. number $\sim$ real
  Minimum scale of the model.
  Default value: 0.9
  Suggested values: $\text{ScaleMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Restriction: $\text{ScaleMin} > 0$

- **ScaleMax** (input_control) ................................................................. number $\sim$ real
  Maximum scale of the model.
  Default value: 1.1
  Suggested values: $\text{ScaleMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
  Restriction: $\text{ScaleMax} \geq \text{ScaleMin}$

- **MinScore** (input_control) ................................................................. real(-array) $\sim$ real
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: $\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{MinScore} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) ............................................................ integer $\sim$ integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: $\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}$

- **MaxOverlap** (input_control) ............................................................. real $\sim$ real
  Maximum overlap of the instances of the model to be found.
  Default value: 0.5
  Suggested values: $\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{MaxOverlap} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **SubPixel** (input_control) ................................................................. string(-array) $\sim$ string
  Subpixel accuracy if not equal to ‘none’.
  Default value: ‘least_squares’

- **NumLevels** (input_control) ............................................................. integer(-array) $\sim$ integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if $|\text{NumLevels}| = 2$).
  Default value: 0
  List of values: $\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- **Greediness** (input_control) ............................................................. real $\sim$ real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: $\text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{Greediness} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **Row** (output_control) ................................................................. point.y-array $\sim$ real
  Row coordinate of the found instances of the model.

- **Column** (output_control) ............................................................. point.x-array $\sim$ real
  Column coordinate of the found instances of the model.

- **Angle** (output_control) ............................................................... angle.rad-array $\sim$ real
  Rotation angle of the found instances of the model.

- **Scale** (output_control) ............................................................... number-array $\sim$ real
  Scale of the found instances of the model.

> **Score** (output_control) ..........................................................real-array \(\rightarrow\) real

Score of the found instances of the model.

---

**Example**

```c
create_scaled_shape_model (ImageReduced, 0, rad(-45), rad(180), 0, \
  0.9, 1.1, 0, 'none', 'use_polarity', \
  30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_scaled_shape_model (SearchImage, ModelID, rad(-45), rad(180), \
  0.9, 1.1, 0.5, 1, 0.5, 'interpolation', \
  0, 0, Row, Column, Angle, Scale, Score)
* Create transformation matrix
  vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2DTmp)
  hom_mat2d_scale (HomMat2DTmp, Scale, Scale, Row, Column, HomMat2DObject)
  * Calculate true position of the model origin in the search image
    affine_trans_pixel (HomMat2DObject, 0, 0, RowObject, ColObject)
  * Display results
    dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \
      Scale, 1, 0)
```

---

**Result**

If the parameter values are correct, the operator **find_scaled_shape_model** returns the value \(2 \ (H\_MSG\_TRUE)\). If the input is empty (no input images are available) the behavior can be set via **set_system** ('no_object_result',<Result>). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Matching

---

**find_scaled_shape_models** ( Image : : ModelIDs, AngleStart, 
  AngleExtent, ScaleMin, ScaleMax, MinScore, NumMatches, 
  MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, 
  Angle, Scale, Score, Model )

Find the best matches of multiple isotropically scaled shape models.

The operator **find_scaled_shape_models** finds the best **NumMatches** instances of the isotropically scaled shape models that are passed in **ModelIDs** in the input image **Image**. The models must have been
created previously by calling `create_scaled_shape_model` or `read_shape_model`. In contrast to `find_scaled_shape_model`, multiple models can be searched in the same image in one call.

The position, rotation, and scale of the found instances of the model are returned in `Row`, `Column`, `Angle`, and `Scale`. The score of each found instance is returned in `Score`. The type of the found instances of the models is returned in `Model`. For details see respective sections below.

**Characteristics of the parameter semantics**

Compared to `find_scaled_shape_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. (`NumLevels` may also contain either two or twice the number of elements as `ModelIDs`.) More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_scaled_shape_models` with multiple values for `ModelIDs.NumMatches` and `MaxOverlap` has the same effect as multiple independent calls to `find_scaled_shape_model` with the respective parameters. However, a single call to `find_scaled_shape_models` is considerably more efficient.

**Input parameters in detail**

**The image and its domain:** The domain of the `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_scaled_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with `set_system('border_shape_models','true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models','true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., `dilation_circle`.

As usual, the domain of the input `Image` is used to restrict the search space for the reference point of the models `ModelIDs`. Consistent with the above semantics, the input `Image` can therefore contain a single image object or an image object tuple containing multiple image objects. If `Image` contains a single image object, its domain is used as the region of interest for all models in `ModelIDs`. If `Image` contains multiple image objects, each domain is used as the region of interest for the corresponding model in `ModelIDs`. In this case, the images have to be identical except for their domains, i.e., `Image` cannot be constructed in an arbitrary manner using `concat_obj`, but must be created from the same image using `add_channels` or equivalent calls. If this is not the case, an error message is returned.

**AngleStart, AngleExtent, ScaleMin, ScaleMax:** The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. The parameters `ScaleMin` and `ScaleMax` determine the range of scales for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with `create_scaled_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` as well as `ScaleMin` and `ScaleMax` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

**MinScore:** The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.
If a single value is passed in \texttt{MinScore}, this value is applied to found instances of all models. If, on the other hand, \texttt{MinScore} contains multiple values, the values are applied separately for the respective model.

In case that the shape models have been extended by clutter parameters with \texttt{set_shape_model_clutter} and thus 'use_clutter' is enabled, \texttt{MinScore} expects for each minimum score an additional value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for 'use_clutter'.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, \texttt{MinScore} must contain twice the number of elements as ModelIDs. In this case, the minimum score and the maximum clutter must be specified interleaved in \texttt{MinScore}. If, for example, two models are specified in ModelIDs, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, \texttt{MinScore} = \{0.9, 0.1, 0.8, 0.2\} must be selected.

\textbf{NumMatches:} The maximum number of instances to be found can be determined with \texttt{NumMatches}. If more than \texttt{NumMatches} instances with a score greater than \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances are returned. If fewer than \texttt{NumMatches} are found, only that number is returned, i.e., the parameter \texttt{MinScore} takes precedence over \texttt{NumMatches}. If all model instances exceeding \texttt{MinScore} in the image should be found, \texttt{NumMatches} must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on \texttt{NumMatches}. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for \texttt{NumMatches} set to 1 might be different from the match with the highest score returned when setting \texttt{NumMatches} to 0 or \texttt{NumMatches} set to 0.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise \texttt{NumMatches}, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using \texttt{set_shape_model_clutter}, \texttt{NumMatches} also considers the second value passed in \texttt{MinScore}: If more than \texttt{NumMatches} instances with a score greater than the first entry of \texttt{MinScore} and a clutter value smaller than the second entry of \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances with respect to clutter are returned. Still, \texttt{MinScore} takes precedence over \texttt{NumMatches} and \texttt{NumMatches} must be set to 0 if all model instances fulfilling the conditions imposed by \texttt{MinScore} should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0.

If \texttt{NumMatches} contains one element, \texttt{find_scaled_shape_models} returns the best \texttt{NumMatches} instances of the model irrespective of the type of the model. If, for example, two models are passed in ModelIDs and \texttt{NumMatches} = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, \texttt{NumMatches} contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in \texttt{NumMatches}. If, for example, \texttt{NumMatches} = \{1, 1\} is selected, one instance of the first model and one instance of the second model is returned.

\textbf{MaxOverlap:} If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter \texttt{MaxOverlap} determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than \texttt{MaxOverlap} only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see \texttt{smallest_rectangle2}) of the found instances. If \texttt{MaxOverlap} = 0, the found instances may not overlap at all, while for \texttt{MaxOverlap} = 1 all instances are returned.

If a single value is passed in \texttt{MaxOverlap}, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in \texttt{MaxOverlap}, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

\textbf{SubPixel:} The parameter \texttt{SubPixel} determines whether the instances should be extracted with subpixel accuracy. If \texttt{SubPixel} is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with
create_scaled_shape_model. If SubPixel is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max_deformation' and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max_deformation' or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares_very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in ModelIDs exactly one value for the subpixel extraction must be passed in SubPixel. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in ModelIDs and for the first model the subpixel extraction is set to 'interpolation' and no object deformations are allowed and for the second model the subpixel extraction is set to 'least_squares' and a maximum object deformation of 3 pixels is allowed, then the tuple ['interpolation', 'least_squares', 'max_deformation 3'] must be passed in SubPixel. Alternatively, the equivalent tuple ['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3'] may be passed.

NumLevels: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_scaled_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_scaled_shape_model is used. In certain cases, the number of pyramid levels that was determined automatically with, for example, create_scaled_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_scaled_shape_models. This approach is often better regarding the speed and robustness of the matching.
The position, rotation, and scale of the found instances of the model are returned in Row, Column, Angle, and Scale. The coordinates Row and Column are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with \texttt{create_scaled_shape_model}. A different origin can be set with \texttt{set_shape_model_origin}.

Note that the coordinates Row and Column do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for search image.

Note also that for visualizing the model at the found position, also the procedure \texttt{dev_display_shape_matching_results} can be used.

Score: The score of each found instance is returned in Score. The score is a number between 0 and 1, which is
an approximate measure of how much of the model is visible in the image. If, for example, half of the model
is occluded, the score cannot exceed 0.5.
In case that the shape models have been extended by clutter parameters using
`set_shape_model_clutter`, following the above values `Score` also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, `Score = [0.9, 0.8, 0.2, 0.1]` is returned. Please note that all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Model:** The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to `|ModelIDs| − 1`. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`.

### Specifying a timeout

Using the operator `set_shape_model_param` you can specify a `'timeout'` for `find_scaled_shape_models`. If the shape models referenced by `ModelIDs` hold different values for `'timeout'`, `find_scaled_shape_models` uses the smallest one. If `find_scaled_shape_models` reaches this `'timeout'`, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling range specified by `ScaleMin` and `ScaleMax`, `find_scaled_shape_models` needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of `find_scaled_shape_models` exceeds the value of the specified `'timeout'` by this time.

### MinContrast with multiple models

Please note, that the different models that are given with the parameter `ModelIDs` should have been created with the same value of `MinContrast`. If they were created with different values for `MinContrast`, `find_scaled_shape_models` will use the smallest of these values.

### Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

### Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

---

**Parameters**

- **Image** (input_object) ...........................................(multichannel-)image(array)  \(\sim\) object : byte / uint2
  Input image in which the models should be found.
- **ModelIDs** (input_control) ........................................shape_model(array)  \(\sim\) handle
  Handle of the models.
- **AngleStart** (input_control) ...........................................angle.rad(array)  \(\sim\) real
  Smallest rotation of the models.
  Default value: -0.39
  Suggested values: AngleStart \(\in\) \([-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]\)
- **AngleExtent** (input_control) ............................................angle.rad(array)  \(\sim\) real
  Extent of the rotation angles.
  Default value: 0.78
  Suggested values: AngleExtent \(\in\) \([6.29, 3.14, 1.57, 0.79, 0.39, 0.0]\)
  Restriction: AngleExtent \(\geq\) 0
- **ScaleMin** (input_control) ..............................................number(array)  \(\sim\) real
  Minimum scale of the models.
  Default value: 0.9
  Suggested values: ScaleMin \(\in\) \([0.5, 0.6, 0.7, 0.8, 0.9, 1.0]\)
  Restriction: ScaleMin \(>\) 0
- **ScaleMax** (input_control) ..............................................number(array)  \(\sim\) real
  Maximum scale of the models.
  Default value: 1.1
  Suggested values: ScaleMax \(\in\) \([1.0, 1.1, 1.2, 1.3, 1.4, 1.5]\)
  Restriction: ScaleMax \(\geq\) ScaleMin
18.5. SHAPE-BASED

- **MinScore** (input_control) ................................................. real(-array) $\sim$ real
  Minimum score of the instances of the models to be found.
  Default value: 0.5
  Suggested values: MinScore $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: $0 \leq$ MinScore $\leq$ 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) ............................................. integer(-array) $\sim$ integer
  Number of instances of the models to be found (or 0 for all matches).
  Default value: 1
  Suggested values: NumMatches $\in$ {0, 1, 2, 3, 4, 5, 10, 20}

- **MaxOverlap** (input_control) ............................................. real(-array) $\sim$ real
  Maximum overlap of the instances of the models to be found.
  Default value: 0.5
  Suggested values: MaxOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: $0 \leq$ MaxOverlap $\leq$ 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **SubPixel** (input_control) .................................................. string(-array) $\sim$ string
  Subpixel accuracy if not equal to 'none'.
  Default value: 'least_squares'
  Suggested values: SubPixel $\in$ {'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}

- **NumLevels** (input_control) .............................................. integer(-array) $\sim$ integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if $|\text{NumLevels}| = 2$).
  Default value: 0
  List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **Greediness** (input_control) ............................................. real(-array) $\sim$ real
  "Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: Greediness $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Typical range of values: $0 \leq$ Greediness $\leq$ 1
  Minimum increment: 0.01
  Recommended increment: 0.05

- **Row** (output_control) ..................................................... point.y-array $\sim$ real
  Row coordinate of the found instances of the models.

- **Column** (output_control) ................................................. point.x-array $\sim$ real
  Column coordinate of the found instances of the models.

- **Angle** (output_control) ................................................... angle.rad-array $\sim$ real
  Rotation angle of the found instances of the models.

- **Scale** (output_control) ................................................... number-array $\sim$ real
  Scale of the found instances of the models.

- **Score** (output_control) ................................................... real-array $\sim$ real
  Score of the found instances of the models.

- **Model** (output_control) .................................................. integer-array $\sim$ integer
  Index of the found instances of the models.

---

**Example**

```
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_scaled_shape_model (ImageReduced1,'auto', -0.39, 0.79, 'auto', 0.9, 1.1, 'auto', 'auto', 'use_polarity', 'auto', 'auto', ModelID1)
```
create_scaled_shape_model (ImageReduced2, 'auto', -0.39, 0.79, 'auto', 0.9, 1.1, 'auto', 'auto', 'use_polarity', 'auto', 'auto', 'use_polarity', 'auto', ModelID2)

ModelIDs:=[ModelID1, ModelID2]

find_scaled_shape_models (Image, ModelIDs, -0.39, 0.78, 0.9, 1.1, 0.5, 1, 0.5, 'least_squares', 0, 0.9, Row, Column, Angle, Scale, Score, Model)

* Display results

dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, Scale, 1, Model)

Result

If the parameter values are correct, the operator find_scaled_shape_models returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Possible Predecessors

add_channels, create_scaled_shape_model, read_shape_model, set_shape_model_origin, set_shape_model_clutter

Possible Successors

clear_shape_model

Alternatives

Module

Matching

find_shape_model ( Image : : ModelID, AngleStart, AngleExtent, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, Score )

Find the best matches of a shape model in an image.

The operator find_shape_model finds the best NumMatches instances of the shape model ModelID in the input image Image. The model must have been created previously by calling create_shape_model or read_shape_model.

The position and rotation of the found instances of the model is returned in Row, Column, and Angle. Additionally, the score of each found instance is returned in Score.

Input parameters in detail

The image and its domain: The domain of the image Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with create_shape_model. A different origin set with set_shape_model_origin is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than
SHAPE-BASED

MinScore (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with \texttt{set_system(’border_shape_models’,’true’)} for all models or with \texttt{set_shape_model_param(ModelID, ’border_shape_models’,’true’)} for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than $\text{MinScore}$. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., \texttt{dilation_circle}.

\textbf{AngleStart} and \textbf{AngleExtent}: The parameters \texttt{AngleStart} and \texttt{AngleExtent} determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with \texttt{create_shape_model}. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. \texttt{AngleStart} and \texttt{AngleExtent} are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

\textbf{MinScore}: The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger \texttt{MinScore} is chosen, the faster the search is. If the model can be expected never to be occluded in the images, \texttt{MinScore} may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below \texttt{MinScore} are found.

In case that the shape model has been extended by clutter parameters with \texttt{set_shape_model_clutter} and thus ‘\texttt{use_clutter}’ is enabled, \texttt{MinScore} expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0. Changing this second value does not influence the runtime.

\textbf{NumMatches}: The maximum number of instances to be found can be determined with \texttt{NumMatches}. If more than \texttt{NumMatches} instances with a score greater than \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances are returned. If fewer than \texttt{NumMatches} are found, only that number is returned, i.e., the parameter \texttt{MinScore} takes precedence over \texttt{NumMatches}. If all model instances exceeding \texttt{MinScore} in the image should be found, \texttt{NumMatches} must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on \texttt{NumMatches}. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for \texttt{NumMatches} set to 1 might be different from the match with the highest score returned when setting \texttt{NumMatches} to 0 or $>1$. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise \texttt{NumMatches}, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using \texttt{set_shape_model_clutter}, \texttt{NumMatches} also considers the second value passed in \texttt{MinScore}. Matched instances will be in this case instances with a score greater than the first entry of \texttt{MinScore} and a clutter value smaller than its second entry. If the number of matched instances in the image is larger than \texttt{NumMatches}, the best \texttt{NumMatches} instances with respect to clutter values are returned. Still, \texttt{MinScore} takes precedence over \texttt{NumMatches} and \texttt{NumMatches} must be set to 0 if all model instances fulfilling the conditions imposed by \texttt{MinScore} should be returned. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0.

\textbf{MaxOverlap}: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter \texttt{MaxOverlap} determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than \texttt{MaxOverlap} only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see \texttt{smallest_rectangle2}) of the found instances. If \texttt{MaxOverlap} = 0, the found instances may not overlap at all, while for \texttt{MaxOverlap} = 1 all instances are returned.
SubPixel: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with create_shape_model. If SubPixel is set to 'interpolation' (or 'true') the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max_deformation' and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max_deformation' or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares_very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

NumLevels: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_shape_model is used. In certain cases, the number of pyramid levels that was determined automatically with, for example, create_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_shape_model. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least 'least_squares'. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection.
of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ’increased tolerance mode’, the lowest pyramid level must be specified negatively in \texttt{NumLevels}. If, e.g., \texttt{NumLevels} is set to \([4, -2]\), the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

\textbf{Greediness:} The parameter \texttt{Greediness} determines how “greedily” the search should be carried out. If \texttt{Greediness} = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If \texttt{Greediness} = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For \texttt{Greediness} = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for \texttt{Greediness} = 0.9.

\textbf{Output parameters in detail}

\textbf{Row, Column and Angle:} The position and rotation of the found instances of the model is returned in \texttt{Row}, \texttt{Column}, and \texttt{Angle}. The coordinates \texttt{Row} and \texttt{Column} are related to the position of the origin of the shape model in the search image. However, \texttt{Row} and \texttt{Column} do not exactly correspond to this position. Instead, \texttt{find_shape_model} returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see \texttt{affine_trans_pixel}). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with \texttt{create_aniso_shape_model}. A different origin can be set with \texttt{set_shape_model_origin}.

\textbf{Score:} The score of each found instance is returned in \texttt{Score}. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using \texttt{set_shape_model_clutter}, following the above values \texttt{Score} also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, \texttt{Score} = \([0.9, 0.8, 0.2, 0.1]\) is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

\textbf{Specifying a timeout}

Using the operator \texttt{set_shape_model_param} you can specify a ’timeout’ for \texttt{find_shape_model}. If \texttt{find_shape_model} reaches this ’timeout’, it terminates without results and returns the error code 9400 (\texttt{H_ERR_TIMEOUT}).

\textbf{Visualization of the results}

To display the results found by shape-based matching, we highly recommend the usage of the procedure \texttt{dev_display_shape_matching_results}.

\textbf{Further Information}

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter \textit{Transformations / 2D Transformations}. 
Parameters

▶ **Image** (input_object) .................................(multichannel-)image ˜ object : byte / uint2
   Input image in which the model should be found.

▶ **ModelID** (input_control) ............................ shape_model ˜ handle
   Handle of the model.

▶ **AngleStart** (input_control) .............................. angle.rad ˜ real
   Smallest rotation of the model.
   Default value: -0.39
   Suggested values: AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]

▶ **AngleExtent** (input_control) ............................. angle.rad
   Extent of the rotation angles.
   Default value: 0.79
   Suggested values: AngleExtent ∈ [6.29, 3.14, 1.57, 0.79, 0.39, 0.0]
   Restriction: AngleExtent ≥ 0

▶ **MinScore** (input_control) ................................. real(-array) ˜ real
   Minimum score of the instances of the model to be found.
   Default value: 0.5
   Suggested values: MinScore ∈ [0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
   Typical range of values: 0 ≤ MinScore ≤ 1
   Minimum increment: 0.01
   Recommended increment: 0.05

▶ **NumMatches** (input_control) .............................. integer
   Number of instances of the model to be found (or 0 for all matches).
   Default value: 1
   Suggested values: NumMatches ∈ {0, 1, 2, 3, 4, 5, 10, 20}

▶ **MaxOverlap** (input_control) ............................. real
   Maximum overlap of the instances of the model to be found.
   Default value: 0.5
   Suggested values: MaxOverlap ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
   Typical range of values: 0 ≤ MaxOverlap ≤ 1
   Minimum increment: 0.01
   Recommended increment: 0.05

▶ **SubPixel** (input_control) ................................. string(-array) ˜ string
   Subpixel accuracy if not equal to 'none'.
   Default value: 'least_squares'
   Suggested values: SubPixel ∈ {'none', 'interpolation', 'least_squares', 'least_squares_high',
   'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3',
   'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}

▶ **NumLevels** (input_control) .............................. integer(-array) ˜ integer
   Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
   Default value: 0
   List of values: NumLevels ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

▶ **Greediness** (input_control) .............................. real
   “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
   Default value: 0.9
   Suggested values: Greediness ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
   Typical range of values: 0 ≤ Greediness ≤ 1
   Minimum increment: 0.01
   Recommended increment: 0.05

▶ **Row** (output_control) ................................. point.y-array ˜ real
   Row coordinate of the found instances of the model.

▶ **Column** (output_control) ............................... point.x-array ˜ real
   Column coordinate of the found instances of the model.

▶ **Angle** (output_control) ................................. angle.rad-array ˜ real
   Rotation angle of the found instances of the model.

▶ **Score** (output_control) ................................. real-array ˜ real
   Score of the found instances of the model.
create_shape_model (ImageReduced, 0, rad(-45), rad(180), 0, \n'none', 'use_polarity', 30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_shape_model (SearchImage, ModelID, rad(-45), rad(180), \n0.5, 1, 0.5, 'interpolation', \n0, 0, Row, Column, Angle, Score)

* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2DObject)
* Display results
dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \n1, 1, 0)

Result
If the parameter values are correct, the operator find_shape_model returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Possible Predecessors
create_shape_model, read_shape_model, set_shape_model_origin, set_shape_model_clutter

Possible Successors
clear_shape_model

Module

find_shape_models ( Image : ModelIDs, AngleStart, AngleExtent, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, Score, Model )

Find the best matches of multiple shape models.
The operator find_shape_models finds the best NumMatches instances of the shape models that are passed in the tuple ModelIDs in the input image Image. The models must have been created previously by calling create_shape_model or read_shape_model. In contrast to find_shape_model, multiple models can be searched in the same image in one call.
The position and rotation of the found instances of the model is returned in Row, Column, and Angle. The score of each found instance is returned in Score. The type of the found instances of the models is returned in Model.
For details see respective sections below.

Characteristics of the parameter semantics
Compared to find_shape_model, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain
same number of elements as ModelIDs, in which case each parameter element refers to the corresponding element in ModelIDs. (NumLevels may also contain either two or twice the number of elements as ModelIDs.) More details can be found below in the sections containing information for the respective parameters. Note that a call to find_shape_models with multiple values for ModelIDs, NumMatches and MaxOverlap has the same effect as multiple independent calls to find_shape_model with the respective parameters. However, a single call to find_shape_models is considerably more efficient.

Input parameters in detail

The image and its domain: The domain of the Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with create_shape_model. A different origin set with set_shape_model_origin is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with set_system('border_shape_models','true') for all models or with set_shape_model_param(ModelID, 'border_shape_models','true') for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than MinScore. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., dilation_circle.

As usual, the domain of the input Image is used to restrict the search space for the reference point of the models ModelIDs. Consistent with the above semantics, the input Image can therefore contain a single image object or an image object tuple containing multiple image objects. If Image contains a single image object, its domain is used as the region of interest for all models in ModelIDs. If Image contains multiple image objects, each domain is used as the region of interest for the corresponding model in ModelIDs. In this case, the images have to be identical except for their domains, i.e., Image cannot be constructed in an arbitrary manner using concat_obj, but must be created from the same image using add_channels or equivalent calls. If this is not the case, an error message is returned.

AngleStart and AngleExtent: The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with create_shape_model. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. AngleStart and AngleExtent are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

If a single value is passed in MinScore, this value is applied to found instances of all models. If, on the other hand, MinScore contains multiple values, the values are applied separately for the respective model. In case that the shape models have been extended by clutter parameters with set_shape_model_clutter and thus 'use_clutter’ is enabled, MinScore expects for each minimum score an additional value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for 'use_clutter’.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, MinScore must contain twice the number of elements as ModelIDs. In this case, the minimum score and the maximum clutter must be specified interleaved in MinScore. If,
The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter value smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

If `NumMatches` contains one element, `find_shape_models` returns the best `NumMatches` instances of the model irrespective of the type of the model. If, for example, two models are passed in `ModelIDs` and `NumMatches` = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, `NumMatches` contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in `NumMatches`. If, for example, `NumMatches` = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.

If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to `none` (or `false` for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with `create_shape_model`. If `SubPixel` is set to `interpolation` (or `true`) the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to `interpolation`, this mode requires additional computation time. The different modes for least-squares adjustment (`least_squares`, `least_squares_high`, and `least_squares_very_high`) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to `interpolation`. If least-squares adjustment is desired, `least_squares` should be chosen because this results in the best trade-off between runtime and accuracy.
Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value ‘max_deformation’ followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value ‘max_deformation 2’ must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value ‘max_deformation 0’ corresponds to a search without allowing deformations, i.e., the behavior is the same as if no ‘max_deformation’ is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if ‘max_deformation’ and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either ‘max_deformation’ or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if ‘least_squares’, ‘least_squares_high’, or ‘least_squares_very_high’ (see above) is chosen for the subpixel extraction (in comparison to ‘none’ or ‘interpolation’). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in ModelIDs exactly one value for the subpixel extraction must be passed in SubPixel. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in ModelIDs and for the first model the subpixel extraction is set to ‘interpolation’ and no object deformations are allowed and for the second model the subpixel extraction is set to ‘least_squares’ and a maximum object deformation of 3 pixels is allowed, then the tuple ['interpolation', 'least_squares', 'max_deformation 3'] must be passed in SubPixel. Alternatively, the equivalent tuple ['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3'] may be passed.

**NumLevels:** The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_shape_models. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least ‘least_squares’. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, NumLevels must contain twice the
number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model. `NumLevels = [5, 2, 4, 1]` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[-5, 2, 4, -1]`, the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to `-1`. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

**Greediness:** The parameter `Greediness` determines how “greedily” the search should be carried out. If `Greediness = 0`, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness = 1`, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness = 1`, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness = 0.9`.

**Output parameters in detail**

**Row, Column and Angle:** The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The coordinates `Row` and `Column` are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`. A different origin can be set with `set_shape_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_shape_model` shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure `dev_display_shape_matching_results` can be used.

**Score:** The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, `Score = [0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Model:** The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to `|ModelIDs| - 1`. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`. 
Specifying a timeout

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_shape_models`. If the shape models referenced by ModelIDs hold different values for 'timeout', `find_shape_models` uses the smallest one. If `find_shape_models` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

MinContrast with multiple models

Please note, that the different models that are given with the parameter ModelIDs should have been created with the same value of MinContrast. If they were created with different values for MinContrast, `find_shape_models` will use the smallest of these values.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

---

**Parameters**

- `Image` (input_object) .................................(multichannel)-image(-array) \(\sim\) object : byte / uint2
  Input image in which the models should be found.

- `ModelIDs` (input_control) ................................. shape_model(-array) \(\sim\) handle
  Handle of the models.

- `AngleStart` (input_control) ................................. angle.rad(-array) \(\sim\) real
  Smallest rotation of the models.
  
  - Default value: -0.39
  - Suggested values: \(\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)

- `AngleExtent` (input_control) ................................. angle.rad(-array) \(\sim\) real
  Extent of the rotation angles.
  
  - Default value: 0.79
  - Suggested values: \(\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)
  - Restriction: \(\text{AngleExtent} \geq 0\)

- `MinScore` (input_control) ................................. real(-array) \(\sim\) real
  Minimum score of the instances of the models to be found.
  
  - Default value: 0.5
  - Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  - Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
  - Minimum increment: 0.01
  - Recommended increment: 0.05

- `NumMatches` (input_control) ................................. integer(-array) \(\sim\) integer
  Number of instances of the models to be found (or 0 for all matches).
  
  - Default value: 1
  - Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)

- `MaxOverlap` (input_control) ................................. real(-array) \(\sim\) real
  Maximum overlap of the instances of the models to be found.
  
  - Default value: 0.5
  - Suggested values: \(\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  - Typical range of values: \(0 \leq \text{MaxOverlap} \leq 1\)
  - Minimum increment: 0.01
  - Recommended increment: 0.05

- `SubPixel` (input_control) ................................. string(-array) \(\sim\) string
  Subpixel accuracy if not equal to 'none'.
  
  - Default value: 'least_squares'
  - Suggested values: \(\text{SubPixel} \in \{'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'\}\)
18.5. SHAPE-BASED

- **NumLevels** (input_control) ................................................ integer(-array) $\leadsto$ integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if $|\text{NumLevels}| = 2$).
  Default value: 0
  List of values: $\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- **Greediness** (input_control) .................................................. real(-array) $\leadsto$ real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: $\text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Typical range of values: $0 \leq \text{Greediness} \leq 1$
  Minimum increment: 0.01
  Recommended increment: 0.05

- **Row** (output_control) ......................................................... point.y-array $\leadsto$ real
  Row coordinate of the found instances of the models.

- **Column** (output_control) .................................................... point.x-array $\leadsto$ real
  Column coordinate of the found instances of the models.

- **Angle** (output_control) ..................................................... angle.rad-array $\leadsto$ real
  Rotation angle of the found instances of the models.

- **Score** (output_control) .................................................... real-array $\leadsto$ real
  Score of the found instances of the models.

- **Model** (output_control) .................................................... integer-array $\leadsto$ integer
  Index of the found instances of the models.

--- Example ---

```halcon
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_shape_model (ImageReduced1, 0, rad(-45), rad(180), 0, 'none', 'use_polarity', 30, 10, ModelID1)
create_shape_model (ImageReduced2, 0, rad(-45), rad(180), 0, 'none', 'use_polarity', 30, 10, ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_shape_models (Image, ModelIDs, rad(-45), rad(90), 0.7, [1,1], 0.5, 'least_squares', 0, 1, Row, Column, Angle, Score, Model)
* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, 1, 1, Model)
```

--- Result ---

If the parameter values are correct, the operator `find_shape_models` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result',<Result>). If necessary, an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

HALCON 20.05.0.0
get_shape_model_clutter (: ClutterRegion : ModelID, GenParamName : GenParamValue, HomMat2D, ClutterContrast )

Get the clutter parameters of a shape model.

The operator get_shape_model_clutter can be used to inspect clutter parameters of the shape model ModelID, which have been set previously using set_shape_model_clutter. Also, the value of 'use_clutter', which can be set using set_shape_model_param, can be queried by setting GenParamName to 'use_clutter'. For a description of the parameters, please see set_shape_model_clutter and set_shape_model_param.

Parameters

▷ ClutterRegion (output_object) ... Region where no clutter should occur.
▷ ModelID (input_control) ... Handle of the model.
▷ GenParamName (input_control) ... Parameter names.
  Default value: 'use_clutter'
  List of values: GenParamName ∈ {'use_clutter', 'clutter_border_mode'}
▷ GenParamValue (output_control) ... Parameter values.
▷ HomMat2D (output_control) ... Transformation matrix.
▷ ClutterContrast (output_control) ... Minimum contrast of clutter in the search images.

Result

If the parameters are valid, the operator get_shape_model_clutter returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching
**get_shape_model_contours** ( : ModelContours : ModelID, Level : )

Return the contour representation of a shape model.

The operator `get_shape_model_contours` returns a representation of the shape model `ModelID` as XLD contours in `ModelContours`. The parameter `Level` determines for which pyramid level of the model the contour representation should be returned. The contours can be used, for example, to visualize the found instances of the model in an image. It should be noted that the position of `ModelContours` is normalized such that the reference point of the model (see `set_shape_model_origin`) lies at the pixel position $(0,0)$. Hence, the contours simply need to be translated to the found position in the image (and possibly rotated and scaled around this point).

**Parameters**

- **ModelContours** (output_object) : xld_cont-array ~ object
  Contour representation of the shape model.
- **ModelID** (input_control) : shape_model ~ handle
  Handle of the model.
- **Level** (input_control) : integer ~ integer
  Pyramid level for which the contour representation should be returned.
  Default value: 1
  Suggested values: Level ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
  Restriction: Level >= 1

**Result**

If the handle of the model is valid, the operator `get_shape_model_contours` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**See also**

`find_shape_model, find_scaled_shape_model, find_aniso_shape_model, find_shape_models, find_scaled_shape_models, find_aniso_shape_models`

**Module**

Matching

**get_shape_model_origin** ( : : ModelID : Row, Column )

Return the origin (reference point) of a shape model.

The operator `get_shape_model_origin` returns the origin (reference point) of the shape model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. Hence, an origin of $(0,0)$ means that the center of gravity of the domain of the model image is used as the origin. An origin of $(-20,-40)$ means that the origin lies to the upper left of the center of gravity.

**Parameters**

- **ModelID** (input_control) : shape_model ~ handle
  Handle of the model.
- **Row** (output_control) : point.y ~ real
  Row coordinate of the origin of the shape model.
**get_shape_model_params** (ModelID : NumLevels, AngleStart, AngleExtent, AngleStep, ScaleMin, ScaleMax, ScaleStep, Metric, MinContrast)

*Return the parameters of a shape model.*

The operator get_shape_model_params returns the parameters of the shape model ModelID that were used to create it using create_shape_model, create_scaled_shape_model, or create_aniso_shape_model. In particular, this output can be used to check the parameters NumLevels, AngleStep, ScaleStep, and MinContrast if they were determined automatically during the model creation with create_shape_model, create_scaled_shape_model, or create_aniso_shape_model.

If the shape model was created using create_shape_model or create_scaled_shape_model a single value is returned in ScaleMin, ScaleMax, and ScaleStep. This parameters corresponds to the isotropic scaling parameters of the shape model. If the shape model was created using create_aniso_shape_model two values each are returned in the above three parameters. Here, the first value of the respective parameter refers to the scaling in the row direction, while the second value refers to the scaling in the column direction.

Note that the parameters Optimization and Contrast that also can be determined automatically during the model creation cannot be queried by using get_shape_model_params. If their value is of interest determine_shape_model_params should be used instead.

**Parameters**

- **ModelID** (input_control) Handle of the model.
- **NumLevels** (output_control) Number of pyramid levels.
- **AngleStart** (output_control) Smallest rotation of the pattern.
- **AngleExtent** (output_control) Extent of the rotation angles.
- **AngleStep** (output_control) Step length of the angles (resolution).
  
  **Assertion:** AngleExtent >= 0
  
  **Assertion:** AngleStep >= 0 & & AngleStep <= pi / 16

**Result**

If the handle of the model is valid, the operator get_shape_model_origin returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

\begin{verbatim}
inspect\_shape\_model \(\sim\) ( Image : ModelImages, 
ModelRegions : NumLevels, Contrast : )
\end{verbatim}

Create the representation of a shape model.

\texttt{inspect\_shape\_model} creates a representation of a shape model. The operator is particularly useful in order
to determine the parameters \texttt{NumLevels} and \texttt{Contrast}, which are used in \texttt{create\_shape\_model,}
\texttt{create\_scaled\_shape\_model, or create\_aniso\_shape\_model,} quickly and conveniently. The
terresentation of the model is created on multiple image pyramid levels, where the number of levels is
determined by \texttt{NumLevels}. In contrast to \texttt{create\_shape\_model, create\_scaled\_shape\_model,}
and \texttt{create\_aniso\_shape\_model,} the model is only created for the rotation and scale of the
object in the input image, i.e., 0\(^\circ\) and 1. As output, \texttt{inspect\_shape\_model} creates an image object
\texttt{ModelImages} containing the images of the individual levels of the image pyramid as well as a region in
\texttt{ModelRegions} for each pyramid level that represents the model at the respective pyramid level.
The individual objects can be accessed with \texttt{select\_obj}. If the input image \texttt{Image} has one channel
the representation of the model is created with the method that is used in \texttt{create\_shape\_model,}
\texttt{create\_scaled\_shape\_model, or create\_aniso\_shape\_model,} for the metrics \texttt{'use\_polarity',}
\texttt{'ignore\_global\_polarity', and 'ignore\_local\_polarity'}. If the input image has more than one channel the representation
is created with the method that is used for the metric \texttt{'ignore\_color\_polarity'}. As described for
\texttt{create\_shape\_model, create\_scaled\_shape\_model, and create\_aniso\_shape\_model,} the
number of pyramid levels should be chosen as large as possible, while taking into account that the model must
be recognizable on the highest pyramid level and must have enough model points. The parameter \texttt{Contrast}
should be chosen such that only the significant features of the template object are used for the model. \texttt{Contrast}
can also contain a tuple with two values. In this case, the model is segmented using a method similar to the
hysteresis threshold method used in edges_image. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see hysteresis_threshold. Optionally, Contrast can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in Contrast. In this case, the first two values can simply be set to identical values. In its typical use, inspect_shape_model is called interactively multiple times with different parameters for NumLevels and Contrast, until a satisfactory model is obtained. After this, create_shape_model, create_scaled_shape_model, or create_aniso_shape_model are called with the parameters thus obtained.

---

### Parameters

- **Image** (input_object) (multichannel-)image ∼ object : byte / uint2
  Input image.
- **ModelImages** (output_object) (multichannel-)image-array ∼ object : byte / uint2
  Image pyramid of the input image
- **ModelRegions** (output_object) region-array ∼ object
  Model region pyramid
- **NumLevels** (input_control) integer
  Number of pyramid levels.
  Default value: 4
  List of values: NumLevels ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- **Contrast** (input_control) number(-array) ∼ integer
  Threshold or hysteresis thresholds for the contrast of the object in the image and optionally minimum size of the object parts.
  Default value: 30
  Suggested values: Contrast ∈ {10, 20, 30, 40, 60, 80, 100, 120, 140, 160}

---

### Result

If the parameters are valid, the operator inspect_shape_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**read_shape_model** ( : : FileName : : ModelID )

Read a shape model from a file.

The operator read_shape_model reads a shape model, which has been written with write_shape_model, from the file FileName. The default HALCON file extension for the shape model is 'shm'.

---

Parameters

File Name (input_control) .......................... filename.read  \rightarrow string
   File name.
File extension: .shm
Model ID (output_control) .......................... shape_model  \rightarrow handle
   Handle of the model.

Result

If the file name is valid, the operator read_shape_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

**serialize_shape_model** ( : : ModelID : SerializedItemHandle )

Serialize a shape model.

serialize_shape_model serializes the data of a shape model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_shape_model is converted to a serialized item. The shape model is defined by the handle ModelID. The serialized shape model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_shape_model.

Parameters

ModelID (input_control) .......................... shape_model  \rightarrow handle
   Handle of the model.
SerializedItemHandle (output_control) .......................... serialized_item  \rightarrow handle
   Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_shape_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

Matching

set_shape_model_clutter( ClutterRegion : : ModelID, HomMat2D,
                        ClutterContrast, GenParamName, GenParamValue : )

Set the clutter parameters of a shape model.

set_shape_model_clutter sets the clutter parameters of the shape model ModelID. In particular, a region is defined relative to the model contours, in which no (or too faint) clutter edges should occur in the search image. This is helpful, e.g., if it is a special characteristic of the model that, in specific parts near to the model, structures are missing.

For example, within the HDevelop example program find_shape_model_clutter.hdev, the model corresponds to a ball in a ball grid array (BGA). As the ball grid array represents a repeating pattern, many matches are returned when matching is applied without considering the neighborhood of the model. By defining a clutter region, the search can be restricted to specific instances of the model.

(1) Image of ball grid array, (2) shape model of a single ball of the array (orange), (3) matching result without using clutter parameters (green), (4) defining the clutter region (yellow) relative to the model (orange), (5) matching result using clutter parameters (green).

For matches found in a search image, edges within the clutter region increase the resulting clutter values. These are returned by find_shape_model, find_scaled_shape_model, find_aniso_shape_model, find_shape_models, find_scaled_shape_models, and find_aniso_shape_models in the parameter Score, following the common values measuring how much of the model is visible in the image. Note that the input parameter MinScore of those operators additionally expects information specifying the maximum clutter value up to which matches should be returned. For more information regarding the setting of MinScore, please refer to the respective operator reference.

To define the clutter region relative to the model contours, you need the region ClutterRegion and the transformation matrix HomMat2D that maps the model contours to the respective position where the object appears in an image. Typically, you obtain them by searching for a model instance in an image, e.g., with the operator find_shape_model. Then, the transformation matrix can be determined with the procedure get_hom_mat2d_from_matching_result using the respective output parameters of the search. The region ClutterRegion is specified within the same image. Note that ClutterRegion should contain the regions around the superfluous edges that are typical for all expected manifestations of the matches. We recommend that the clutter region is chosen larger than necessary when large scale ranges are searched. Furthermore, choosing the clutter region not too near to the expected model contours can increase the robustness.

The parameter ClutterContrast determines the contrast the edges in the clutter region must have in order to be counted as clutter. In many applications, the parameter Contrast, which has been used to create the shape
model, is also a reasonable choice for ClutterContrast. ClutterContrast may not be smaller than the parameter MinContrast of the shape model, otherwise an error is raised at runtime. The polarity of the found clutter edges is ignored, i.e., bright objects on a dark background will yield the same clutter value as dark objects on a bright background, independent of the parameter Metric of the shape model. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

With GenParamName set to 'clutter_border_mode', the behavior of the clutter value can be influenced in cases where the clutter region of a found match is not entirely contained in the image domain. The corresponding values for 'clutter_border_mode' (GenParamValue) can be 'clutter_border_average' or 'clutter_border_empty'.

- 'clutter_border_average':
  When GenParamValue is set to 'clutter_border_average' (default), the hidden part of the clutter region is assumed to be filled on average as is its visible part. If the clutter region is not visible at all, the clutter value of the found match is set to 0.0.

- 'clutter_border_empty':
  When GenParamValue is set to 'clutter_border_empty', the clutter region is assumed to be empty where it is not visible.

Note that GenParamValue set to 'clutter_border_average' results in higher clutter values.

The use of clutter parameters can be disabled and enabled by calling set_shape_model_param. For newly created shape models, the use of clutter parameters is disabled. After calling set_shape_model_clutter, the use of clutter parameters is enabled. Depending on the activation status for the use of clutter parameters, the find operators, e.g., find_shape_model, expect a different number of entries in the input parameter MinScore. The set clutter parameters and the value of 'use_clutter' can be queried using the operator get_shape_model_clutter.

---

### Parameters

- **ClutterRegion** (input_object) region ↦ object Region where no clutter should occur.
- **ModelID** (input_control) shape_model ↦ handle Handle of the model.
- **HomMat2D** (input_control) hom_mat2d ↦ real Transformation matrix.
- **ClutterContrast** (input_control) number ↦ integer Minimum contrast of clutter in the search images. Default value: 128
- **GenParamName** (input_control) attribute.name(-array) ↦ string Parameter names. List of values: GenParamName ∈ {'clutter_border_mode'}
- **GenParamValue** (input_control) attribute.value(-array) ↦ real / integer / string Parameter values. List of values: GenParamValue ∈ {'clutter_border_empty', 'clutter_border_average'}

Module

set_shape_model_metric ( Image : : ModelID, HomMat2D, Metric : )

Set the metric of a shape model that was created from XLD contours.
set_shape_model_metric changes the value of the parameter Metric that was selected during the creation of the shape model ModelID from XLD contours. For this, the polarity of the model edges is determined based on the image Image. The transformation that maps the model edges to the image position where the respective object appears is given in HomMat2D.

The parameter Metric determines the conditions under which the model is recognized later in the search image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for
example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If \( \text{Metric} = \text{'ignore\_global\_polarity'} \), the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of \text{find\_shape\_model} will increase slightly in this case.

It must be ensured that the object edges in the \text{Image} have the same (or inverse) polarity as the object edges in the image in which the object must be searched later. Especially, the object must not be occluded in the \text{Image} and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model edges will not represent the polarity of the object edges during the search. Note that only the polarity of the edges is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multichannel image is passed in \text{Image}, only the first channel will be used (and no error message will be returned).

The transformation defined by the matrix \text{HomMat2D} maps the model contours to the respective position where the object appears in the \text{Image}. It can be obtained by finding the object in the \text{Image}, e.g., with the operator \text{find\_shape\_model} and determining the respective transformation matrix with the procedure \text{get\_hom\_mat2d\_from\_matching\_result}. The operator \text{set\_shape\_model\_metric} ignores an origin that was set by \text{set\_shape\_model\_origin} and always assumes (0,0) as the origin. Hence, when finding the object in the \text{Image}, all other operators must have the origin at the point (0,0). Therefore, \text{set\_shape\_model\_origin} must be called with (0,0) as the origin.

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the shape model must be created from the XLD contours by setting the parameter \text{Metric} to \text{'ignore\_local\_polarity'}. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter \text{Metric} can be changed, e.g., to \text{'use\_polarity'}. This leads to a faster and more robust recognition in the following images.

---

**Attention**

\text{set\_shape\_model\_metric} can only be used with shape models that were created from XLD contours.

---

**Parameters**

- \text{Image} (input_object) \text{--- singlechannelimage} \text{\sim object : byte / uint2}

  Input image used for the determination of the polarity.

- \text{ModelID} (input_control) \text{--- shape\_model \sim handle}

  Handle of the model.

- \text{HomMat2D} (input_control) \text{--- hom\_mat2d \sim real}

  Transformation matrix.

- \text{Metric} (input_control) \text{--- string}

  Match metric.

  Default value: \text{'use\_polarity'}

  List of values: \text{Metric} \text{\in} \{ \text{'use\_polarity'}, \text{'ignore\_local\_polarity'} \}

---

**Example**

```plaintext
* Read the contours from file
read_contour_xld_dxf (Contours, 'metal-part-01', [], [], DxfStatus)
*
* Scale the contours such that they correspond to the image
hom_mat2d_identity (HomMat2DIdentity)
hom_mat2d_scale (HomMat2DIdentity, 3.35, 3.35, 0, 0, HomMat2DScale)
affine_trans_contour_xld (Contours, ContoursAffineTrans, HomMat2DScale)
*
* Create the shape model with \text{Metric='ignore\_local\_polarity'}
create_shape_model_xld (ContoursAffineTrans, 'auto', rad(0), rad(360), \n    'auto', 'auto', 'ignore\_local\_polarity', 5, ModelID)
*
* Get an image of the object and try to find the object in this image
read_image (Image, 'metal-parts/metal-parts-01')
find_shape_model (Image, ModelID, rad(0), rad(360), 0.5, 1, 0.5, \n```
'least_squares', 0, 0.9, Row, Column, Angle, Score)

* Visualize the match
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2D)
get_shape_model_contours (ModelContours, ModelID, 1)
affine_trans_contour_xld (ModelContours, ModelContoursAffineTrans, HomMat2D)

* Set the matching metric to 'use_polarity', based on the position
* of the found object
set_shape_model_metric (Image, ModelID, HomMat2D, 'use_polarity')

* Use the shape model to detect the object faster and more robust
read_image (Image, 'metal-parts/metal-parts-02')
find_shape_model (Image, ModelID, rad(0), rad(360), 0.5, 0, 0.5, \n'least_squares', 0, 0.9, Row, Column, Angle, Score)

* Visualize the matches
for Index := 0 to |Score|-1 by 1
   vector_angle_to_rigid (0, 0, 0, Row[Index], Column[Index], Angle[Index], \n   HomMat2D)
   affine_trans_contour_xld (ModelContours, ModelContoursAffineTrans, \n   HomMat2D)
endfor

--- Result ---
If the parameters are valid, the operator set_shape_model_metric returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

--- Possible Predecessors ---

create_aniso_shape_model_xld

--- Module ---

Matching

set_shape_model_origin ( : : ModelID, Row, Column : )

Set the origin (reference point) of a shape model.
The operator set_shape_model_origin sets the origin (reference point) of the shape model ModelID to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that
was used to create the shape model with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

---

**Parameters**

- **ModelID** (input_control) .................................................. handle
  Handle of the model.
- **Row** (input_control) ......................................................... point.y ↦ real
  Row coordinate of the origin of the shape model.
- **Column** (input_control) ...................................................... point.x ↦ real
  Column coordinate of the origin of the shape model.

---

**Result**

If the handle of the model is valid, the operator `set_shape_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Module**

**Matching**

---

```cpp
set_shape_model_param ( ModelID, GenParamName,
GenParamValue )
```

Set selected parameters of the shape model.

The operator `set_shape_model_param` sets the selected parameters `GenParamName` in the shape model `ModelID`. The following parameters can be modified:

- **'min_contrast'**

  Sets the minimum contrast of the object in the search images for the shape model `ModelID`. Thereby, the value of **'min_contrast'** that was originally set, e.g. with `create_shape_model`, is overwritten for the shape model `ModelID`. Note that if the shape model `ModelID` was read from file and if this file should be changed as well, the shape model `ModelID` must again be written to file after the execution of the operator `set_shape_model_param`.

- **'timeout'**

  Sets the maximum runtime of the operators used to find the shape model `ModelID` (e.g. `find_shape_model`). This is especially useful in cases where a maximum cycle time has to be ensured. The **'timeout'** must be given in

HALCON 20.05.0.0
milliseconds. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the ‘timer_mode’ set via set_system. Be aware that the runtime of the search increases by up to 10 percent with activated timeout. To disable the timeout you can either use a negative value or ‘false’.

‘border_shape_models’

This parameter determines whether the shape model ModelID to be found with, e.g., find_shape_model, may lie partially outside the image (i.e., whether they may cross the image border). The value of ‘border_shape_models’ can be ‘true’, ‘false’, or ‘system’. The value ‘system’ is the default behavior and uses the system-wide used value that was set by set_system for the parameter ‘border_shape_models’.

‘use_clutter’

Disables or enables the use of clutter parameters for the shape model ModelID, which have been set previously using set_shape_model_clutter. The value of ‘use_clutter’ can be ‘true’ or ‘false’. Note that the value of ‘use_clutter’ affects the expected number of entries in the input parameter MinScore of the find operators. Please refer to the documentation of the different find operators, e.g., find_shape_model.

For newly created shape models, the use of clutter parameters is disabled. After calling set_shape_model_clutter, the use of clutter parameters is enabled. Clutter parameters and the value of ‘use_clutter’ can be queried using get_shape_model_clutter.

---

**Parameters**

- **ModelID** (input_control)  
  Handle of the model.

- **GenParamName** (input_control)  
  Parameter names.  
  List of values: GenParamName ∈ {‘min_contrast’, ‘timeout’, ‘border_shape_models’, ‘use_clutter’}

- **GenParamValue** (input_control)  
  Parameter values.  
  List of values: GenParamValue ∈ {‘true’, ‘false’, ‘system’}

---

**Result**

If the parameters are valid, the operator set_shape_model_param returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**write_shape_model** ( : : ModelID, FileName : )

Write a shape model to a file.

The operator write_shape_model writes a shape model to the file FileName. The model can be read again with read_shape_model. The default HALCON file extension for the shape model is 'shm'.

Parameters

- **ModelID** (input_control) .................................................. shape_model ~ handle
  Handle of the model.
- **FileName** (input_control) .................................................. filename.write ~ string
  File name.
  **File extension**: .shm

Result

If the file name is valid (write permission), the operator write_shape_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Chapter 19

Matrix

19.1 Access

\texttt{get\_diagonal\_matrix} ( MatrixID, Diagonal : VectorID )

Get the diagonal elements of a matrix.

The operator \texttt{get\_diagonal\_matrix} generates a new matrix \texttt{Vector} and copies the diagonal elements of the \texttt{Matrix} to this new matrix. The \texttt{Matrix} is defined by the matrix handle \texttt{MatrixID}. The matrix \texttt{Vector} has one column and \( n \) rows, where \( n \) = number of diagonal elements. The operator returns the matrix handle \texttt{VectorID} of the matrix \texttt{Vector}. Access to the elements of the matrix is possible e.g. with the operator \texttt{get\_full\_matrix}.

If \texttt{Diagonal} = 0, the output of the \texttt{Vector} is the main diagonal of the \texttt{Matrix}.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix} \quad \text{Diagonal} = 0
\]

\[
\rightarrow \text{Vector} = \begin{bmatrix}
3.0 \\
7.0 \\
1.0
\end{bmatrix}
\]

If \texttt{Diagonal} is positive, the output \texttt{Vector} is the \texttt{Diagonal}-th super-diagonal of the \texttt{Matrix}.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix} \quad \text{Diagonal} = 2
\]

\[
\rightarrow \text{Vector} = \begin{bmatrix}
-2.0 \\
6.0
\end{bmatrix}
\]

If \texttt{Diagonal} is negative, the \texttt{Diagonal}-th sub-diagonal of the \texttt{Matrix} is copied.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix} \quad \text{Diagonal} = -1
\]

\[
\rightarrow \text{Vector} = \begin{bmatrix}
-5.0 \\
-4.0
\end{bmatrix}
\]
CHAPTER 19 MATRIX

Parameters

- **MatrixID** (input_control) .......................................................... matrix  \(\rightarrow\) handle
  Matrix handle of the input matrix.

- **Diagonal** (input_control) .......................................................... integer  \(\rightarrow\) integer
  Number of the desired diagonal.
  Default value: 0
  Suggested values: Diagonal \(\in\) \{-20, -10, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}

- **VectorID** (output_control) .......................................................... matrix  \(\rightarrow\) handle
  Matrix handle containing the diagonal elements.

Result

If the parameters are valid, the operator `get_diagonal_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### get_full_matrix ( : : MatrixID : Values )

Return all values of a matrix.

The operator `get_full_matrix` returns the values of all elements of the `Matrix` given by the matrix handle `MatrixID`. The output parameter `Values` is a tuple of floating point numbers and contains all values in a row-major order, i.e., line by line.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0 \\
\end{bmatrix} \rightarrow \quad \text{Values} = [3.0, 1.0, -2.0, -5.0, 7.0, 2.0, -9.0, -4.0, 1.0]
\]

Parameters

- **MatrixID** (input_control) .......................................................... matrix  \(\rightarrow\) handle
  Matrix handle of the input matrix.

- **Values** (output_control) .......................................................... real(-array)  \(\rightarrow\) real
  Values of the matrix elements.

Result

If the parameters are valid, the operator `get_full_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
19.1. ACCESS

- Processed without parallelization.

**get_sub_matrix** (: : MatrixID, Row, Column, RowsSub, ColumnsSub : MatrixSubID)

Get a sub-matrix of a matrix.

The operator `get_sub_matrix` generates a new matrix `MatrixSub` and copies to this matrix a part of the input `Matrix` defined by the matrix handle `Matrix`. The part of the `Matrix` is determined by the upper left corner `(Row, Column)` and the sub-matrix dimensions `(RowsSub, ColumnsSub)`. The operator returns the matrix handle `MatrixSubID` of the matrix `MatrixSub`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix}
\]

Row = 0  Column = 1  RowsSub = 3  ColumnsSub = 2

\[
\rightarrow MatrixSub = \begin{bmatrix}
1.0 & -2.0 \\
7.0 & 2.0 \\
-4.0 & 1.0
\end{bmatrix}
\]

Attention

The conditions 0 ≤ Row < size of Matrix in row direction, Row + RowsSub ≤ size of Matrix in the row direction, 0 ≤ Column < size of Matrix in the column direction, and Column + ColumnsSub ≤ size of matrix Matrix in the column direction must be satisfied.

Parameters

- **MatrixID** (input_control) ................................................................. matrix  \(\rightarrow\) handle
  Matrix handle of the input matrix.

- **Row** (input_control) ................................................................. integer  \(\rightarrow\) integer
  Upper row position of the sub-matrix in the input matrix.
  **Default value:** 0
  **Suggested values:** Row ∈ \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** Row ≥ 0

- **Column** (input_control) ................................................................. integer  \(\rightarrow\) integer
  Left column position of the sub-matrix in the input matrix.
  **Default value:** 0
  **Suggested values:** Column ∈ \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** Column ≥ 0

- **RowsSub** (input_control) ................................................................. integer  \(\rightarrow\) integer
  Number of rows of the sub-matrix.
  **Default value:** 1
  **Suggested values:** RowsSub ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** RowsSub ≥ 1
Chapter 19: Matrix

- **ColumnsSub** (input_control) .......................................................... integer \(\mapsto\) integer
  Number of columns of the sub-matrix.
  **Default value:** 1
  **Suggested values:** ColumnsSub \(\in\) \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** ColumnsSub \(\geq\) 1

- **MatrixSubID** (output_control) .......................................................... matrix \(\mapsto\) handle
  Matrix handle of the sub-matrix.

If the parameters are valid, the operator get_sub_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### **get_value_matrix** ( : : MatrixID, Row, Column : Value )

Return one ore more elements of a matrix.

The operator get_value_matrix returns the values of one ore more elements of the Matrix as a tuple of floating point numbers. The Matrix is given by the matrix handle MatrixID. The row coordinates of the elements of the Matrix are determined by the tuple Row, the column coordinates by the tuple Column.

Example:

Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix}
\]
Row = [0, 2, 1] \hspace{1cm} Column = [1, 0, 3]

\[\mapsto \text{Value} = [1.0, -9.0, 6.0]\]

**Parameters**

- **MatrixID** (input_control) .......................................................... matrix \(\mapsto\) handle
  Matrix handle of the input matrix.

- **Row** (input_control) ........................................................... integer(-array) \(\mapsto\) integer
  Row numbers of matrix elements to be returned.
  **Default value:** 0
  **Suggested values:** Row \(\in\) \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** Row \(\geq\) 0

- **Column** (input_control) ........................................................... integer(-array) \(\mapsto\) integer
  Column numbers of matrix elements to be returned.
  **Default value:** 0
  **Suggested values:** Column \(\in\) \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** Column \(\geq\) 0

- **Value** (output_control) .......................................................... real(-array) \(\mapsto\) real
  Values of indicated matrix elements.
19.1. ACCESS

Result

If the parameters are valid, the operator `get_value_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_matrix`

Possible Successors

`clear_matrix`

See also

`set_value_matrix`

Module

Foundation

**set_diagonal_matrix** (*: : MatrixID, VectorID, Diagonal : )

Set the diagonal elements of a matrix.

The operator `set_diagonal_matrix` overwrites the diagonal elements of the `Matrix` with the elements of the `Matrix` `Vector`. The matrices are defined by their matrix handles `MatrixID` and `VectorID`. The matrix `Vector` must have one column and one row, one column and `n` rows, or one row and `n` columns. The number of elements to be set in the `Matrix` (see below). If the matrix `Vector` has one column and one row, i.e., the matrix has one value, each element of the diagonal of the `Matrix` is overwritten by this value. Otherwise, the diagonal is overwritten by the elements of the `Matrix` `Vector`.

If `Diagonal` = 0, the main diagonal of the `Matrix` is overwritten. The number `n` = min(number of rows of `Matrix`, number of columns of `Matrix`).

Example 1:

Matrix = 
\[
\begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Vector = 
\[
\begin{bmatrix}
3.0 & 7.0 & 1.0
\end{bmatrix}
\]

\[ \rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 7.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 1.0 & 0.0 \end{bmatrix} \]

Example 2:

Matrix = 
\[
\begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Vector = 
\[
\begin{bmatrix}
3.0
\end{bmatrix}
\]

\[ \rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 3.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 3.0 & 0.0 \end{bmatrix} \]

If `Diagonal` is positive, the `Diagonal`-th super-diagonal of `Matrix` is overwritten. For the example 1 the number `n` = min(number of rows of `Matrix`, parameter `Diagonal`). For the example 2 the number `n` = min(number of rows of `Matrix`, number of columns of `Matrix`).

Example 1:
Matrix = \[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  Vector = [ -2.0  6.0 ]  Diagonal = 2

\[\rightarrow \quad \text{Matrix} = \begin{bmatrix}
0 & 0 & -2.0 & 0 & 0 \\
0 & 0 & 0 & 6.0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}\]

Example 2:

Matrix = \[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  Vector = [ -2.0 ]  Diagonal = 2

\[\rightarrow \quad \text{Matrix} = \begin{bmatrix}
0 & 0 & -2.0 & 0 & 0 \\
0 & 0 & 0 & 0 & -2.0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}\]

If Diagonal is negative, the Diagonal-th sub-diagonal of Matrix is overwritten. For the example 1 the number \(n = \min(\text{number of columns of Matrix, parameter Diagonal})\). For the example 2 the number \(n = \min(\text{number of rows of Matrix, number of columns of Matrix})\).

Example 1:

Matrix = \[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  Vector = [ -5.0 -4.0 ]  Diagonal = -1

\[\rightarrow \quad \text{Matrix} = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
-5.0 & 0 & 0 & 0 & 0 \\
0 & -4.0 & 0 & 0 & 0 \\
\end{bmatrix}\]

Example 2:

Matrix = \[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  Vector = [ -5 ]  Diagonal = -1

\[\rightarrow \quad \text{Matrix} = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
-5.0 & 0 & 0 & 0 & 0 \\
0 & -5.0 & 0 & 0 & 0 \\
\end{bmatrix}\]

### Parameters

- **MatrixID** (input_control)  
  Matrix handle of the input matrix.
- **VectorID** (input_control)  
  Matrix handle containing the diagonal elements to be set.
- **Diagonal** (input_control)  
  Position of the diagonal. 
  Default value: 0 
  Suggested values: Diagonal \(\in \{-20, -10, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}\)

### Result

If the parameters are valid, the operator `set_diagonal_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• **MatrixID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Module**

*Foundation*

---

### `set_full_matrix` ( : : MatrixID, Values : )

*Set all values of a matrix.*

The operator `set_full_matrix` sets all elements of the input `Matrix` defined by the matrix handle `MatrixID`. The values of the parameter `Values` can be a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically. The parameter `Values` must contain all values in a row-major order, i.e., stored line by line. In addition, the number of elements in `Values` must be 1 or identical to the number of all elements of the matrix.

**Note:** The same result can be reached with the operator `create_matrix`. The advantage by using the operator `set_full_matrix` is to recycle a matrix that is no longer needed. Thus, the runtime of the operation takes fewer time.

**Example 1:**

Matrix = \[
\begin{bmatrix}
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Values = \[3, 1, -2, -5, 7, 2, -9, -4, 1\]

\[\rightarrow\] Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\]

**Example 2:**

Matrix = \[
\begin{bmatrix}
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Values = \[7\]

\[\rightarrow\] Matrix = \[
\begin{bmatrix}
7.0 & 7.0 & 7.0 \\
7.0 & 7.0 & 7.0 \\
7.0 & 7.0 & 7.0
\end{bmatrix}
\]

---

**Parameters**

- **MatrixID** (input_control) ................................. matrix \(~\) handle
  Matrix handle of the input matrix.
- **Values** (input_control) ................................. number(-array) \(~\) real / integer
  Values to be set.
**Result**

If the parameters are valid, the operator `set_full_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixID**

`get_full_matrix`

**Module**

`Foundation`

---

**set_sub_matrix** ( : : MatrixID, MatrixSubID, Row, Column : )

Set a sub-matrix of a matrix.

The operator `set_sub_matrix` overwrites a part of the Matrix with the matrix MatrixSub. The input matrices are defined by the matrix handles `MatrixID` and `MatrixSubID`. The parameters `Row` and `Column` determine the position of the upper left corner of the sub-matrix `MatrixSub` in `Matrix`.

Example:

\[
\begin{bmatrix}
3.0 & 0.0 & 9.0 & 1.0 \\
-5.0 & 3.0 & 1.0 & 6.0 \\
-9.0 & 0.0 & 1.0 & -1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
1.0 & -2.0 \\
7.0 & 2.0 \\
-4.0 & 1.0
\end{bmatrix}
\]

\[
\rightarrow \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix}
\]

**Attention**

The conditions \(0 \leq \text{Row} < \text{size of matrix Matrix in the row direction}, \text{Row} + \text{size of matrix MatrixSub in the row direction} \leq \text{size of matrix Matrix in the row direction}, 0 \leq \text{Column} < \text{size of Matrix in the column direction}, \text{Column} + \text{size of matrix MatrixSub in the columns direction} \leq \text{size of Matrix in the column direction} \) must be satisfied.

**Parameters**

- **MatrixID** (input_control) .......................................................... matrix \(\rightarrow\) handle
  Matrix handle of the input matrix.
- **MatrixSubID** (input_control) ...................................................... matrix \(\rightarrow\) handle
  Matrix handle of the input sub-matrix.
- **Row** (input_control) .............................................................. integer \(\rightarrow\) integer
  Upper row position of the sub-matrix in the matrix.

**Default value:** 0

**Suggested values:** `Row \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}`

**Restriction:** `Row >= 0`
19.1. **ACCESS**

**Column** (input_control) ......................................................... integer ~ integer

Left column position of the sub-matrix in the matrix.

**Default value:** 0

**Suggested values:** Column \( \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\} \)

**Restriction:** Column \( \geq 0 \)

--- **Result**

If the parameters are valid, the operator `set_sub_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

--- **Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

### `set_value_matrix` (: : MatrixID, Row, Column, Value : )

Set one or more elements of a matrix.

The operator `set_value_matrix` sets the values of the elements of the input `Matrix` at the positions (Row,Column) to the values specified by `Value`. The values can be a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically. The number of values of `Value` must match the number of elements of `Row` and `Column`. In addition, the conditions \( 0 \leq \text{Row} < \text{size of Matrix} \) in the row direction and \( 0 \leq \text{Column} < \text{size of Matrix} \) in the column direction must be satisfied. The `Matrix` is defined by the matrix handle `MatrixID`.

Example:

\[
\begin{bmatrix}
3.0 & 0.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & -2.0 \\
8.0 & -4.0 & 1.0 & -1.0
\end{bmatrix}
\]

\( \Rightarrow \) \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix}
\]
Parameters

▷ MatrixID (input_control) .......................................................... matrix → handle
Matrix handle of the input matrix.

▷ Row (input_control) .......................................................... integer(-array) → integer
Row numbers of the matrix elements to be modified.
  
  Default value: 0
  
  Suggested values: Row ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
  
  Restriction: Row ≥ 0

▷ Column (input_control) ...................................................... integer(-array) → integer
Column numbers of the matrix elements to be modified.
  
  Default value: 0
  
  Suggested values: Column ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
  
  Restriction: Column ≥ 0

▷ Value (input_control) ....................................................... number(-array) → real / integer
Values to be set in the indicated matrix elements.
  
  Default value: 0
  
  Suggested values: Value ∈ {0, 1, -1}

Result

If the parameters are valid, the operator set_value_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

19.2 Arithmetic

abs_matrix ( : : MatrixID : MatrixAbsID )

Compute the absolute values of the elements of a matrix.

The operator abs_matrix computes the absolute values of all elements of the input Matrix given by the matrix handle MatrixID. A new matrix MatrixAbs is generated with the result. The operator returns the matrix handle MatrixAbsID of the matrix MatrixAbs. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[
\text{MatrixAbs}_{ij} = |\text{Matrix}_{ij}|
\]

Example:
Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\] → MatrixAbs = \[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Foundation

---

### add_matrix ( : : MatrixAID, MatrixBID : MatrixSumID )

Add two matrices.

The operator `add_matrix` computes the sum of the input matrices `MatrixA` and `MatrixB` given by the matrix handles `MatrixAID` and `MatrixBID`. Both matrices must have identical dimensions. A new matrix `MatrixSum` is generated with the result. The operator returns the matrix handle `MatrixSumID` of the matrix `MatrixSum`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{MatrixSum} = \text{MatrixA} + \text{MatrixB}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix} \quad \begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 5.0 \\
2.0 & -4.0 & 7.0
\end{bmatrix}
\]

\rightarrow \quad \begin{bmatrix}
5.0 & 9.0 & -5.0 \\
-9.0 & 6.0 & 7.0 \\
-7.0 & -8.0 & 8.0
\end{bmatrix}

**Parameters**

- **MatrixAID** (input_control) : Matrix handle of the input matrix A.
- **MatrixBID** (input_control) : Matrix handle of the input matrix B.
- **MatrixSumID** (output_control) : Matrix handle with the sum of the input matrices.

**Result**

If the parameters are valid, the operator `add_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

add_matrix_mod ( : : MatrixAID, MatrixBID : )

Add two matrices.

The operator add_matrix_mod computes the sum of the input matrices MatrixA and MatrixB given by the matrix handles MatrixAID and MatrixBID. Both matrices must have identical dimensions. The input matrix MatrixA is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[
\text{MatrixA} = \text{MatrixA} + \text{MatrixB}.
\]

Example:

\[
\begin{pmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{pmatrix}
\]

\[
\begin{pmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 5.0 \\
2.0 & -4.0 & 7.0
\end{pmatrix}
\]

\[
\Rightarrow \text{MatrixA} = \begin{pmatrix}
5.0 & 9.0 & -5.0 \\
-9.0 & 6.0 & 7.0 \\
-7.0 & -8.0 & 8.0
\end{pmatrix}
\]

Parameters

▷ MatrixAID (input_control) ................................................................. matrix \sim handle
Matrix handle of the input matrix A.

▷ MatrixBID (input_control) ................................................................. matrix \sim handle
Matrix handle of the input matrix B.

Result

If the parameters are valid, the operator add_matrix_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• MatrixAID
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Foundation

\textbf{div_element_matrix} ( : : MatrixAID, MatrixBID : MatrixDivID )

Divide matrices element-by-element.

The operator \textit{div_element_matrix} divides the two matrices \textit{MatrixA} and \textit{MatrixB} element-by-element. The matrices are given by the matrix handles \textit{MatrixAID} and \textit{MatrixBID}. It is required that both input matrices have identical dimensions. The new created output \textit{MatrixDiv} contains the result. The operator returns the matrix handle \textit{MatrixDivID} of the matrix \textit{MatrixDiv}. Access to the elements of the matrix is possible e.g. with the operator \textit{get_full_matrix}. The formula for the calculation of the result is:

\[
\text{MatrixDiv}_{ij} = \frac{\text{MatrixA}_{ij}}{\text{MatrixB}_{ij}}.
\]

Example:

\[
\begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0
\end{bmatrix}
\quad \begin{bmatrix}
-2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 4.0 \\
-2.0 & -4.0 & 2.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
2.0 & 1.0 & 0.0 \\
1.5 & -7.0 & 0.5 \\
4.5 & -1.0 & 0.5
\end{bmatrix}
\]

Parameters
- \textbf{MatrixAID} (input_control) \hspace{1cm} \textbf{MatrixBID} (input_control) \hspace{1cm} \textbf{MatrixDivID} (output_control)

\begin{itemize}
\item Matrix handle of the input matrix A.
\item Matrix handle of the input matrix B.
\item Matrix handle with the divided values of input matrices.
\end{itemize}

Result
- If the parameters are valid, the operator \textit{div_element_matrix} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
Divide matrices element-by-element.

The operator \texttt{div\_element\_matrix\_mod} divides the two matrices \texttt{MatrixA} and \texttt{MatrixB} element-by-element. The matrices are given by the matrix handles \texttt{MatrixAID} and \texttt{MatrixBID}. It is required that both input matrices have identical dimensions. The input matrix \texttt{MatrixA} is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator \texttt{get\_full\_matrix}. The formula for the calculation of the result is:

\[ \text{MatrixA}_{ij} = \frac{\text{MatrixA}_{ij}}{\text{MatrixB}_{ij}}. \]

Example:

\[
\begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0 \\
\end{bmatrix}
\]

\[
\rightarrow \begin{bmatrix}
2.0 & 1.0 & 0.0 \\
1.5 & -7.0 & 0.5 \\
4.5 & -1.0 & 0.5 \\
\end{bmatrix}
\]

\begin{itemize}
  \item \texttt{MatrixAID} (input\_control) \hspace{1cm} \texttt{MatrixBID} (input\_control)
  \item \texttt{MatrixAID} (input\_control)
  \item \texttt{MatrixBID} (input\_control)
\end{itemize}

If the parameters are valid, the operator \texttt{div\_element\_matrix\_mod} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

\begin{itemize}
  \item Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  \item Multithreading scope: global (may be called from any thread).
  \item Processed without parallelization.
\end{itemize}

This operator modifies the state of the following input parameter:

\begin{itemize}
  \item \texttt{MatrixAID}
\end{itemize}

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
Possible Successors
get_full_matrix, get_value_matrix

Alternatives
div_element_matrix

See also
mult_element_matrix, mult_element_matrix_mod, scale_matrix, scale_matrix_mod

Module
Foundation

invert_matrix ( : : MatrixID, MatrixType, Epsilon : MatrixInvID )

Invert a matrix.

The operator invert_matrix computes the inverse of the Matrix defined by the matrix handle MatrixID. A new matrix MatrixInv is generated with the result and the matrix handle MatrixInvID of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

For Epsilon = 0, the inverse is computed. The type of the Matrix can be selected via MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'tridiagonal' for tridiagonal, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices.

Example 1:

Matrix = 
\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
5.0 & 5.0 & 7.0
\end{bmatrix}
\]
MatrixType = 'general' Epsilon = 0

\rightarrow MatrixInv = 
\[
\begin{bmatrix}
-1.25 & 1.50 & -0.75 \\
-0.50 & 2.00 & -1.50 \\
1.25 & -2.50 & 1.75
\end{bmatrix}
\]

Example 2:

Matrix = 
\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 2.0 & 6.0 \\
0 & 0 & 10.0
\end{bmatrix}
\]
MatrixType = 'upper_triangular' Epsilon = 0

\rightarrow MatrixInv = 
\[
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10
\end{bmatrix}
\]

Example 3:

Matrix = 
\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 0 & 10.0 \\
0 & 2.0 & 6.0
\end{bmatrix}
\]
MatrixType = 'permuted_upper_triangular' Epsilon = 0

\rightarrow MatrixInv = 
\[
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10
\end{bmatrix}
\]

For Epsilon > 0, the pseudo inverse is computed using a singular value decomposition (SVD). During the computation, all singular values less than the value Epsilon x the largest singular value are set to 0. For these values no internal division is done to prevent a division by zero. If a square matrix is computed with the SVD algorithm the computation takes more time. The type of the matrix must be set to MatrixType = 'general'.

Example:
Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 5.0 \\
-5.0 & 7.0 & 2.0 & -6.0 \\
-9.0 & -4.0 & 1.0 & 4.0
\end{bmatrix}
\]  \quad \text{MatrixType} = 'general'  \quad \text{Epsilon} = 2.2204\times10^{-16}

\rightarrow \quad \text{MatrixInv} = \[
\begin{bmatrix}
-0.0021 & -0.0482 & -0.0813 \\
0.1435 & 0.1137 & -0.0137 \\
-0.0519 & -0.0015 & 0.0028 \\
0.1518 & 0.0056 & 0.0526
\end{bmatrix}
\]

Note: The relative accuracy of the floating point representation of the used data type (double) is Epsilon = 2.2204e-16.

It should be also noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

Attention

For MatrixType = ‘symmetric’, ‘positive_definite’, or ‘upper_triangular’ the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixType = ‘lower_triangular’ the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For MatrixType = ‘tridiagonal’, only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

Parameters

\begin{itemize}
  \item \textbf{MatrixID} (input_control) \quad \text{matrix} \mapsto \text{handle} \\
  \quad \text{Matrix handle of the input matrix.}
  \item \textbf{MatrixType} (input_control) \quad \text{string} \mapsto \text{string} \\
  \quad \text{The type of the input matrix.} \\
  \quad \text{Default value:} 'general' \\
  \quad \text{List of values:} \text{MatrixType} \in \{'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'\}
  \item \textbf{Epsilon} (input_control) \quad \text{real} \mapsto \text{real} \\
  \quad \text{Type of inversion.} \\
  \quad \text{Default value:} 0.0 \\
  \quad \text{Suggested values:} \text{Epsilon} \in [0.0, 2.2204\times10^{-16}]
  \item \textbf{MatrixInvID} (output_control) \quad \text{matrix} \mapsto \text{handle} \\
  \quad \text{Matrix handle with the inverse matrix.}
\end{itemize}

Result

If the parameters are valid, the operator \textbf{invert_matrix} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

\begin{itemize}

HALCON 20.05.0.0
inv_matrix_mod ( : : MatrixID, MatrixType, Epsilon : )

Invert a matrix.

The operator inv_matrix_mod computes the inverse of the Matrix defined by the matrix handle MatrixID. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

For Epsilon = 0, the inverse is computed. The type of the Matrix can be selected via MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'tridiagonal' for tridiagonal, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices.

Example 1:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
5.0 & 5.0 & 7.0
\end{bmatrix}
\]

MatrixType = 'general'  Epsilon = 0

\[
\rightarrow
\begin{bmatrix}
-1.25 & 1.50 & -0.75 \\
-0.50 & 2.00 & -1.50 \\
1.25 & -2.50 & 1.75
\end{bmatrix}
\]

Example 2:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 2.0 & 6.0 \\
0 & 0 & 10.0
\end{bmatrix}
\]

MatrixType = 'upper_triangular'  Epsilon = 0

\[
\rightarrow
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10
\end{bmatrix}
\]

Example 3:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 0 & 10.0 \\
0 & 2.0 & 6.0
\end{bmatrix}
\]

MatrixType = 'permuted_upper_triangular'  Epsilon = 0

\[
\rightarrow
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10
\end{bmatrix}
\]

For Epsilon > 0, the pseudo inverse is computed using a singular value decomposition (SVD). During the computation, all singular values less than the value Epsilon \times \text{the largest singular value} are set to 0. For these values no internal division is done to prevent a division by zero. If a square matrix is computed with the SVD algorithm the computation takes more time. The type of the matrix must be set to MatrixType = 'general'.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 5.0 \\
-5.0 & 7.0 & 2.0 & -6.0 \\
-9.0 & -4.0 & 1.0 & 4.0
\end{bmatrix}
\]

MatrixType = 'general'  Epsilon = 2.2204e-16
Note: The relative accuracy of the floating point representation of the used data type (double) is $\text{Epsilon} = 2.2204e^{-16}$.

It should be also noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

Attention
For $\text{MatrixType} =$ ‘symmetric’, ‘positive_definite’, or ‘upper_triangular’ the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For $\text{MatrixType} =$ ‘lower_triangular’ the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For $\text{MatrixType} =$ ‘tridiagonal’, only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

invert_matrix_mod modifies the content of an already existing matrix.

Parameters

- $\text{MatrixID}$ (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix $\mapsto$ handle
  - Matrix handle of the input matrix.

- $\text{MatrixType}$ (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string $\mapsto$ string
  - The type of the input matrix.
  - Default value: ‘general’

- $\text{Epsilon}$ (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real $\mapsto$ real
  - Type of inversion.
  - Default value: 0.0
  - Suggested values: $\text{Epsilon} \in \{0.0, 2.2204e^{-16}\}$

Result

If the parameters are valid, the operator invert_matrix_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

\[ \text{mult}\_element\_matrix} ( : : \text{MatrixAID}, \text{MatrixBID} : \text{MatrixMultID} ) \]

Multiply matrices element-by-element.

The operator \( \text{mult}\_element\_matrix \) multiplies the two matrices \( \text{MatrixA} \) and \( \text{MatrixB} \) element-by-element. The matrices are defined by the matrix handles \( \text{MatrixAID} \) and \( \text{MatrixBID} \). It is required that both input matrices have identical dimensions. A new matrix \( \text{MatrixMult} \) is generated with the result. The operator returns the matrix handle \( \text{MatrixMultID} \) of the matrix \( \text{MatrixMult} \). Access to the elements of the matrix is possible e.g. with the operator \( \text{get}\_full\_matrix \). The formula for the calculation of the result is:

\[
\text{MatrixMult}_{ij} = \text{MatrixA}_{ij} \cdot \text{MatrixB}_{ij}.
\]

Example:

\[
\begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 4.0 \\
-2.0 & -4.0 & 2.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
8.0 & 64.0 & 0.0 \\
24.0 & -7.0 & 8.0 \\
18.0 & -16.0 & 2.0
\end{bmatrix}
\]

Parameters

- \( \text{MatrixAID} \) (input_control) \( \ldots \text{matrix} \ldots \text{handle} \)
- \( \text{MatrixBID} \) (input_control) \( \ldots \text{matrix} \ldots \text{handle} \)
- \( \text{MatrixMultID} \) (output_control) \( \ldots \text{matrix} \ldots \text{handle} \)

Result

If the parameters are valid, the operator \( \text{mult}\_element\_matrix \) returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

**mult_element_matrix_mod** ( : : MatrixAID, MatrixBID : )

Multiply matrices element-by-element.

The operator **mult_element_matrix_mod** multiplies the two matrices **MatrixA** and **MatrixB** element-by-element. The matrices are defined by the matrix handles **MatrixAID** and **MatrixBID**. It is required that both input matrices have identical dimensions. The input matrix **MatrixA** is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator **get_full_matrix**. The formula for the calculation of the result is:

\[ MatrixA_{ij} = MatrixA_{ij} \cdot MatrixB_{ij}. \]

Example:

\[
\begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0
\end{bmatrix}
\begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 4.0 \\
-2.0 & -4.0 & 2.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
8.0 & 64.0 & 0.0 \\
24.0 & -7.0 & 8.0 \\
18.0 & -16.0 & 2.0
\end{bmatrix}
\]

**Parameters**

- **MatrixAID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix  ~> handle
  Matrix handle of the input matrix A.

- **MatrixBID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix  ~> handle
  Matrix handle of the input matrix B.

**Result**

If the parameters are valid, the operator **mult_element_matrix_mod** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixAID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Module**

Foundation
Multiply two matrices.

The operator `mult_matrix` computes the product of the input matrices `MatrixA` and `MatrixB` defined by the matrix handles `MatrixAID` and `MatrixBID`. A new matrix `MatrixMult` is generated with the result. The operator returns the matrix handle `MatrixMultID` of the matrix `MatrixMult`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. If desired, one or both input matrices will be transposed for the multiplication.

The type of multiplication can be selected via `MultType`:

'`AB`': The matrices `MatrixA` and `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixMult} = \text{MatrixA} \times \text{MatrixB}. \]

The number of columns of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

\[
\text{MatrixA} = \begin{bmatrix}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{bmatrix}
\]
\[
\text{MatrixB} = \begin{bmatrix}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{bmatrix}
\]

\[ \rightarrow \text{MatrixMult} = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

'`ATB`': The matrix `MatrixA` will be transposed. The matrix `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixMult} = \text{MatrixA}^T \times \text{MatrixB}. \]

The number of rows of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

\[
\text{MatrixA} = \begin{bmatrix}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{bmatrix}
\]
\[
\text{MatrixB} = \begin{bmatrix}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{bmatrix}
\]

\[ \rightarrow \text{MatrixMult} = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

'`ABT`': The matrix `MatrixA` will not be transposed. The matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixMult} = \text{MatrixA} \times \text{MatrixB}^T. \]

The number of columns of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

\[
\text{MatrixA} = \begin{bmatrix}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{bmatrix}
\]
\[
\text{MatrixB} = \begin{bmatrix}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{bmatrix}
\]

\[ \rightarrow \text{MatrixMult} = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]
'ATBT': The matrix MatrixA and the matrix MatrixB will be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixMult} = \text{MatrixA}^T \cdot \text{MatrixB}^T. \]

The number of rows of the matrix MatrixA must be identical to the number of columns of the matrix MatrixB.

Example:

\[
\begin{align*}
\text{MatrixA} &= \begin{bmatrix} 3.0 & 2.0 & -3.0 \\ -3.0 & -5.0 & 2.0 \end{bmatrix} \\
\text{MatrixB} &= \begin{bmatrix} 3.0 & 2.0 \\ -3.0 & -1.0 \\ 1.0 & -2.0 \\ 1.0 & -1.0 \end{bmatrix}
\end{align*}
\]

\[ \rightarrow \text{MatrixMult} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix} \]
Multiply two matrices.

The operator `mult_matrix` computes the product of the input matrices `MatrixA` and `MatrixB` defined by the matrix handles `MatrixAID` and `MatrixBID`. The input matrix `MatrixA` is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. If desired, one or both input matrices will be transposed for the multiplication.

The type of multiplication can be selected via `MultType`:

`'AB'`: The matrices `MatrixA` and `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

\[
MatrixA = MatrixA \cdot MatrixB.
\]

The number of columns of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

\[
MatrixA = \begin{bmatrix}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{bmatrix}
\]

\[
MatrixB = \begin{bmatrix}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{bmatrix}
\]

\[
\rightarrow MatrixA = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

`'ATB'`: The matrix `MatrixA` will be transposed. The matrix `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

\[
MatrixA = (MatrixA)^T \cdot MatrixB.
\]

The number of rows of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

\[
MatrixA = \begin{bmatrix}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{bmatrix}
\]

\[
MatrixB = \begin{bmatrix}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{bmatrix}
\]

\[
\rightarrow MatrixA = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

`'ABT'`: The matrix `MatrixA` will not be transposed. The matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

\[
MatrixA = MatrixA \cdot (MatrixB)^T.
\]

The number of columns of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

\[
MatrixA = \begin{bmatrix}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{bmatrix}
\]

\[
MatrixB = \begin{bmatrix}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{bmatrix}
\]

\[
\rightarrow MatrixA = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]
'ATBT': The matrix MatrixA and the matrix MatrixB will be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixA} = \text{MatrixA}^T \cdot \text{MatrixB}^T. \]

The number of rows of the matrix MatrixA must be identical to the number of columns of the matrix MatrixB.

Example:

MatrixA = \[
\begin{bmatrix}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{bmatrix}
\]
MatrixB = \[
\begin{bmatrix}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{bmatrix}
\]

\[ \Rightarrow \text{MatrixA} = \[
\begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

Parameters

`pow_element_matrix_mod` ( : : MatrixID, MatrixExpID : )

Compute the power functions of the elements of a matrix.
The operator `pow_element_matrix_mod` computes the power of all elements of the input `Matrix` with the elements of the input matrix `MatrixExp`. The input matrices `Matrix` and `MatrixExp` are defined by the matrix handles `MatrixID` and `MatrixExpID`. Both matrices must have identical dimensions. The input `Matrix` is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[ \text{Matrix}_{ij} = \text{Matrix}_{ij}^{\text{MatrixExp}_{ij}}. \]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
1.0 & 2.0 & 2.0 \\
2.0 & 0.0 & 3.0 \\
0.5 & 3.0 & 1.0
\end{bmatrix}
\]

\[\rightarrow \begin{bmatrix}
3.0 & 1.0 & 4.0 \\
25.0 & 1.0 & 8.0 \\
3.0 & 64.0 & 1.0
\end{bmatrix}\]

**Parameters**

- `MatrixID` (input_control) ..........................matrix \(\rightsquigarrow\) handle
  Matrix handle of the input matrix of the base.
- `MatrixExpID` (input_control) ..........................matrix \(\rightsquigarrow\) handle
  Matrix handle of the input matrix with exponents.

**Result**

If the parameters are valid, the operator `pow_element_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

**Module**

- `pow_matrix ( : : MatrixID, MatrixType, Power : : MatrixPowID )`

*Compute the power functions of a matrix.*

The operator `pow_matrix` computes the power of the input `Matrix` by a constant value. The input `Matrix` is given by the matrix handle `MatrixID`. The power value is given by the parameter `Power`. A new matrix
MatrixPow is generated with the result. The operator returns the matrix handle MatrixPowID of the matrix MatrixPow. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

The type of the Matrix can be selected via MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices. The formula for the calculation of the result is:

\[ \text{MatrixPow} = \text{MatrixPower}. \]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]

\[\text{Power} = \begin{bmatrix} 2.0 \end{bmatrix} \]

\[\text{MatrixType} = 'general'\]

\[
\begin{bmatrix}
32.0 & 18.0 & 10.0 \\
68.0 & 62.0 & 26.0 \\
56.0 & 41.0 & 27.0
\end{bmatrix}
\]

Attention

For MatrixType = 'symmetric', 'positive_definite', or 'upper_triangular' the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixType = 'lower_triangular' the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

---

Parameters

- **MatrixID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle of the input matrix.

- **MatrixType** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string
  - The type of the input matrix.
  - Default value: 'general'
  - List of values: MatrixType ∈ {'general', 'symmetric', 'positive_definite', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}

- **Power** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . number／real／integer
  - The power.
  - Default value: 2.0
  - Suggested values: Power ∈ {0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}

- **MatrixPowID** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle with the raised powered matrix.

---

Result

If the parameters are valid, the operator pow_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

pow_matrix_mod ( : : MatrixID, MatrixType, Power : )

Compute the power functions of a matrix.

The operator pow_matrix_mod computes the power of the input Matrix by a constant value. The input Matrix is given by the matrix handle MatrixID. The power value is given by the parameter Power. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

The type of the Matrix can be selected via MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices. The formula for the calculation of the result is:

Matrix = Matrix^Power.

Example:

Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]

Power = \[
\begin{bmatrix}
2.0
\end{bmatrix}
\]

MatrixType = 'general'

\[
\Rightarrow \text{Matrix} = \begin{bmatrix}
32.0 & 18.0 & 10.0 \\
68.0 & 62.0 & 26.0 \\
56.0 & 41.0 & 27.0
\end{bmatrix}
\]

Attention

For MatrixType = 'symmetric', 'positive_definite', or 'upper_triangular' the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixType = 'lower_triangular' the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

pow_matrix_mod modifies the content of an already existing matrix.

Parameters

- **MatrixID** (input_control) 
  Matrix handle of the input matrix.
- **MatrixType** (input_control) 
  The type of the input matrix.
  Default value: 'general'
  List of values: MatrixType ∈ {'general', 'symmetric', 'positive_definite', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- **Power** (input_control) 
  The power.
  Default value: 2.0
  Suggested values: Power ∈ \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}

Result

If the parameters are valid, the operator pow_matrix_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

HALCON 20.05.0.0
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

**pow_scalar_element_matrix** ( : : MatrixID, Power : MatrixPowID )

*Compute the power functions of the elements of a matrix.*

The operator `pow_scalar_element_matrix` computes the power of all elements of the input `Matrix` by a constant value. The input `Matrix` is given by the matrix handle `MatrixID`. The power value is given by the parameter `Power`. A new matrix `MatrixPow` is generated with the result. The operator returns the matrix handle `MatrixPowID` of the matrix `MatrixPow`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{MatrixPow}_{ij} = \text{Matrix}_{ij}^{\text{Power}}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]

\[
\text{Power} = [2.0]
\]

\[
\rightarrow \begin{bmatrix}
9.0 & 1.0 & 4.0 \\
25.0 & 49.0 & 4.0 \\
81.0 & 16.0 & 1.0
\end{bmatrix}
\]

**Parameters**

- **MatrixID** (input_control)  
  Matrix handle of the input matrix.

- **Power** (input_control)  
  The power.

  Default value: 2.0

  Suggested values: Power ∈ \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}

- **MatrixPowID** (output_control)  
  Matrix handle with the raised power of the input matrix.

**Result**

If the parameters are valid, the operator `pow_scalar_element_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

pow_scalar_element_matrix_mod ( : : MatrixID, Power : )

Compute the power functions of the elements of a matrix.

The operator \texttt{pow\_scalar\_element\_matrix\_mod} computes the power of all elements of the input \texttt{Matrix} by a constant value. The input \texttt{Matrix} is given by the matrix handle \texttt{MatrixID}. The power value is given by the parameter \texttt{Power}. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator \texttt{get\_full\_matrix}. The formula for the calculation of the result is:

\[
\text{Matrix}_{ij} = \text{Matrix}_{ij}^{\text{Power}}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\quad \text{Power} = \begin{bmatrix} 2.0 \end{bmatrix}
\]

\[
\rightarrow \begin{bmatrix}
9.0 & 1.0 & 4.0 \\
25.0 & 49.0 & 4.0 \\
81.0 & 16.0 & 1.0
\end{bmatrix}
\]

Parameters

\begin{itemize}
\item \texttt{MatrixID} (input\_control) \texttt{Matrix handle of the input matrix.}
\item \texttt{Power} (input\_control) \texttt{The power.}
\end{itemize}

Default value: 2.0

Suggested values: \texttt{Power} \in \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}

Result

If the parameters are valid, the operator \texttt{pow\_scalar\_element\_matrix\_mod} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

```cpp
scale_matrix ( : : MatrixID, Factor : : MatrixScaledID )
```

**Scale a matrix.**

The operator `scale_matrix` scales the `Matrix` by a constant factor. The matrix is defined by the matrix handle `MatrixID`. A new matrix `MatrixScaled` is generated with the result. The operator returns the matrix handle `MatrixScaledID`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{MatrixScaled}_{ij} = \text{Factor} \cdot \text{Matrix}_{ij}. 
\]

**Example:**

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-2.0 & 6.0 & 2.0 \\
-5.0 & -4.0 & 1.0
\end{bmatrix} \quad \text{Factor} = 1.5
\]

\[
\rightarrow \quad \text{MatrixScaled} = \begin{bmatrix}
4.5 & 1.5 & -3.0 \\
-3.0 & 9.0 & 3.0 \\
-7.5 & -6.0 & 1.5
\end{bmatrix}
\]

**Parameters**

- **MatrixID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle of the input matrix.

- **Factor** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . number 
  - real / integer
  - Scale factor.
  - Default value: 2.0
  - Suggested values: Factor ∈ \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}

- **MatrixScaledID** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle with the scaled elements.

**Result**

If the parameters are valid, the operator `scale_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

scale_matrix_mod ( : : MatrixID, Factor : )

Scale a matrix.
The operator `scale_matrix` scales the `Matrix` by a constant factor. The matrix is defined by the matrix handle `MatrixID`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
Matrix_{ij} = Factor \cdot Matrix_{ij}.
\]

Example:

\[
Matrix = \begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-2.0 & 6.0 & 2.0 \\
-5.0 & -4.0 & 1.0
\end{bmatrix} \quad \text{Factor} = 1.5
\]

\[
\rightarrow Matrix = \begin{bmatrix}
4.5 & 1.5 & -3.0 \\
-3.0 & 9.0 & 3.0 \\
-7.5 & -6.0 & 1.5
\end{bmatrix}
\]

Parameters

- **MatrixID** (input_control) matrix handle
  - Matrix handle of the input matrix.
- **Factor** (input_control) number
  - Scale factor.
  - Default value: 2.0
  - Suggested values: `Factor ∈ \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}`

Result

If the parameters are valid, the operator `scale_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Module
Foundation

```
solve_matrix ( : : MatrixLHSID, MatrixLHSType, Epsilon, MatrixRHSID : MatrixResultID )
```

Compute the solution of a system of equations.

The operator `solve_matrix` computes the solution of a system of linear equations or of a linear least squares problem. The input matrices `MatrixLHS` and `MatrixRHS` are defined by the matrix handles `MatrixLHSID` and `MatrixRHSID`. The number of rows of matrices `MatrixLHS` and `MatrixRHS` must be identical. The operator returns the matrix handle `MatrixResultID` of the matrix `MatrixResult`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

For linear equation systems, the equations

\[ \text{MatrixLHS} \cdot \text{MatrixResult} = \text{MatrixRHS} \]

are solved. Therefore, the matrix `MatrixLHS` must be a square matrix and the parameter `Epsilon` must be 0.

The type of the matrix `MatrixLHS` can be selected via the parameter `MatrixLHSType`. The following values are supported: ‘general’ for general, ‘symmetric’ for symmetric, ‘positive_definite’ for symmetric positive definite, ‘tridiagonal’ for tridiagonal, ‘upper_triangular’ for upper triangular, ‘permuted_upper_triangular’ for permuted upper triangular, ‘lower_triangular’ for lower triangular, and ‘permuted_lower_triangular’ for permuted lower triangular matrices.

Example:

\[
\begin{bmatrix}
6.0 & 5.0 & 3.0 \\
5.0 & 7.0 & 3.0 \\
3.0 & 3.0 & 4.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
-1.0 & 6.0 \\
3.0 & -3.0 \\
5.0 & 4.0
\end{bmatrix}
\]

`MatrixLHSType = 'positive_definite'`   \[ Epsilon = 0 \]

\[ \rightarrow \text{MatrixResult} = \begin{bmatrix} -2.0 & 3.0 \\ 1.0 & -3.0 \\ 2.0 & 1.0 \end{bmatrix} \]

For linear least squares problems or if `Epsilon` is not 0, the matrix `MatrixLHS` need not be a square matrix. The linear least squares problem is solved using the singular value decomposition (SVD) of the matrix `MatrixLHS` by minimizing

\[ ||\text{MatrixRHS} - \text{MatrixLHS} \cdot \text{MatrixResult}||. \]

All singular values less than the value `Epsilon \times` the largest singular value are set to 0. For these values no internal division is done to prevent a division by zero. Also, the matrix `MatrixLHS` may be rank-deficient. The type of matrix must be selected via `MatrixLHSType = 'general'`.

Example:

MatrixLHS = \[
\begin{bmatrix}
6.0 & 5.0 & 3.0 \\
3.0 & 7.0 & -3.0 \\
5.0 & 12.0 & 4.0 \\
5.0 & 4.0 & 12.0 \\
4.0 & 6.0 & 8.0 \\
\end{bmatrix}
\]

MatrixRHS = \[
\begin{bmatrix}
29.0 \\
10.0 \\
35.0 \\
43.0 \\
25.0 \\
\end{bmatrix}
\]

MatrixLHSType = 'general'  Epsilon = 2.2204e-16

\[
\rightarrow \quad \text{MatrixResult} = \begin{bmatrix} 3.4914 \\ 0.7114 \\ 1.6213 \end{bmatrix}
\]

Note: The relative accuracy of the floating point representation of the used data type (double) is Epsilon = 2.2204e-16.

Attention
For MatrixLHSType = 'symmetric', 'positive_definite', or 'upper_triangular' the upper triangular part of the input MatrixLHS must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixLHSType = 'lower_triangular' the lower triangular part of the input MatrixLHS must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For MatrixLHSType = 'tridiagonal', only the main diagonal, the superdiagonal, and the subdiagonal of the input MatrixLHS are used. The other parts of the matrix are not referenced. If the referenced part of the input MatrixLHS is not of the specified type, an exception is raised.

Parameters

- MatrixLHSID (input_control)  matrix handle
  Matrix handle of the input matrix of the left hand side.
- MatrixLHSType (input_control)  string
  The type of the input matrix of the left hand side.
  Default value: 'general'
  List of values: MatrixLHSType ∈ {'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- Epsilon (input_control)  real
  Type of solving and limitation to set singular values to be 0.
  Default value: 0.0
  Suggested values: Epsilon ∈ {0.0, 2.2204e-16}
- MatrixRHSID (input_control)  matrix handle
  Matrix handle of the input matrix of right hand side.
- MatrixResultID (output_control)  matrix handle
  New matrix handle with the solution.

Result
If the parameters are valid, the operator solve_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

References

Compute the square root values of the elements of a matrix.

The operator sqrt_matrix computes the square root values of all elements of the input Matrix given by the matrix handle MatrixID. A new matrix MatrixSqrt is generated with the result. The operator returns the matrix handle MatrixSqrtID of the matrix MatrixSqrt. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[ \text{MatrixSqrt}_{ij} = \sqrt{\text{Matrix}_{ij}}. \]

Example:

\[
\begin{pmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{pmatrix} \rightarrow
\begin{pmatrix}
1.7321 & 1.0000 & 1.4142 \\
2.2361 & 2.6458 & 1.4142 \\
3.0000 & 2.0000 & 1.0000
\end{pmatrix}
\]

Parameters

- MatrixID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle of the input matrix.
- MatrixSqrtID (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle with the square root values of the input matrix.

Result

If the parameters are valid, the operator sqrt_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Module

sub_matrix ( : : MatrixAID, MatrixBID : MatrixSubID )

Subtract two matrices.

The operator sub_matrix computes the difference of the input matrices MatrixA and MatrixB given by the matrix handles MatrixAID and MatrixBID. Both matrices must have identical dimensions. A new matrix MatrixSub is generated with the result. The operator returns the matrix handle MatrixSubID of the matrix MatrixSub. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[
Matrix_{\text{Sub}} = Matrix_{\text{A}} - Matrix_{\text{B}}.
\]

Example:

\[
\begin{pmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{pmatrix} \quad \begin{pmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 5.0 \\
2.0 & -4.0 & 7.0
\end{pmatrix}
\]
\[
\begin{bmatrix}
1.0 & -7.0 & 1.0 \\
-1.0 & 8.0 & -3.0 \\
-11.0 & 0.0 & -6.0
\end{bmatrix}
\]

Parameters

\( \text{MatrixAID} \) (input_control) \( \text{Matrix handle of the input matrix A.} \)

\( \text{MatrixBID} \) (input_control) \( \text{Matrix handle of the input matrix B.} \)

\( \text{MatrixSubID} \) (output_control) \( \text{Matrix handle with the difference of the input matrices.} \)

Result

If the parameters are valid, the operator \text{sub_matrix} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

The operator \text{sub_matrix_mod} computes the difference of the input matrices \text{MatrixA} and \text{MatrixB} given by the matrix handles \text{MatrixAID} and \text{MatrixBID}. Both matrices must have identical dimensions. The input matrix \text{MatrixA} is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator \text{get_full_matrix}. The formula for the calculation of the result is:

\[
\text{MatrixA} = \text{MatrixA} - \text{MatrixB}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 5.0 \\
2.0 & -4.0 & 7.0
\end{bmatrix}
\]

\[
\rightarrow \qquad \text{MatrixA} =
\begin{bmatrix}
1.0 & -7.0 & 1.0 \\
-1.0 & 8.0 & -3.0 \\
-11.0 & 0.0 & -6.0
\end{bmatrix}
\]
Parameters

- **MatrixAID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle of the input matrix A.
- **MatrixBID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle of the input matrix B.

Result

If the parameters are valid, the operator `sub_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixAID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Alternatives

- `sub_matrix`

See also

- `add_matrix, add_matrix_mod`

Module

**transpose_matrix** ( : : MatrixID : MatrixTransposedID )

Transpose a matrix.

The operator `transpose_matrix` returns the transpose of the input Matrix. The input matrix is defined by the matrix handle `MatrixID`. A new matrix `MatrixTransposed` is generated with the result and the matrix handle `MatrixTransposedID` of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
3.0 & -5.0 & -9.0 \\
1.0 & 7.0 & -4.0 \\
-2.0 & 2.0 & 1.0
\end{bmatrix}
\]

Parameters

- **MatrixID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle of the input matrix.
- **MatrixTransposedID** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle
  - Matrix handle with the transpose of the input matrix.

Result

If the parameters are valid, the operator `transpose_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
19.3. Creation

**clear_matrix** ( : : MatrixID : )

*Free the memory of a matrix.*

The operator `clear_matrix` frees the memory of the matrix `Matrix` given by the matrix handle `MatrixID`. After calling `clear_matrix`, the `Matrix` can no longer be used. The matrix handle `MatrixID` becomes invalid.

**Parameters**

- **MatrixID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix(-array)  heap_handle
  Matrix handle.

**Result**

If the parameters are valid, the operator `clear_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

`create_matrix`

**Module**

Foundation

**copy_matrix** ( : : MatrixID : MatrixCopyID )

*Copy a matrix.*

The operator `copy_matrix` creates the new matrix `MatrixCopy` and copies all elements of the input `Matrix` to this new matrix. The input `Matrix` is defined by the matrix handle `MatrixID`. The operator returns the matrix handle `MatrixCopyID` of the matrix `MatrixCopy`. Access to the elements of the matrix is possible e.g. with

Possible Successors

References

the operator `get_full_matrix`. With this operator a matrix can be saved before the matrix is modified by the operators `set_value_matrix`, `set_full_matrix`, `set_sub_matrix`, or `set_diagonal_matrix`.

Example:

```
Matrix = [ 3.0 1.0 -2.0 ]
         [ -5.0 7.0 2.0 ]
         [ -9.0 -4.0 1.0 ]
→ MatrixCopy = [ 3.0 1.0 -2.0 ]
            [ -5.0 7.0 2.0 ]
            [ -9.0 -4.0 1.0 ]
```

### Parameters

- **MatrixID** (input_control): Matrix handle of the input matrix.
- **MatrixCopyID** (output_control): Matrix handle of the copied matrix.

### Result

If the parameters are valid, the operator `copy_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Successors

`get_full_matrix`, `get_value_matrix`

### Alternatives

`repeat_matrix`

### Module

`Foundation`

---

### `create_matrix` ( : : Rows, Columns, Value : MatrixID )

Create a matrix.

The operator `create_matrix` creates a new `Matrix` with `Rows` rows and `Columns` columns and returns the matrix handle `MatrixID`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The parameter `Value` is a string or a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically.

If `Value = 'identity'`, `Rows` and `Columns` must have the identical values and an identity matrix is created.

Example:

```
Rows = 3  Columns = 3  Value = 'identity'
```

```
Matrix = [ 1 0 0 ]
         [ 0 1 0 ]
         [ 0 0 1 ]
```

If the parameter `Value` contains a single value, all elements of the matrix are filled with this value.

Example:

```
Rows = 3  Columns = 3  Value = 7
```

```
Matrix = [ 7 0 0 ]
         [ 0 7 0 ]
         [ 0 0 7 ]
```
19.3. CREATION

\[ \begin{bmatrix} 7.0 & 7.0 & 7.0 \\ 7.0 & 7.0 & 7.0 \\ 7.0 & 7.0 & 7.0 \end{bmatrix} \]

If \textit{Value} contains as many values as the main diagonal, all elements of the main diagonal are set to the values of the parameter \textit{Value} (i.e., the number of elements in \textit{Value} is identical).

Example:

\[
\text{Rows} = 3 \quad \text{Columns} = 4 \quad \text{Value} = [3, 7, 1]
\]

\[ \begin{bmatrix} 3.0 & 0 & 0 & 0 \\ 0 & 7.0 & 0 & 0 \\ 0 & 0 & 1.0 & 0 \end{bmatrix} \]

It is also possible to set all elements of the matrix with different values. In this case the parameter \textit{Value} must contain all values in a row-major order, i.e., stored line by line. In addition, the number of elements of \textit{Value} must be identical to the number of all elements of the matrix, i.e., \textit{Rows} × \textit{Columns}.

Example:

\[
\text{Rows} = 3 \quad \text{Columns} = 3 \quad \text{Value} = [3, 1, -2, -5, 7, 2, -9, -4, 1]
\]

\[ \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \]

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.

\begin{itemize}

\end{itemize}
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_full_matrix, clear_matrix

Module

repeat_matrix ( : : MatrixID, Rows, Columns : MatrixRepeatedID )

Repeat a matrix.

The operator repeat_matrix creates the new matrix MatrixRepeated and copies all elements of the input Matrix \( n \) times to this new matrix, where \( n = \text{Rows} \cdot \text{Columns} \). The new matrix has dimensions Rows \( \times \) rows of the input Matrix and Columns \( \times \) columns of the input Matrix. The input Matrix is defined by the matrix handle MatrixID. The operator returns the matrix handle MatrixRepeatedID of the matrix MatrixRepeated. Access to the elements of the matrix is possible e.g., with the operator get_full_matrix.

Example:

\[
\begin{bmatrix}
3.0 & -1.0 & -2.0 \\
-5.0 & 7.0 & 2.0
\end{bmatrix}
\]

\[\rightarrow\]

Rows = 2

Columns = 3

\[
\begin{bmatrix}
3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 \\
3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0
\end{bmatrix}
\]

Parameters

▷ MatrixID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix ↦ handle

Matrix handle of the input matrix.

▷ Rows (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer ↦ integer

Number of copies of input matrix in row direction.

Default value: 2

Suggested values: Rows \( \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20\} \)

Restriction: Rows \( \geq 1 \)

▷ Columns (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer ↦ integer

Number of copies of input matrix in column direction.

Default value: 2

Suggested values: Columns \( \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20\} \)

Restriction: Columns \( \geq 1 \)

▷ MatrixRepeatedID (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix ↦ handle

Matrix handle of the repeated copied matrix.

Result

If the parameters are valid, the operator repeat_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
19.4 Decomposition

```
def decompose_matrix ( : : MatrixID, MatrixType : Matrix1ID, Matrix2ID )
Decompose a matrix.
The operator decompose_matrix decomposes the square input Matrix given by the matrix handle MatrixID. The results are stored in two generated matrices Matrix1 and Matrix2. The operator returns the matrix handles Matrix1ID and Matrix2ID. Access to the elements of the matrices is possible e.g. with the operator get_full_matrix.

The type of the input Matrix can be selected via the parameter MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, and 'tridiagonal' for tridiagonal matrices.

The decomposition MatrixType = 'general' or 'tridiagonal' is a LU factorization (Lower/Upper) with the form

Matrix = Matrix1 * Matrix2.

The output Matrix1 is a lower triangular matrix with unit diagonal elements and interchanged rows. The output Matrix2 is an upper triangular matrix.

Example for a factorization of a general matrix:

Matrix = [ [ 5.0, -3.0, 1.0 ], [ 0.0, 2.0, -1.0 ], [ -5.0, -1.0, 5.0 ] ]

→ Matrix1 = [ [ 1, 0, 0 ], [ 0.0, -0.5, 1 ], [ -1.0, 1, 0 ] ]
Matrix2 = [ [ 5.0, -3.0, 1.0 ], [ 0, -4.0, 6.0 ], [ 0, 0, 2.0 ] ]

Example for a factorization of a tridiagonal matrix:

Matrix = [ [ -8.0, -8.0, 0.0, 0.0 ], [ -8.0, 6.0, -4.0, 0.0 ], [ 0.0, 7.0, -2.0, 7.0 ], [ 0.0, 0.0, 5.0, -3.0 ] ]

→ Matrix1 = [ [ 1, 0, 0, 0 ], [ 1.0, 1, 0, 0 ], [ 0.0, 0.5, 0.0, 1 ], [ 0.0, 0.0, 1, 0 ] ]
Matrix2 = [ [ -8.0, -8.0, 0.0, 0.0 ], [ 0, 14.0, -4.0, 0.0 ], [ 0, 0, 5.0, -3.0 ], [ 0, 0, 0, 7.0 ] ]

For MatrixType = 'symmetric' the factorization is a UDU^T decomposition (Upper/Diagonal/Upper) with the form

Matrix = Matrix1 * Matrix2 * Matrix1^T
```

Possible Predecessors

create_matrix

Possible Successors

get_full_matrix, get_value_matrix

See also

copy_matrix

Foundation
where the output Matrix\text{1} is an upper triangular matrix with interchanged columns. The output matrix Matrix\text{2} is a symmetric block diagonal matrix with 1 \times 1 and 2 \times 2 diagonal blocks.

Example for a factorization of a symmetric matrix:

\[
\begin{bmatrix}
3.0 & -2.0 & 7.0 & -1.0 \\
-2.0 & 4.0 & 8.0 & 1.0 \\
7.0 & -0.0 & 1.0 & 0.0 \\
-1.0 & 0.0 & 1.0 & 0.0
\end{bmatrix}
\]

\[\rightarrow \]

\[
\begin{bmatrix}
0 & 0 & 1 & 0.0 \\
0 & 1 & 0.0 & 2.0 \\
1 & -1.0 & -1.0 & -10.0 \\
0 & 0 & 0 & 1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
27.0 & 0 & 0 & 0 \\
0 & -2.0 & 0 & 0 \\
0 & 0 & 3.0 & -1.0 \\
0 & 0 & -1.0 & 0.0
\end{bmatrix}
\]

For MatrixType = ‘positive_definite’ a Cholesky factorization is computed with the form

\[
Matrix = Matrix1 \cdot Matrix2.
\]

where the output Matrix\text{1} is a lower triangular matrix and the output matrix Matrix\text{2} is an upper triangular matrix. Furthermore, the Matrix\text{2} is the transpose of the matrix Matrix\text{1}.

Example for a factorization of a positive definite matrix:

\[
\begin{bmatrix}
9.0 & 12.0 & -6.0 \\
12.0 & 17.0 & -7.0 \\
-6.0 & -7.0 & 14.0
\end{bmatrix}
\]

\[\rightarrow \]

\[
\begin{bmatrix}
3.0 & 0 & 0 \\
4.0 & 1.0 & 0 \\
-2.0 & 1.0 & 3.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
3.0 & 4.0 & -2.0 \\
0 & 1.0 & 1.0 \\
0 & 0 & 3.0
\end{bmatrix}
\]

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.

\begin{itemize}
  \item \textbf{Attention}
  \end{itemize}

For MatrixType = ‘symmetric’ or ‘positive_definite’, the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixType = ‘tridiagonal’, only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

\begin{itemize}
  \item \textbf{Parameters}
  \end{itemize}

- \textbf{MatrixID} (input_control) \hspace{2cm} \text{matrix} \mapsto handle
  
  \hspace{1cm} Matrix handle of the input matrix.

- \textbf{MatrixType} (input_control) \hspace{2cm} \text{string} \mapsto string
  
  \hspace{1cm} Type of the input matrix.
  
  \hspace{1cm} \textbf{Default value:} ‘general’
  
  \hspace{1cm} \textbf{List of values:} MatrixType ∈ \{‘general’, ‘symmetric’, ‘positive_definite’, ‘tridiagonal’\}

- \textbf{Matrix1ID} (output_control) \hspace{2cm} \text{matrix} \mapsto handle
  
  \hspace{1cm} Matrix handle with the output matrix 1.

- \textbf{Matrix2ID} (output_control) \hspace{2cm} \text{matrix} \mapsto handle
  
  \hspace{1cm} Matrix handle with the output matrix 2.

\begin{itemize}
  \item \textbf{Result}
  \end{itemize}

If the parameters are valid, the operator decompose_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

\begin{itemize}
  \item \textbf{Parallelization}
  \end{itemize}

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

References

Module

orthogonal_decompose_matrix ( : : MatrixID, DecompositionType,
OutputMatricesType, ComputeOrthogonal : MatrixOrthogonalID,
MatrixTriangularID )

Perform an orthogonal decomposition of a matrix.

The operator orthogonal_decompose_matrix decomposes the Matrix defined by the matrix handle MatrixID. The results are stored in the two generated matrices MatrixOrthogonal and MatrixTriangular. The operator returns the matrix handles MatrixOrthogonalID and MatrixTriangularID of these two matrices. Access to the elements of the matrices is possible e.g. with the operator get_full_matrix.

For OutputMatricesType = 'full' all results of the decomposition are stored in the matrices MatrixOrthogonal and MatrixTriangular. For OutputMatricesType = 'reduced' only a part of result elements of the matrices MatrixOrthogonal and MatrixTriangular are stored. Therefore the sizes of these matrices are smaller than for OutputMatricesType = 'full'.

For the parameter ComputeOrthogonal = 'true' both output matrices are computed. For the ComputeOrthogonal = 'false' only the matrix MatrixTriangular is computed. Thus, the runtime of the operation takes fewer time.

The type of the Matrix can be selected via the parameter DecompositionType. For DecompositionType = 'qr' a QR decomposition (Quadratic/Right) or for DecompositionType = 'ql' a QL decomposition (Quadratic/Left) is computed. The decomposition is written as

Matrix = MatrixOrthogonal · MatrixTriangular.

Example for DecompositionType = 'qr' and OutputMatricesType = 'full':

Matrix =
[ 6.0 -3.0 4.0 ]
[ -3.0 12.0 5.0 ]
[ 3.0 4.0 7.0 ]
[ 7.0 5.0 3.0 ]

→ MatrixOrthogonal =
[ -0.5303 0.2613 -0.4277 -0.5566 -0.3972 ]
[ -0.4419 -0.2920 -0.6383 0.1727 -0.5312 ]
[ 0.2652 -0.8443 -0.2059 -0.3961 -0.1326 ]
[ -0.2652 -0.2432 -0.6008 0.7000 -0.1400 ]
[ -0.6187 -0.2729 0.0799 -0.1160 0.7231 ]
Example for `DecompositionType` = 'qr' and `OutputMatricesType` = 'reduced':

\[
\begin{bmatrix}
6.0 & -3.0 & 4.0 \\
5.0 & 5.0 & -2.0 \\
-3.0 & 12.0 & 5.0 \\
3.0 & 4.0 & 7.0 \\
7.0 & 5.0 & 3.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
-0.5303 & 0.2613 & -0.4277 \\

0 & 0 & -10.1489
\end{bmatrix}
\]

\text{MatrixTriangular} =
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{bmatrix}

Example for DecompositionType = 'lq' and OutputMatricesType = 'full':

\[
\begin{bmatrix}
6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\
-3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\
4.0 & -2.0 & 5.0 & 7.0 & 3.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
-0.5303 & -0.4419 & 0.2652 & -0.2652 & -0.6187 \\
0.2613 & -0.2920 & -0.8443 & -0.2432 & -0.2729 \\
-0.4277 & 0.6383 & -0.2059 & -0.6008 & 0.0799 \\
-0.5566 & 0.1727 & -0.3961 & 0.7000 & -0.1160 \\
-0.3972 & -0.5312 & -0.1326 & -0.1400 & 0.7231
\end{bmatrix}
\]

\text{MatrixOrthogonal} =
\begin{bmatrix}
-11.3137 & 0 & 0 & 0 & 0 \\
-1.5910 & -14.7129 & 0 & 0 & 0 \\
-3.6239 & -5.1135 & -7.9824 & 0 & 0
\end{bmatrix}
\]

\text{MatrixTriangular} =
\begin{bmatrix}
-0.5303 & -0.4419 & 0.2652 & -0.2652 & -0.6187 \\
0.2613 & -0.2920 & -0.8443 & -0.2432 & -0.2729 \\
-0.4277 & 0.6383 & -0.2059 & -0.6008 & 0.0799 \\
-0.5566 & 0.1727 & -0.3961 & 0.7000 & -0.1160 \\
-0.3972 & -0.5312 & -0.1326 & -0.1400 & 0.7231
\end{bmatrix}

Example for DecompositionType = 'lq' and OutputMatricesType = 'reduced':

\[
\begin{bmatrix}
6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\
-3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\
4.0 & -2.0 & 5.0 & 7.0 & 3.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
-0.5303 & -0.4419 & 0.2652 & -0.2652 & -0.6187 \\
0.2613 & -0.2920 & -0.8443 & -0.2432 & -0.2729 \\
-0.4277 & 0.6383 & -0.2059 & -0.6008 & 0.0799
\end{bmatrix}
\]
MatrixTriangular =  
\[ 
\begin{bmatrix}
-11.317 & 0 & 0 \\
-1.5910 & -14.7129 & 0 \\
-3.6239 & -5.1135 & -7.9824 \\
\end{bmatrix}
\]

It should be noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

**Parameters**

- **MatrixID** (input_control)  
  Matrix handle of the input matrix.
- **DecompositionType** (input_control)  
  Method of decomposition.
  - Default value: 'qr'
  - List of values: DecompositionType ∈ {'qr', 'rq', 'ql', 'lq'}
- **OutputMatricesType** (input_control)  
  Type of output matrices.
  - Default value: 'full'
  - List of values: OutputMatricesType ∈ {'full', 'reduced'}
- **ComputeOrthogonal** (input_control)  
  Computation of the orthogonal matrix.
  - Default value: 'true'
  - List of values: ComputeOrthogonal ∈ {'true', 'false'}
- **MatrixOrthogonalID** (output_control)  
  Matrix handle with the orthogonal part of the decomposed input matrix.
- **MatrixTriangularID** (output_control)  
  Matrix handle with the triangular part of the decomposed input matrix.

**Result**

If the parameters are valid, the operator `orthogonal_decompose_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `create_matrix`

**Possible Successors**

- `get_full_matrix, get_value_matrix`
- `decompose_matrix, solve_matrix`

**References**

**Module**

- `svd_matrix`  
  Compute the singular value decomposition of a matrix.
The operator `svd_matrix` computes a full or reduced singular value decomposition (SVD) of the `Matrix` defined by the matrix handle `MatrixID`. The operator returns the matrix handle `MatrixSID` of the matrix `MatrixS` with singular values in descending order. Optionally, the matrices `MatrixU` with the left and `MatrixV` with the right singular vectors are computed and the matrix handles `MatrixUID` and `MatrixVID` are returned.

Access to the elements of the matrices is possible e.g. with the operator `get_full_matrix`. The SVD is written

\[ \text{Matrix} = \text{MatrixU} \cdot \text{MatrixS} \cdot \text{MatrixV}^T. \]

For `SVDType = 'full'`, a full SVD is computed.

Example:

\[
\begin{bmatrix}
6.0 & -5.0 \\
10.0 & 4.0 \\
-3.0 & 5.0
\end{bmatrix} \quad \text{SVDType} = 'full' \quad \text{ComputeSingularVectors} = 'both'
\]

\[
\rightarrow \quad \text{MatrixU} = \begin{bmatrix}
-0.5228 & 0.5691 & 0.6346 \\
-0.8070 & -0.5702 & -0.1535 \\
0.2745 & -0.5924 & 0.7574
\end{bmatrix} \quad \text{MatrixS} = \begin{bmatrix}
12.0547 & 0 \\
0 & 8.1046
\end{bmatrix}
\]

\[
\text{MatrixV} = \begin{bmatrix}
-0.9980 & -0.0629 \\
0.0629 & -0.9980
\end{bmatrix}
\]

For `SVDType = 'reduced'`, a reduced SVD is computed.

Example:

\[
\begin{bmatrix}
6.0 & -5.0 \\
10.0 & 4.0 \\
-3.0 & 5.0
\end{bmatrix} \quad \text{SVDType} = 'reduced' \quad \text{ComputeSingularVectors} = 'both'
\]

\[
\rightarrow \quad \text{MatrixU} = \begin{bmatrix}
-0.5228 & 0.5691 \\
-0.8070 & -0.5702 \\
0.2745 & -0.5924
\end{bmatrix} \quad \text{MatrixS} = \begin{bmatrix}
12.0547 & 0 \\
0 & 8.1046
\end{bmatrix}
\]

\[
\text{MatrixV} = \begin{bmatrix}
-0.9980 & -0.0629 \\
0.0629 & -0.9980
\end{bmatrix}
\]

For `ComputeSingularVectors = 'left'`, the matrix `MatrixU` with the left singular vectors is computed. For `ComputeSingularVectors = 'right'`, the matrix `MatrixV` with the right singular vectors is computed. For `ComputeSingularVectors = 'both'`, the matrices `MatrixU` and `MatrixV` with the left and right singular vectors are computed.

For `ComputeSingularVectors = 'none'`, no matrices with the singular vectors are computed. The matrix `MatrixS` is a matrix with \( n \) rows and one column, where the number \( n = \min(\text{number of rows of the input Matrix}, \text{number of columns of the input Matrix}) \).

Example:

\[
\begin{bmatrix}
6.0 & -5.0 \\
10.0 & 4.0 \\
-3.0 & 5.0
\end{bmatrix} \quad \text{SVDType} = 'reduced' \quad \text{ComputeSingularVectors} = 'none'
\]

\[
\rightarrow \quad \text{MatrixS} = \begin{bmatrix}
12.0547 \\
8.1046
\end{bmatrix}
\]

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.
### Parameters

- **MatrixID** (input_control) ... matrix handle of the input matrix.
- **SVDType** (input_control) ... string Type of computation.
  - Default value: ‘full’
  - List of values: \text{SVDType} \in \{ ‘full’, ‘reduced’ \}
- **ComputeSingularVectors** (input_control) ... string Computation of singular values.
  - Default value: ‘both’
  - List of values: \text{ComputeSingularVectors} \in \{ ‘none’, ‘left’, ‘right’, ‘both’ \}
- **MatrixUID** (output_control) ... matrix handle with the left singular vectors.
- **MatrixSID** (output_control) ... matrix handle with singular values.
- **MatrixVID** (output_control) ... matrix handle with the right singular vectors.

### Result

If the parameters are valid, the operator \texttt{svd_matrix} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- create_matrix

### Possible Successors

- get_full_matrix, get_value_matrix

#### 19.5 Eigenvalues

**eigenvalues_general_matrix** ( : : MatrixID,
  ComputeEigenvectors : EigenvaluesRealID, EigenvaluesImagID,
  EigenvectorsRealID, EigenvectorsImagID )

Compute the eigenvalues and optionally the eigenvectors of a general matrix.

The operator \texttt{eigenvalues_general_matrix} computes all eigenvalues and, optionally, the left or right eigenvectors of a square, general matrix. The matrix is defined by the matrix handle \texttt{MatrixID}. The computed eigenvectors have the norm 1.

The operator generates the new matrices \texttt{EigenvaluesReal} and \texttt{EigenvaluesImag} with the real and the imaginary parts of the computed eigenvalues. Each matrix has one column and \( n \) rows, where \( n \) is the number of rows of the input matrix. In contrast to the operator \texttt{eigenvalues_symmetric_matrix}, the order of the eigenvalues is not defined. The operator returns the matrix handles \texttt{EigenvaluesRealID} and \texttt{EigenvaluesImagID}. If desired, the real and imaginary parts of the computed eigenvectors are stored in the
new matrices \texttt{EigenvectorsReal} and \texttt{EigenvectorsImag}. For this, the operator returns valid matrix handles \texttt{EigenvectorsRealID} and \texttt{EigenvectorsImagID}. Access to the elements of the matrix is possible e.g. with the operator \texttt{get_full_matrix}.

The computation type of eigenvectors can be selected via the parameter \texttt{ComputeEigenvectors}. If \texttt{ComputeEigenvectors = 'none'}, no eigenvectors are computed. If 'left' is selected, the left eigenvalues are computed. If 'right' is selected, the right eigenvalues are computed.

Example:

\[
\text{Matrix} = \begin{bmatrix}
6.0 & 4.0 & -8.0 \\
5.0 & 7.0 & 3.0 \\
4.0 & -1.0 & 4.0
\end{bmatrix} \quad \text{ComputeEigenvectors = 'right'}
\]

\[
\rightarrow \quad \text{EigenvaluesReal} = \begin{bmatrix}
3.3110 \\
3.3110 \\
10.3781
\end{bmatrix} \quad \text{EigenvaluesImag} = \begin{bmatrix}
-5.4143 \\
-5.4143 \\
0.0
\end{bmatrix}
\]

\[
\text{EigenvectorsReal} = \begin{bmatrix}
0.6353 & 0.6353 & 0.4813 \\
-0.4764 & -0.4764 & 0.8605 \\
-0.0246 & -0.0246 & 0.1669
\end{bmatrix}
\]

\[
\text{EigenvectorsImag} = \begin{bmatrix}
0.0 & 0.0 & 0.0 \\
-0.2485 & 0.2485 & 0.0 \\
-0.5542 & 0.5542 & 0.0
\end{bmatrix}
\]

\begin{itemize}
  \item Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  \item Multithreading scope: global (may be called from any thread).
  \item Processed without parallelization.
\end{itemize}
References

Module
eigenvalues_symmetric_matrix ( : : MatrixID,
ComputeEigenvectors : EigenvaluesID, EigenvectorsID )

Compute the eigenvalues and optionally eigenvectors of a symmetric matrix.

The operator eigenvalues_symmetric_matrix computes all eigenvalues and, optionally, eigenvectors of the symmetric Matrix. The matrix is defined by the matrix handle MatrixID. On output, a new matrix Eigenvalues with the eigenvalues in ascending order and, optionally, a new matrix Eigenvectors with the eigenvectors is created. The operator returns the matrix handles EigenvaluesID and EigenvectorsID of the matrices Eigenvalues and Eigenvectors. Access to the elements of the matrices is possible e.g. with the operator get_full_matrix.

The computation of eigenvectors can be selected via ComputeEigenvectors = 'true' or ComputeEigenvectors = 'false'.

Example:

Matrix = [ 6.0 5.0 3.0 ]
[ 5.0 7.0 3.0 ]
[ 3.0 3.0 4.0 ]

ComputeEigenvectors = 'true'

→ Eigenvalues = [ 1.4195 ]
[ 2.1507 ]
[ 13.4298 ]

Eigenvectors = [ 0.7842 0.0626 0.6174 ]
[ −0.5667 0.4776 0.6714 ]
[ −0.2529 −0.8763 0.4100 ]

Attention

The upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

Parameters

▷ MatrixID (input_control) ................................................................. matrix ~ handle Matrix handle of the input matrix.
▷ ComputeEigenvectors (input_control) ........................................ string ~ string Computation of the eigenvectors.
  Default value: 'false'
  List of values: ComputeEigenvectors ∈ { 'true', 'false' }
▷ EigenvaluesID (output_control) .................................................. matrix ~ handle Matrix handle with the eigenvalues.
▷ EigenvectorsID (output_control) ................................................. matrix ~ handle Matrix handle with the eigenvectors.

Result

If the parameters are valid, the operator eigenvalues_symmetric_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

generalized_eigenvalues_general_matrix ( : : MatrixAID, MatrixBID, ComputeEigenvectors : EigenvaluesRealID, EigenvaluesImagID, EigenvectorsRealID, EigenvectorsImagID )

Compute the generalized eigenvalues and optionally the generalized eigenvectors of general matrices.

The operator generalized_eigenvalues_general_matrix computes all generalized eigenvalues and, optionally, the left or right generalized eigenvectors of the square, general matrices MatrixA and MatrixB. Both matrices must have identical dimensions. The matrices are defined by the matrix handles MatrixAID and MatrixBID. The computed eigenvectors have the norm 1.

The operator generates the new matrices EigenvaluesReal and EigenvaluesImag with the real and the imaginary parts of the computed eigenvalues. Each matrix has one column and n rows, where n is the number of rows or columns of the input matrices. In contrast to the operator generalized_eigenvalues_symmetric_matrix, the order of the generalized eigenvalues is not defined. The operator returns the matrix handles EigenvaluesRealID and EigenvaluesImagID. If desired, the real and imaginary parts of the respective eigenvectors are stored in the new matrices EigenvectorsReal and EigenvectorsImag. Here, the jth column of the matrices of eigenvectors contains the related eigenvector to the jth eigenvalue. For this, the operator returns additionally the matrix handles EigenvectorsRealID and EigenvectorsImagID. Access to the elements of the matrix is possible, e.g., with the operator get_full_matrix or get_sub_matrix.

The computation type of eigenvectors can be selected via the parameter ComputeEigenvectors. If ComputeEigenvectors = ‘none’, no eigenvectors are computed and the operator is faster. For this, the matrix handles EigenvectorsRealID and EigenvectorsImagID are invalid. If ‘right’ is selected, the right generalized eigenvalues are computed. The formula for the calculation of the result is

\[ \text{MatrixA} \cdot x_j = \lambda_j \cdot \text{MatrixB} \cdot x_j, \]

with \( \lambda_j \) representing the jth (complex) eigenvalue and \( x_j \) represents the corresponding (complex) eigenvector.

If ‘left’ is selected, the left generalized eigenvalues are computed. The formula for the calculation of the result is

\[ x_j^H \cdot \text{MatrixA} \cdot x_j^H \cdot \lambda_j \cdot \text{MatrixB}, \]

with \( x_j^H \) represents the conjugate-transposed of \( x_j \).

Example:

\[
\begin{align*}
\text{MatrixA} &= \begin{bmatrix} 6.0 & 4.0 & -8.0 \\ 5.0 & 7.0 & 3.0 \\ 4.0 & -1.0 & 4.0 \end{bmatrix} & \text{MatrixB} &= \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ -5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}
\end{align*}
\]
**ComputeEigenvectors** = 'right'

\[
\begin{bmatrix}
0.5363 \\
0.5363 \\
-6.1616
\end{bmatrix}
\]

**EigenvaluesReal**

\[
\begin{bmatrix}
0.3500 & 0.3500 & 0.0410 \\
-0.9565 & -0.9565 & 0.3267 \\
-0.2757 & -0.2757 & -1.0000
\end{bmatrix}
\]

**EigenvaluesImag**

\[
\begin{bmatrix}
-0.4644 & 0.4644 & 0.0 \\
0.0435 & -0.0435 & 0.0 \\
-0.1869 & 0.1869 & 0.0
\end{bmatrix}
\]

**EigenvectorsReal**

\[
\begin{bmatrix}
0.3500 & 0.3500 & 0.0410 \\
-0.9565 & -0.9565 & 0.3267 \\
-0.2757 & -0.2757 & -1.0000
\end{bmatrix}
\]

**EigenvectorsImag**

\[
\begin{bmatrix}
-0.4644 & 0.4644 & 0.0 \\
0.0435 & -0.0435 & 0.0 \\
-0.1869 & 0.1869 & 0.0
\end{bmatrix}
\]

**Parameters**

- **MatrixAID** (input_control)
  
  Matrix handle of the input matrix A.

- **MatrixBID** (input_control)
  
  Matrix handle of the input matrix B.

- **ComputeEigenvectors** (input_control)
  
  Computation of the eigenvectors.

  Default value: 'none'

  List of values: ComputeEigenvectors ∈ {'none', 'left', 'right'}

- **EigenvaluesRealID** (output_control)
  
  Matrix handle with the real parts of the eigenvalues.

- **EigenvaluesImagID** (output_control)
  
  Matrix handle with the imaginary parts of the eigenvalues.

- **EigenvectorsRealID** (output_control)
  
  Matrix handle with the real parts of the eigenvectors.

- **EigenvectorsImagID** (output_control)
  
  Matrix handle with the imaginary parts of the eigenvectors.

**Result**

If the parameters are valid, the operator *generalized_eigenvalues_general_matrix* returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

References

The operator `generalized_eigenvalues_symmetric_matrix` computes all generalized eigenvalues and, optionally, generalized eigenvectors of the symmetric matrix \( \text{MatrixA} \) and the symmetric positive definite matrix \( \text{MatrixB} \). Both matrices must have identical dimensions. The matrices are defined by the matrix handles `MatrixAID` and `MatrixBID`. On output, a new matrix `Eigenvalues` with the generalized eigenvalues in ascending order and, optionally, a new matrix `Eigenvectors` with the generalized eigenvectors is created.

Each \( j \)th column of the matrix `Eigenvectors` contains the related eigenvector to the \( j \)th eigenvalue. The operator returns the matrix handles `EigenvaluesID` and `EigenvectorsID` of the matrices `Eigenvalues` and `Eigenvectors`. Access to the elements of the matrices is possible, e.g., with the operator `get_full_matrix` or `get_sub_matrix`.

The computation of generalized eigenvectors can be selected via `ComputeEigenvectors = 'true'`. The formula for the calculation of the result is

\[
\text{MatrixA} \cdot x_j = \lambda_j \cdot \text{MatrixB} \cdot x_j,
\]

with \( \lambda_j \) representing the \( j \)th eigenvalue and \( x_j \) represents the corresponding eigenvector.

If `ComputeEigenvectors = 'false'`, no generalized eigenvectors are computed. For this, the matrix handle `EigenvectorsID` is invalid.

Example:

\[
\begin{align*}
\text{MatrixA} &= \begin{bmatrix}
4.0 & -3.0 & 2.0 \\
-3.0 & 1.0 & 4.0 \\
2.0 & 4.0 & 8.0
\end{bmatrix} \\
\text{MatrixB} &= \begin{bmatrix}
6.0 & 5.0 & 3.0 \\
5.0 & 7.0 & 3.0 \\
3.0 & 3.0 & 4.0
\end{bmatrix} \\
\text{ComputeEigenvectors} &= 'true' \\
\Rightarrow \quad \text{Eigenvalues} &= \begin{bmatrix}
-0.4463 \\
1.8747 \\
4.5472
\end{bmatrix} \\
\text{Eigenvectors} &= \begin{bmatrix}
-0.1579 & 0.1851 & -0.6358 \\
-0.3377 & -0.2568 & 0.4311 \\
0.2382 & 0.5065 & 0.3185
\end{bmatrix}
\end{align*}
\]

Attention

The upper triangular parts of the input matrices `MatrixA` and `MatrixB` must contain the relevant information of the matrices. The strictly lower triangular parts of the matrices are not referenced. If the referenced parts of the input matrices `MatrixA` or `MatrixB` are not of the specified type, an exception is raised.

---

**Parameters**

- `MatrixAID` (input_control) ............................. matrix  \( \Rightarrow \) handle  
  Matrix handle of the symmetric input matrix A.
- `MatrixBID` (input_control) ............................. matrix  \( \Rightarrow \) handle  
  Matrix handle of the symmetric positive definite input matrix B.
- `ComputeEigenvectors` (input_control) ......................... string  \( \Rightarrow \) string  
  Computation of the eigenvectors.
  **Default value:** 'false'
  **List of values:** `ComputeEigenvectors \in \{ 'true', 'false' \}`
- `EigenvaluesID` (output_control) ............................. matrix  \( \Rightarrow \) handle  
  Matrix handle with the eigenvalues.
- `EigenvectorsID` (output_control) ............................. matrix  \( \Rightarrow \) handle  
  Matrix handle with the eigenvectors.

---

**Result**

If the parameters are valid, the operator `generalized_eigenvalues_symmetric_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

### `determinant_matrix ( : : MatrixID, MatrixType : Value )`

Compute the determinant of a matrix.

The operator `determinant_matrix` computes the determinant of the input Matrix given by the matrix handle `MatrixID`. The type of the input Matrix can be selected via the parameter `MatrixType`. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'tridiagonal' for tridiagonal, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices. The formula for the calculation of the result is:

\[
\text{Value} = \det \text{Matrix}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix} \rightarrow \text{Value} = -134.0
\]

---

### Attention

For `MatrixType = 'symmetric'`, 'positive_definite', or 'upper_triangular' the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixType = 'lower_triangular'` the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For `MatrixType = 'tridiagonal'`, only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

---

### Parameters

- `MatrixID` (input_control) ~ handle
  Matrix handle of the input matrix.
- `MatrixType` (input_control) ~ string
  The type of the input matrix.

**Default value**: 'general'

19.6. FEATURES

Value (output_control) ................................................................. real \rightsquigarrow real
Determinant of the input matrix.

If the parameters are valid, the operator determinant_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

get_size_matrix ( : : MatrixID : Rows, Columns )

Get the size of a matrix.
The operator get_size_matrix returns the number of rows Rows and columns Columns of the input Matrix. The input Matrix is defined by the matrix handle MatrixID.

Parameters

MatrixID (input_control) ................................................................. matrix \rightsquigarrow handle
Matrix handle of the input matrix.

Rows (output_control) ................................................................. integer \rightsquigarrow integer
Number of rows of the matrix.

Columns (output_control) ................................................................. integer \rightsquigarrow integer
Number of columns of the matrix.

If the parameters are valid, the operator get_size_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors

clear_matrix

Module

max_matrix ( : : MatrixID, MaxType : MatrixMaxID )

Returns the elementwise maximum of a matrix.
The operator \texttt{max\_matrix} returns the maximum values of the elements of the \texttt{Matrix} defined by the matrix handle \texttt{MatrixID}. A new matrix \texttt{MatrixMax} is generated with the result and the matrix handle \texttt{MatrixMaxID} of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator \texttt{get\_full\_matrix}.

The type of maximum determination of the matrix can be selected via the parameter \texttt{MaxType}:

- \texttt{'columns'}: The maximum is returned for each column of the \texttt{Matrix} separately. The resulting matrix \texttt{MatrixMax} has one row and the identical number of columns as the input matrix.
  
  Example:
  
  \[
  \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0
  \end{bmatrix}
  \]
  \texttt{MaxType} = \texttt{'columns'}
  
  \[
  \begin{bmatrix}
  8.0 & 4.0 & 7.0
  \end{bmatrix}
  \]

- \texttt{'rows'}: The maximum is returned for each row of the \texttt{Matrix} separately. The resulting matrix \texttt{MatrixMax} has the identical number of rows as the input matrix and one column.
  
  Example:
  
  \[
  \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0
  \end{bmatrix}
  \]
  \texttt{MaxType} = \texttt{'rows'}
  
  \[
  \begin{bmatrix}
  8.0 \\
  7.0
  \end{bmatrix}
  \]

- \texttt{'full'}: The maximum is returned using all elements of the \texttt{Matrix}. The resulting matrix \texttt{MatrixMax} has one row and one column.
  
  Example:
  
  \[
  \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0
  \end{bmatrix}
  \]
  \texttt{MaxType} = \texttt{'full'}
  
  \[
  \begin{bmatrix}
  8.0
  \end{bmatrix}
  \]

\begin{itemize}
  \item \texttt{MatrixID} (input\_control) \texttt{matrix} \rightarrow \texttt{handle} \\
  \text{Matrix handle of the input matrix.}
  \item \texttt{MaxType} (input\_control) \texttt{string} \rightarrow \texttt{string} \\
  \text{Type of maximum determination.}
  \text{Default value:} \texttt{'columns'}
  \text{List of values:} \texttt{MaxType} \in \{\texttt{'columns'}, \texttt{'rows'}, \texttt{'full'}\}
  \item \texttt{MatrixMaxID} (output\_control) \texttt{matrix} \rightarrow \texttt{handle} \\
  \text{Matrix handle with the maximum values of the input matrix.}
\end{itemize}

If the parameters are valid, the operator \texttt{max\_matrix} returns the value 2 (\texttt{H\_MSG\_TRUE}). If necessary, an exception is raised.

\begin{itemize}
  \item Multithreading type: reentrant (runs in parallel with non-exclusive operators).

\end{itemize}
The operator `mean_matrix` returns the mean values of the elements of the matrix defined by the matrix handle `MatrixID`. A new matrix `MatrixMean` is generated with the result and the matrix handle `MatrixMeanID` of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

The type of mean determination of the matrix can be selected via the parameter `MeanType`:

'columns': The mean is returned for each column of the matrix separately. The resulting matrix `MatrixMean` has one row and the identical number of columns as the input matrix.

Example:

\[
\text{Matrix} = \begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}, \quad \text{MeanType} = 'columns' \\
\Rightarrow \quad \text{MatrixMean} = \begin{bmatrix}
1.0 & 3.0 & 2.0
\end{bmatrix}
\]

'rows': The mean is returned for each row of the matrix separately. The resulting matrix `MatrixMean` has the identical number of rows as the input matrix and one column.

Example:

\[
\text{Matrix} = \begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}, \quad \text{MeanType} = 'rows' \\
\Rightarrow \quad \text{MatrixMean} = \begin{bmatrix}
3.0 \\
1.0
\end{bmatrix}
\]

'full': The mean is returned using all elements of the matrix. The resulting matrix `MatrixMean` has one row and one column.

Example:

\[
\text{Matrix} = \begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}, \quad \text{MeanType} = 'full' \\
\Rightarrow \quad \text{MatrixMean} = \begin{bmatrix}
2.0
\end{bmatrix}
\]
Returns the elementwise minimum of a matrix.

The operator min_matrix returns the minimum values of the elements of the Matrix defined by the matrix handle MatrixID. A new matrix MatrixMin is generated with the result and the matrix handle MatrixMinID of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

The type of minimum determination of the matrix can be selected via the parameter MinType:

'columns': The minimum is returned for each column of the Matrix separately. The resulting matrix MatrixMin has one row and the identical number of columns as the input matrix.

Example:

\[
\text{Matrix} = \begin{bmatrix} 8.0 & 4.0 & -3.0 \\ -6.0 & 2.0 & 7.0 \end{bmatrix} \quad \text{MinType} = \text{'columns'}
\]

\[ \rightarrow \quad \text{MatrixMin} = \begin{bmatrix} -6.0 \\ 2.0 \\ -3.0 \end{bmatrix} \]

'rows': The minimum is returned for each row of the Matrix separately. The resulting matrix MatrixMin has the identical number of rows as the input matrix and one column.

Example:

\[
\text{Matrix} = \begin{bmatrix} 8.0 & 4.0 & -3.0 \\ -6.0 & 2.0 & 7.0 \end{bmatrix} \quad \text{MinType} = \text{'rows'}
\]

\[ \rightarrow \quad \text{MatrixMin} = \begin{bmatrix} -3.0 \\ -6.0 \end{bmatrix} \]

'full': The minimum is returned using all elements of the Matrix. The resulting matrix MatrixMin has one row and one column.

Example:

\[
\text{Matrix} = \begin{bmatrix} 8.0 & 4.0 & -3.0 \\ -6.0 & 2.0 & 7.0 \end{bmatrix} \quad \text{MinType} = \text{'full'}
\]

\[ \rightarrow \quad \text{MatrixMin} = \begin{bmatrix} -6.0 \end{bmatrix} \]

### Parameters

- **MatrixID** (input_control) ................................. matrix  \( \rightarrow \) handle
  Matrix handle of the input matrix.

- **MinType** (input_control) ................................. string  \( \rightarrow \) string
  Type of minimum determination.

  **Default value:** 'columns'

  **List of values:** MinType \( \in \{ \text{'columns', 'rows', 'full'} \} \)

- **MatrixMinID** (output_control)............................ matrix  \( \rightarrow \) handle
  Matrix handle with the minimum values of the input matrix.
If the parameters are valid, the operator min_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Module

**norm_matrix** ( : : MatrixID, NormType : Value )

**Norm of a matrix.**

The operator norm_matrix computes the norm of the elements of the Matrix defined by the matrix handle MatrixID. The return value is a floating point number.

The type of norming of the matrix can be selected via the parameter NormType:

'-frobenius-norm': The Frobenius norm is computed. The formula for the calculation of the result is:

\[ Value = \sqrt{\sum_{i=0}^{m-1} \sum_{j=0}^{n-1} Matrix_{ij}^2} \]

with \( m = \) number of rows and \( n = \) number of columns of the Matrix.

Example:

Matrix = \[
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\] \( \rightarrow \) Value = 10.0

'-infinity-norm': The infinity norm is computed. The result is the largest value of the sum of the absolute values of the elements of the rows. The formula for the calculation is:

\[ Value = \max_{i=0,m-1} \left( \sum_{j=0}^{n-1} |Matrix_{ij}| \right) \]

with \( m = \) number of rows and \( n = \) number of columns of the Matrix.

Example:

Matrix = \[
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\] \( \rightarrow \) Value = 11.0

'-1-norm': The 1-norm is computed. The result is the largest value of the sum of the absolute values of the elements of the columns. The formula for the calculation is:
\[
\text{Value} = \max_{j=0,...,n-1} \sum_{i=0}^{m-1} |\text{Matrix}_{ij}|
\]

with \(m\) = number of rows and \(n\) = number of columns of the Matrix.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\end{bmatrix} \rightarrow \text{Value} = 14.0
\]

'2-norm': The 2-norm is computed. The result is the largest singular value of the Matrix. The formula for the calculation of the result is:

\[
\text{Value} = \max (\text{singular values (Matrix)})
\]

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\end{bmatrix} \rightarrow \text{Value} = 9.7006
\]
The operator `sum_matrix` returns the sum of the elements of the `Matrix` defined by the matrix handle `MatrixID`. A new matrix `MatrixSum` is generated with the result and the matrix handle `MatrixSumID` of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

The type of sum determination of the matrix can be selected via the parameter `SumType`:

'columns': The sum is returned for each column of the `Matrix` separately. The resulting matrix `MatrixSum` has one row and the identical number of columns as the input matrix.

Example:

\[
\begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
2.0 & 6.0 & 4.0
\end{bmatrix}
\]

'rows': The sum is returned for each row of the `Matrix` separately. The resulting matrix `MatrixSum` has the identical number of rows as the input matrix and one column.

Example:

\[
\begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
9.0 \\
3.0
\end{bmatrix}
\]

'full': The sum is returned using all elements of the `Matrix`. The resulting matrix `MatrixSum` has one row and one column.

Example:

\[
\begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
12.0
\end{bmatrix}
\]

--- Parameters ---

- **MatrixID** (input_control) ................................. matrix \(\mapsto\) handle Matrix handle of the input matrix.
- **SumType** (input_control) ................................. string \(\mapsto\) string Type of summation.
  Default value: 'columns'
  List of values: SumType \(\in\) {'columns', 'rows', 'full'}
- **MatrixSumID** (output_control) ......................... matrix \(\mapsto\) handle Matrix handle with the sum of the input matrix.

--- Result ---

If the parameters are valid, the operator `sum_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

19.7 File

deserialize_matrix ( : : SerializedItemHandle : MatrixID )

Deserialize a serialized matrix.

deserialize_matrix deserializes a matrix, that was serialized by serialize_matrix (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized matrix is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created matrix with the handle MatrixID. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

Parameters

- SerializedItemHandle (input_control) serialized_item handle of the serialized item.
- MatrixID (output_control) Matrix handle.

Result

If the parameters are valid, the operator deserialize_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_matrix

Possible Successors

get_full_matrix

Module

read_matrix ( : : FileName : MatrixID )

Read a matrix from a file.

The operator read_matrix reads a matrix, which has been written to the file with write_matrix, from the file FileName. The default HALCON file extension for the matrix is 'mtx'. The format of the file can be binary or ascii. Each row of the file contains one row of a matrix with a number of columns. The columns are separated with white spaces or tabs. Each row must have the same number of columns. Empty lines are ignored.

The reading results are stored in the matrix Matrix. The operator returns the matrix handle MatrixID of this matrix. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

Parameters

- FileName (input_control) filename read string File name.
- MatrixID (output_control) matrix handle.

Result

If the file name is valid, the operator read_matrix returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

get_full_matrix

Module

Foundation

**serialize_matrix** ( : : MatrixID : SerializedItemHandle )

**Serializes a matrix.**

 serialize_matrix serializes the data of a matrix (see **fwrite_serialized_item** for an introduction of the basic principle of serialization). The same data that is written in a file by **write_matrix** is converted to a serialized item. The matrix is defined by the handle **MatrixID**. The serialized matrix is returned by the handle **SerializedItemHandle** and can be deserialized by **deserialize_matrix**.

**Parameters**

▷ **MatrixID** (input_control) .......................................................... matrix  ⇐ handle
  Matrix handle.

▷ **SerializedItemHandle** (output_control) .............................. serialized_item  ⇐ handle
  Handle of the serialized item.

**Result**

If the parameters are valid, the operator **serialize_matrix** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

create_matrix

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_matrix

Module

Foundation

**write_matrix** ( : : MatrixID, FileFormat, FileName : )

**Write a matrix to a file.**

The operator **write_matrix** writes a matrix to the file **FileName**. The matrix can be read with **read_matrix**. The default HALCON file extension for the matrix is ’mtx’. The format of the file can be selected via the parameter **FileFormat**. The following values are supported: ’binary’ for a binary file format, and ’ascii’ for a ascii text format. In the text format each row of the file contains one row of the matrix. The columns are separated with white spaces. The advantage of using the binary file format instead of the ascii text format is a smaller size of the output file.
 Parameters

▷ **MatrixID** (input_control) .......................... \textit{matrix} \xrightarrow{} \textit{handle}
   Matrix handle of the input matrix.
▷ **FileFormat** (input_control) .......................... \textit{string} \xrightarrow{} \textit{string}
   Format of the file.
   \textbf{Default value:} ‘binary’
   \textbf{List of values:} \textit{FileFormat} \in \{‘binary’, ‘ascii’\}
▷ **FileName** (input_control) .......................... \textit{filename.write} \xrightarrow{} \textit{string}
   File name.
   \textbf{File extension:} .\textit{mtx}

 Result

If the file name is valid (write permission), the operator \texttt{write\_matrix} returns the value 2 (H\_MSG\_TRUE). If necessary an exception is raised.

 Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Chapter 20

Morphology

20.1 Gray Values

This chapter describes operators of gray value morphology.

Concept of Gray Value Morphology

Gray value morphology provides a set of operators that allow the non-linear manipulation of gray values in an image, depending on their pixel neighborhood. For instance, morphological gray value operators can be used to smooth or emphasize structural features in images. Unlike the binary operations in Morphology / Region, morphological gray value operators deal with input images that contain pixels with a range of more than one bit. Therefore gray value morphology can be seen as a generalization of region morphology. In the following paragraphs, we will take a closer look at the morphological gray value operators.

Dilation and Erosion of a Grayscale Image

To perform a dilation or erosion, each pixel of the image is assigned a gray value depending on its neighborhood. Area and shape of the neighborhood affecting each pixel are defined by the chosen structuring element with the current pixel being the reference point. Implementing a dilation, every pixel of the input image is assigned the maximum gray value of its neighborhood, respectively the minimum gray value for an erosion. Accordingly, bright areas of the input image are enlarged by gray value dilation, whereas gray value erosion emphasizes dark areas.

These operators can be used to dilate or erode an image:

<table>
<thead>
<tr>
<th>Morphological Operator</th>
<th>Structuring Element</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gray_dilation</code></td>
<td><code>gray_erosion</code></td>
</tr>
<tr>
<td><code>gray_dilation_rect</code></td>
<td><code>gray_erosion_rect</code></td>
</tr>
<tr>
<td><code>gray_dilation_shape</code></td>
<td><code>gray_erosion_shape</code></td>
</tr>
</tbody>
</table>
Morphological grayscale operations are often part of the preprocessing of images before information can be extracted properly. The following example displays a case where a gray value erosion is necessary to read data code symbols. In order to fit a data model used for decoding, the gaps between the code elements in the image need to be reduced by enlarging local minima in a square shape. Therefore a gray value erosion is performed, using an adequately sized rectangle as the structuring element. The rectangle size depends on the data model created with `create_data_code_2d_model`, where the acceptable module gap size is determined.

Opening and Closing

Gray value opening and gray value closing operators each are a combination of the operators explained above. Closing is a dilation followed by an erosion, while for an opening an erosion precedes a dilation operation. As seen in the example images, `gray_closing` reduces or even removes parts of the image that are darker than their neighborhood whereas `gray_opening` reduces lighter areas. Furthermore, using a suited structuring element you can preserve shapes while removing unwanted image artifacts.

Further Operators

To take a closer look at areas that are affected by gray value opening or closing, you can perform a `gray_tophat` or `gray_bothat` transformation. The resulting image displays the difference between the original image and the opening respectively closing of an image. You can also use these operators to detect structures that match the shape of the structuring element.

The `gray_range_rect` operator gives you the opportunity to detect fine structures on homogeneous surfaces by visualizing the extent of local variations in pixel values.
By applying the `gray_range_rect` operator you can perform a mitigated form of a gray value opening or closing operation. You can control the transformation by adjusting the parameter `ModePercent`.

Dual rank operations: (1) `ModePercent = 0` (equals opening), (2) `ModePercent = 25`, (3) `ModePercent = 50` (equals median), (4) `ModePercent = 75`, (5) `ModePercent = 100` (equals closing).

Glossary
In the following list, the most important terms that are used in the context of Morphology are described.

**non-linear operator**  Operator which does not necessarily preserve structures of the input image

**structuring element**  Region which is used to scan the input image.

```
dual_rank ( Image : ImageRank : MaskType, Radius, ModePercent, Margin : )
```

Opening, Median and Closing with circle or rectangle mask.

The operator `dual_rank` carries out a non-linear transformation of the gray values of all input images (`Image`). Circles or squares can be used as structuring elements. The operator `dual_rank` effects two consecutive calls of `rank_image`. At the first call the range gray value is calculated with the indicated range (`ModePercent`). The result of this calculation is the input of a further call of `rank_image`, this time using the range value 100–`ModePercent`.

When filtering different parameters for border treatment (`Margin`) can be chosen:

- **gray value**  Pixels outside of the image edges are assumed to be constant (with the indicated gray value).
- **'continued'**  Continuation of edge pixels.
- **'cyclic'**  Cyclic continuation of image edges.
- **'mirrored'**  Reflection of pixels at the image edges.
A range filtering is calculated according to the following scheme: The indicated mask is put over the image to be filtered in such a way that the center of the mask touches all pixels once. For each of these pixels all neighboring pixels covered by the mask are sorted in an ascending sequence corresponding to their gray values. Each sorted sequence of gray values contains the same number of gray values like the mask has image points. The n-th highest element, (\(= \text{ModePercent}\), rank values between 0...100 in percent) is selected and set as result gray value in the corresponding result image.

If \(\text{ModePercent} = 0\), then the operator equals to the gray value opening (\(\text{gray_opening}\)). If \(\text{ModePercent} = 50\), the operator results in the median filter, which is applied twice (\(\text{median_image}\)). The \(\text{ModePercent} = 100\) in \(\text{dual_rank}\) means that it calculates the gray value closing (\(\text{gray_closing}\)). Choosing parameter values inside this range results in a smooth transformation of these operators.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

**Parameters**

\[\text{Image} \text{ (input_object)} \rightarrow \text{object} : \text{byte} / \text{int2} / \text{uint2} / \text{int4} / \text{real} \]

Image to be filtered.

\[\text{ImageRank} \text{ (output_object)} \rightarrow \text{object} : \text{byte} / \text{int2} / \text{uint2} / \text{int4} / \text{real} \]

Filtered Image.

\[\text{MaskType} \text{ (input_control)} \rightarrow \text{string} \]

Shape of the mask.

Default value: 'circle'

List of values: \(\text{MaskType} \in \{\text{'circle'}, \text{'square'}\}\)

\[\text{Radius} \text{ (input_control)} \rightarrow \text{integer} \]

Radius of the filter mask.

Default value: 1

Suggested values: \(\text{Radius} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 15, 19, 25, 31, 39, 47, 59\}\)

Typical range of values: \(1 \leq \text{Radius} \leq 101\)

Minimum increment: 1

Recommended increment: 2

\[\text{ModePercent} \text{ (input_control)} \rightarrow \text{integer} \]

Filter Mode: 0 corresponds to a gray value opening , 50 corresponds to a median and 100 to a gray values closing.

Default value: 10

Suggested values: \(\text{ModePercent} \in \{0, 2, 5, 10, 15, 20, 40, 50, 60, 80, 85, 90, 95, 98, 100\}\)

Typical range of values: \(0 \leq \text{ModePercent} \leq 100\)

Minimum increment: 1

Recommended increment: 2

\[\text{Margin} \text{ (input_control)} \rightarrow \text{string} \]

Border treatment.

Default value: 'mirrored'

Suggested values: \(\text{Margin} \in \{\text{'mirrored'}, \text{'cyclic'}, \text{'continued'}, 0, 30, 60, 90, 120, 150, 180, 210, 240, 255\}\)

Example

\[
\text{read_image} (\text{Image}, \text{'fabrik'})
\]

\[
\text{dual_rank} (\text{Image}, \text{ImageOpening}, \text{'circle'}, 10, 10, \text{'mirrored'})
\]

\[
\text{dev_display} (\text{ImageOpening})
\]

Complexity

For each pixel: \(O(\sqrt{F} \times 10)\) with \(F = \text{area of the structuring element}\).

Result

If the parameter values are correct the operator \(\text{dual_rank}\) returns the value 2 (\(\text{H_MSG_TRUE}\)). The behavior in case of empty input (no input images available) is set via the operator \(\text{set_system}('\text{no_object_result}', <\text{Result}>)\). If necessary an exception is raised.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on domain level.

References

Module

```
gen_disc_se ( : SE : Type, Width, Height, Smax : )
```

Generate ellipsoidal structuring elements for gray morphology.

gendisc_se generates an ellipsoidal structuring element (SE) for gray morphology of images. The parameter
Type determines the image type. It must match the image type of the image to be processed in subsequent operator
calls using this structuring element. The parameters Width and Height determine the length of the two major
axes of the ellipse. The value of Smax determines the maximum gray value of the structuring element. For the
generation of arbitrary structuring elements, see read_gray_se. The structuring element can be saved as image
with the help of the operator write_image. However, take care to use an image format that supports alpha
channels to save the shape of the structuring element such as ’tiff’, ’jp2’ or ’png’. These files can then be loaded
again with the operator read_image.

Parameters

- **SE** (output_object) 
  - Generated structuring element.
- **Type** (input_control) 
  - Pixel type.
  - **Default value**: ’byte’
  - **List of values**: Type ∈ [’byte’, ’uint2’, ’real’]
- **Width** (input_control) 
  - Width of the structuring element.
  - **Default value**: 5
  - **Suggested values**: Width ∈ [0, 1, 2, 3, 4, 5, 10, 15, 20]
  - **Typical range of values**: 0 ≤ Width ≤ 511 (lin)
  - **Minimum increment**: 1
  - **Recommended increment**: 1
- **Height** (input_control) 
  - Height of the structuring element.
  - **Default value**: 5
  - **Suggested values**: Height ∈ [0, 1, 2, 3, 4, 5, 10, 15, 20]
  - **Typical range of values**: 0 ≤ Height ≤ 511 (lin)
  - **Minimum increment**: 1
  - **Recommended increment**: 1
Maximum gray value of the structuring element.

**Default value:** 0

**Suggested values:** \( \text{Smax} \in \{0, 1, 2, 5, 10, 20, 30, 40\} \)

---

**Result**

\( \text{gen_disc_se} \) returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Successors

\( \text{gray_erosion, gray_dilation, gray_opening, gray_closing, gray_tophat, gray_bothat, write_image} \)

### Alternatives

\( \text{read_gray_se, read_image} \)

### See also

\( \text{paint_region, paint_gray, crop_part} \)

### Module

**Foundation**

---

**gray_bothat** ( `Image`, `SE` : **ImageBotHat** : : )

Perform a gray value bottom hat transformation on an image.

\( \text{gray_bothat} \) applies a gray value bottom hat transformation to the input image `Image` with the structuring element \( \text{SE} \). The image type of the structuring element `SE` must match the image type of the input image `Image`. The gray value bottom hat transformation of an image \( i \) with a structuring element \( s \) is defined as

\[
\text{bothat}(i, s) = (i \cdot s) - i,
\]

i.e., the difference of the closing of the image with \( s \) and the image (see `gray_closing`). For the generation of structuring elements, see `read_gray_se`.

The gray value erosion is particularly fast for flat structuring elements, i.e. structuring elements with a constant gray level within their domain.

### Parameters

- **Image** (input_object) ................. (multichannel-image-array) \( \sim \) object : byte / uint2 / real
  - Input image.
- **SE** (input_object) ...................... singlechannel-image \( \sim \) object : byte / uint2 / real
  - Structuring element.
- **ImageBotHat** (output_object) ........... (multichannel-image-array) \( \sim \) object : byte / uint2 / real
  - Bottom hat image.

### Result

\( \text{gray_bothat} \) returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on internal data level.

gray_tophat, top_hat, gray_erosion_rect, sub_image

Module

Foundation

```
gray_closing ( Image, SE : ImageClosing : : )
```

Perform a gray value closing on an image.

gray_closing applies a gray value closing to the input image `Image` with the structuring element `SE`. The image type of the structuring element `SE` must match the image type of the input image `Image`. The gray value closing of an image `i` with a structuring element `s` is defined as

\[ i * s = (i \oplus s) \ominus \bar{s} , \]

i.e., a dilation of the image with `s` followed by an erosion with the transposed structuring element (see `gray_dilation` and `gray_erosion`). For the generation of structuring elements, see `read_gray_se`.

The gray value closing is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

Parameters

- `Image` (input_object) ......................... (multichannel-)imaget-array \( \Rightarrow \) object : byte / uint2 / real
  Input image.
- `SE` (input_object) ............................. singlechannelimage \( \Rightarrow \) object : byte / uint2 / real
  Structuring element.
- `ImageClosing` (output_object) ............ (multichannel-)imaget-array \( \Rightarrow \) object : byte / uint2 / real
  Gray-closed image.

Result

`gray_closing` returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Possible Predecessors

read_gray_se, gen_disc_se, read_image

Alternatives

dual_rank, gray_closing_rect, gray_closing_shape

See also

closing, gray_dilation, gray_erosion

Module

Foundation
Perform a gray value closing with a rectangular mask.

`gray_closing_rect` applies a gray value closing to the input image `Image` with a rectangular mask of size `(MaskHeight, MaskWidth)`. The resulting image is returned in `ImageClosing`. If the parameters `MaskHeight` or `MaskWidth` are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

The gray value closing of an image `i` with a rectangular structuring element `s` is defined as

\[ i \circ s = (i \oplus s) \ominus s, \]

i.e., a dilation of the image with `s` followed by an erosion with `s` (see `gray_dilation_rect` and `gray_erosion_rect`).

---

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

---

### Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) $\sim$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  - Input image.

- **ImageClosing** (output_object) ...... (multichannel-)image(-array) $\sim$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  - Gray-closed image.

- **MaskHeight** (input_control) ......................... extent.y $\sim$ integer
  - Height of the filter mask.
  - Default value: 11
  - Suggested values: `MaskHeight` $\in \{3, 5, 7, 9, 11, 13, 15\}$
  - Typical range of values: $3 \leq \text{MaskHeight} \leq 511$
  - Minimum increment: 2
  - Recommended increment: 2
  - Restriction: `odd(MaskHeight)` && `MaskHeight < \text{height(Image)} \times 2`

- **MaskWidth** (input_control) ......................... extent.x $\sim$ integer
  - Width of the filter mask.
  - Default value: 11
  - Suggested values: `MaskWidth` $\in \{3, 5, 7, 9, 11, 13, 15\}$
  - Typical range of values: $3 \leq \text{MaskWidth} \leq 511$
  - Minimum increment: 2
  - Recommended increment: 2
  - Restriction: `odd(MaskWidth)` && `MaskWidth < \text{width(Image)} \times 2`

---

### Result

`gray_closing_rect` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

---

### Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

### Alternatives

- `gray_closing`

20.1. GRAY VALUES

See also closing_rectangle1, gray_dilation_rect, gray_erosion_rect

Module Foundation

gray_closeing_shape ( Image : ImageClosing : MaskHeight, MaskWidth, MaskShape : )

Perform a gray value closing with a selected mask.

gray_closeing_shape applies a gray value closing to the input image Image with the structuring element of shape MaskShape. The mask’s offset values are 0 and its horizontal and vertical size is defined by MaskHeight and MaskWidth. The resulting image is returned in ImageClosing.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageClosing is interpolated from the two intermediate images. Therefore, note that gray_closeing_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values ‘rhombus’ and ‘octagon’ for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value ‘octagon’ for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

The gray value closing of an image i with a structuring element s is defined as

\[ i \ast s = (i \oplus s) \ominus s , \]

i.e., a dilation of the image with s followed by an erosion with s (see gray_dilation_shape and gray_erosion_shape).

Attention

Note that gray_closeing_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_closeing_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) ............................................................... (multichannel-)image(-array) \( \sim object : \text{byte} / \text{uint2} \)
  Image for which the minimum gray values are to be calculated.

- **ImageClosing** (output_object) ....................................................... (multichannel-)image(-array) \( \sim object : \text{byte} / \text{uint2} \)
  Image containing the minimum gray values.

- **MaskHeight** (input_control) .............................................. extent.y \( \sim \text{real} / \text{integer} \)
  Height of the filter mask.
  Default value: 11
  Suggested values: \( \text{MaskHeight} \in \{3, 5, 7, 9, 11, 13, 15\} \)
  Typical range of values: \( 1.0 \leq \text{MaskHeight} \leq 511.0 \)

- **MaskWidth** (input_control) .............................................. extent.x \( \sim \text{real} / \text{integer} \)
  Width of the filter mask.
  Default value: 11
  Suggested values: \( \text{MaskWidth} \in \{3, 5, 7, 9, 11, 13, 15\} \)
  Typical range of values: \( 1.0 \leq \text{MaskWidth} \leq 511.0 \)

- **MaskShape** (input_control) .................................................. string \( \sim \text{string} \)
  Shape of the mask.
  Default value: ‘octagon’
  List of values: \( \text{MaskShape} \in \{ \text{‘rectangle’}, \text{‘rhombus’}, \text{‘octagon’} \} \)
Result

gray_closing_shape returns 2 (H_MSG_TRUE) if all parameters are correct.

Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

gray_closing

See also

gray_dilation_shape, gray_erosion_shape, closing

Module

Foundation

gray_dilation ( Image, SE : ImageDilation : : )

Perform a gray value dilation on an image.

gray_dilation applies a gray value dilation to the input image Image with the structuring element SE. The image type of the structuring element SE must match the image type of the input image Image. The gray value dilation of an image \( i \) with a structuring element \( s \) at the pixel position \( x \) is defined as:

\[
(i \oplus s)(x) = \max\{f(x - z) + s(z) | z \in S\}
\]

Here, \( S \) is the domain of the structuring element \( s \) (see read_gray_se).

The gray value dilation is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

Parameters

- **Image** (input_object) ... (multichannel-)image-array \( \sim \) object : byte / uint2 / real
  Input image.
- **SE** (input_object) ... singlechannelimage \( \sim \) object : byte / uint2 / real
  Structuring element.
- **ImageDilation** (output_object) ... (multichannel-)image-array \( \sim \) object : byte / uint2 / real
  Gray-dilated image.

Result

gray_dilation returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Module

gray_dilation_rect ( Image : ImageMax : MaskHeight, MaskWidth : )

Determine the maximum gray value within a rectangle.

gray_dilation_rect calculates the maximum gray value of the input image Image within a rectangular mask of size (MaskHeight, MaskWidth) for each image point. The resulting image is returned in ImageMax. If the parameters MaskHeight or MaskWidth are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) ............................................................ (multichannel-)image(-array) ~ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  Image for which the maximum gray values are to be calculated.

- **ImageMax** (output_object) .................................................... (multichannel-)image(-array) ~ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  Image containing the maximum gray values.

- **MaskHeight** (input_control) .................................................. extent.y ~ integer
  Height of the filter mask.
  Default value: 11
  Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}
  Typical range of values: 3 ≤ MaskHeight ≤ 511
  Minimum increment: 2
  Recommended increment: 2
  Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2

- **MaskWidth** (input_control) .................................................... extent.x ~ integer
  Width of the filter mask.
  Default value: 11
  Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}
  Typical range of values: 3 ≤ MaskWidth ≤ 511
  Minimum increment: 2
  Recommended increment: 2
  Restriction: odd(MaskWidth) && MaskWidth < width(Image) * 2

Result

gray_dilation_rect returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(‘no_object_result’,<Result>). If necessary, an exception is raised.

Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

gray_skeleton

Module

Foundation

gray_dilation_shape ( Image : ImageMax : MaskHeight, MaskWidth,

                      MaskShape : )

Determine the maximum gray value within a selected mask.

gray_dilation_shape calculates the maximum gray value of the input image Image within a mask of shape MaskShape, vertical size MaskHeight and horizontal size MaskWidth for each image point. The resulting image is returned in ImageMax.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageMax is interpolated from the two intermediate images. Therefore, note that gray_dilation_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values 'rhombus' and 'octagon' for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value 'octagon' for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

Attention Note that gray_dilation_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_dilation_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ Image (input_object) ...................................................(multichannel)-image(-array) ~ object : byte / uint2
  Image for which the maximum gray values are to be calculated.

▷ ImageMax (output_object) .................................(multichannel)-image(-array) ~ object : byte / uint2
  Image containing the maximum gray values.

▷ MaskHeight (input_control) ...............................extent.y ~ real / integer
  Height of the filter mask.
  Default value: 11
  Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}
  Typical range of values: 1.0 ≤ MaskHeight

▷ MaskWidth (input_control) ...............................extent.x ~ real / integer
  Width of the filter mask.
  Default value: 11
  Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}
  Typical range of values: 1.0 ≤ MaskWidth

▷ MaskShape (input_control) .................................string ~ string
  Shape of the mask.
  Default value: 'octagon'
  List of values: MaskShape ∈ {'rectangle', 'rhombus', 'octagon' }
20.1. GRAY VALUES

gray_dilation_shape returns 2 (H_MSG_TRUE) if all parameters are correct.

Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

gray_dilation, gray_dilation_rect

gray_opening_shape, gray_closing_shape, gray_skeleton

Module

gray_erosion ( Image, SE : ImageErosion : : )

Perform a gray value erosion on an image.

gray_erosion applies a gray value erosion to the input image Image with the structuring element SE. The image type of the structuring element SE must match the image type of the input image Image. The gray value erosion of an image i with a structuring element s at the pixel position x is defined as:

\[(i \ominus s)(x) = \min\{f(x + z) - s(z) | z \in S\}\]

Here, S is the domain of the structuring element s (see read_gray_se).

The gray value erosion is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

Parameters

- Image (input_object) .......... (multichannel-image-array) \( \sim \) object : byte / uint2 / real Input image.
- SE (input_object) ................. singlechannelimage \( \sim \) object : byte / uint2 / real Structuring element.
- ImageErosion (output_object) .......... (multichannel-image-array) \( \sim \) object : byte / uint2 / real Gray-eroded image.

Result

gray_erosion returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

---

### gray_erosion_rect ( Image : ImageMin : MaskHeight, MaskWidth : )

Determine the minimum gray value within a rectangle.

gray_erosion_rect calculates the minimum gray value of the input image `Image` within a rectangular mask of size `(MaskHeight, MaskWidth)` for each image point. The resulting image is returned in `ImageMin`. If the parameters `MaskHeight` or `MaskWidth` are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

**Attention**
Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

**Parameters**

- **Image** (input_object) ...... (multichannel-)image(-array) ↼ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  Image for which the minimum gray values are to be calculated.

- **ImageMin** (output_object) ...... (multichannel-)image(-array) ↼ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  Image containing the minimum gray values.

- **MaskHeight** (input_control) .......................................................... extent.y ↼ integer
  Height of the filter mask.
  Default value: 11
  Suggested values: `MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}`
  Typical range of values: `3 ≤ MaskHeight ≤ 511` (lin)
  Minimum increment: 2
  Recommended increment: 2
  Restriction: `odd(MaskHeight) && MaskHeight < height(Image) * 2`

- **MaskWidth** (input_control) .......................................................... extent.x ↼ integer
  Width of the filter mask.
  Default value: 11
  Suggested values: `MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}`
  Typical range of values: `3 ≤ MaskWidth ≤ 511` (lin)
  Minimum increment: 2
  Recommended increment: 2
  Restriction: `odd(MaskWidth) && MaskWidth < width(Image) * 2`

**Result**
gray_erosion_rect returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

**Parallelization**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module Foundation

<table>
<thead>
<tr>
<th>gray_erosion_shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>( Image : ImageMin : MaskHeight, MaskWidth, MaskShape : )</td>
</tr>
</tbody>
</table>

Determine the minimum gray value within a selected mask.

gray_erosion_shape calculates the minimum gray value of the input image Image within a mask of shape MaskShape, vertical size MaskHeight and horizontal size MaskWidth for each image point. The resulting image is returned in ImageMin.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageMin is interpolated from the two intermediate images. Therefore, note that gray_erosion_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values ‘rhombus’ and ‘octagon’ for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value ‘octagon’ for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

Attention

Note that gray_erosion_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_erosion_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) (multichannel-image-array) ~ object : byte / uint2
  Image for which the minimum gray values are to be calculated.

- **ImageMin** (output_object) (multichannel-image-array) ~ object : byte / uint2
  Image containing the minimum gray values.

- **MaskHeight** (input_control) extent.y ~ real / integer
  Height of the filter mask.
  Default value: 11
  Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}
  Typical range of values: 1.0 ≤ MaskHeight

- **MaskWidth** (input_control) extent.x ~ real / integer
  Width of the filter mask.
  Default value: 11
  Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}
  Typical range of values: 1.0 ≤ MaskWidth

- **MaskShape** (input_control) string ~ string
  Shape of the mask.
  Default value: ‘octagon’
  List of values: MaskShape ∈ [‘rectangle’, ‘rhombus’, ‘octagon’]

Result

gray_erosion_shape returns 2 (H_MSG_TRUE) if all parameters are correct.
Parallelization

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module Foundation

gray_opening(Image, SE : ImageOpening : : )

Perform a gray value opening on an image.

gray_opening applies a gray value opening to the input image Image with the structuring element SE. The image type of the structuring element SE must match the image type of the input image Image. The gray value opening of an image i with a structuring element s is defined as

\[ i \circ s = (i \ominus s) \oplus \hat{s}, \]

i.e., an erosion of the image with s followed by a dilation with the transposed structuring element (see gray_erosion and gray_dilation). For the generation of structuring elements, see read_gray_se.

The gray value opening is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

Parameters

- **Image** (input_object) (multichannel-image-array) \sim object : byte / uint2 / real
  
  Input image.
- **SE** (input_object) (singlechannelimage) \sim object : byte / uint2 / real
  
  Structuring element.
- **ImageOpening** (output_object) (multichannel-image-array) \sim object : byte / uint2 / real
  
  Gray-opened image.

Result

gray_opening returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module
Foundation

**gray_opening_rect** ( Image : ImageOpening : MaskHeight, MaskWidth : )

Perform a gray value opening with a rectangular mask.

`gray_opening_rect` applies a gray value opening to the input image `Image` with a rectangular mask of size `(MaskHeight, MaskWidth)`. The resulting image is returned in `ImageOpening`. If the parameters `MaskHeight` or `MaskWidth` are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

The gray value opening of an image `i` with a rectangular structuring element `s` is defined as

\[ i \circ s = (i \ominus s) \oplus s , \]

i.e., an erosion of the image with `s` followed by a dilation with `s` (see `gray_erosion_rect` and `gray_dilation_rect`).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter **Filters**.

Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Input image.

- **ImageOpening** (output_object) ...... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Gray-opened image.

- **MaskHeight** (input_control) .................. extent.y \(\sim\) integer
  
  Height of the filter mask.
  
  Default value: 11
  
  Suggested values: `MaskHeight \in \{3, 5, 7, 9, 11, 13, 15\}`
  
  Typical range of values: `3 \leq MaskHeight \leq 511`
  
  Minimum increment: 2
  
  Recommended increment: 2
  
  Restriction: odd(`MaskHeight`) && `MaskHeight < height(Image) * 2`

- **MaskWidth** (input_control) .................. extent.x \(\sim\) integer
  
  Width of the filter mask.
  
  Default value: 11
  
  Suggested values: `MaskWidth \in \{3, 5, 7, 9, 11, 13, 15\}`
  
  Typical range of values: `3 \leq MaskWidth \leq 511`
  
  Minimum increment: 2
  
  Recommended increment: 2
  
  Restriction: odd(`MaskWidth`) && `MaskWidth < width(Image) * 2`

Result

`gray_opening_rect` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Parallelization

Module
Foundation

gray_opening_shape ( Image : ImageOpening : MaskHeight, MaskWidth, MaskShape : )

Perform a gray value opening with a selected mask.

gray_opening_shape applies a gray value opening to the input image Image with the structuring element of shape MaskShape. The mask’s offset values are 0 and its horizontal and vertical size is defined by MaskHeight and MaskWidth. The resulting image is returned in ImageOpening.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageOpening is interpolated from the two intermediate images. Therefore, note that gray_opening_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values ‘rhombus’ and ‘octagon’ for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value ‘octagon’ for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

The gray value opening of an image \( i \) with a structuring element \( s \) is defined as

\[
 i \circ s = (i \ominus s) \oplus s,
\]

i.e., an erosion of the image with \( s \) followed by a dilation with \( s \) (see gray_erosion_shape and gray_dilation_shape).

Attention
Note that gray_opening_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_opening_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) .................. (multichannel-)image(-array) \( \sim \) object : byte / uint2
  Image for which the minimum gray values are to be calculated.

- **ImageOpening** (output_object) .............. (multichannel-)image(-array) \( \sim \) object : byte / uint2
  Image containing the minimum gray values.

- **MaskHeight** (input_control) ........................ extent.y \( \sim \) real / integer
  Height of the filter mask.

  Default value: 11

  Suggested values: \( \text{MaskHeight} \in [3, 5, 7, 9, 11, 13, 15] \)

  Typical range of values: \( 1.0 \leq \text{MaskHeight} \leq 511.0 \)

**read_gray_se** ( : SE : FileName : )

Load a structuring element for gray morphology.

read_gray_se loads a structuring element for gray morphology from a file. The file names of these structuring elements must end in '.gse' (for gray-scale structuring element). This suffix is automatically appended by read_gray_se to the passed file name, and thus must not be passed. The structuring element’s data must be contained in the file in the following format: The first line specifies the data type of the structuring element as 'byte', 'uint2' or 'real' (without enclosing quotes). It must match the image type of the image to be processed in subsequent operator calls using this structuring element. The following two numbers in the file determine the width and height of the structuring element and determine a rectangle enclosing the structuring element. Both values must be greater than 0. Then the number of chords of the region to be defined follows. Then the chords themselves follow: Each chord is defined by the row of the chord (L), the column begin (CB) and the column end (CE), separated by a space between them. Then values follow that are regarded as the corresponding values for gray morphology (their number depends on the defined width and height of the structuring element). Values that will not be part of the region of the structuring element (because no chord is defined for this point) must not be omitted. Nevertheless they will be ignored in the resulting structuring element. Structuring elements are stored internally as images with the data type specified above. Normal images can also be used as structuring elements, where the region of the image defines the shape of the structuring element. However, take care not to use too large images, since the runtime is proportional to the area of the image multiplied by the area of the structuring element. Flat structuring elements (i.e. elements with constant grayvalues) will be executed particularly fast though. The origin of the structuring element lies at half of the defined width and height. For even dimensions the origin will be rounded towards the upper left corner. The structuring element can be saved as image with the help of the operator write_image. However, take care to use an image format that supports alpha channels to save the shape of the structuring element such as 'tiff', 'jp2' or 'png'. These files can then be loaded again with the operator read_image.

---

**Parameters**

- **SE** (output_object) ........................................... image \( \sim \) object : byte / uint2 / real
  
  Generated structuring element.

- **FileName** (input_control) ........................................... filename.read \( \sim \) string
  
  Name of the file containing the structuring element.

  **File extension:** .gse

---

**Example**

* Load a byte structuring element of width 3 and height 3 that
* consists of 3 chords at lines 0 (from x=1 to x=1), 1 (from x=0
* to x=2) and 2 (from x=1 to x=1). The (used) grayvalues are
* 0, 0, 1, 0, 0.

20.2 Region

This chapter describes operators of region morphology.

Concept of Region Morphology

Region morphology provides a set of morphological operators that allow to modify or describe the shape of a region. The morphological operators can be used, for example, to connect or disconnect adjacent regions or to smooth the boundary of a region. In the following, we will take a closer look at the morphological operators.

Dilation and Erosion

To dilate or erode an input region, a structuring element is applied to the input region. This structuring element is scanned over the image line-by-line. During dilation the reference point of the structuring element is added to the resulting region whenever the structuring element and the input region have at least one pixel in common. This results in an enlarged region, as shown in the image below. Erosion reduces the area of the input region because the reference point is only added to the resulting region if the structuring element lies completely within the input region. As a result, erosion can alternatively be used to find objects.
These operators can be used to dilate or erode a region:

<table>
<thead>
<tr>
<th>Morphological Operators</th>
<th>Structuring Element</th>
<th>Reference Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>dilation1</td>
<td>erosion1</td>
<td>arbitrary</td>
</tr>
<tr>
<td>minkowski_add1</td>
<td>minkowski_sub1</td>
<td>arbitrary, transposed</td>
</tr>
<tr>
<td>dilation2</td>
<td>erosion2</td>
<td>arbitrary, transposed</td>
</tr>
<tr>
<td>minkowski_add2</td>
<td>minkowski_sub2</td>
<td>arbitrary, transposed</td>
</tr>
<tr>
<td>dilation_circle</td>
<td>erosion_circle</td>
<td>circular, origin</td>
</tr>
<tr>
<td>dilation_rectangle1</td>
<td>erosion_rectangle1</td>
<td>rectangular, origin</td>
</tr>
</tbody>
</table>

Note that Minkowski addition and dilation are identical if the structuring element is symmetric. The same applies to Minkowski subtraction and erosion. Erosion can be used to separate objects that are attached to each other. In the following, the steps that are required to separate objects are described briefly.

First, the objects of the image must be segmented, for example by using the operator `threshold`. Next, the operator `connection` is used to get multiple regions instead of a single region. As you can see in the image (3) below, the result of the connection is unsatisfactory because several objects are merged.

This problem can be solved using erosion. As mentioned above, erosion reduces the area of the input region. Thus, if erosion is applied prior to the operator `connection`, the regions are separated as desired. Lastly, dilation is applied on the separated regions to approximately get the original shape back.
Opening and Closing

Both operators generate the resulting region by combining dilation and erosion. Opening is an erosion followed by a dilation. It is useful to eliminate small unwanted structures. Closing is the opposite of opening, i.e., a dilation followed by an erosion. The closing operator is able to close small gaps, as shown below.

![Opening and Closing Diagram](image)

(1) Image with input region, (2) structuring element with reference point, (3) result of applying an opening to the input region, (4) result of applying a closing.

These operators can be used to open or close a region:

<table>
<thead>
<tr>
<th>Morphological Operators</th>
<th>Structuring Element</th>
<th>Reference Point</th>
</tr>
</thead>
<tbody>
<tr>
<td>opening</td>
<td>closing</td>
<td>arbitrary</td>
</tr>
<tr>
<td>opening_circle</td>
<td>closing_circle</td>
<td>circular</td>
</tr>
<tr>
<td>opening_rectangle</td>
<td>closing_rectangle</td>
<td>rectangular</td>
</tr>
</tbody>
</table>

Further Operators

In addition to the operators mentioned above, you can use top_hat to get the difference between the input region and the result of the opening, or bottom_hat to get the difference between the result of the closing and the input region. Furthermore, you can calculate the boundary of a region with the operator boundary.

![Further Operators Diagram](image)

(1) Top hat, (2) bottom hat, (3) boundary.

The operator hit_or_miss can be used to find objects, taking the foreground and the background of the image into account. To remove unwanted branches from a skeleton, pruning is a suitable operator.

Glossary

In the following list, the most important terms that are used in the context of Morphology are described.

- **input region** Region which is modified by morphological operators.
- **structuring element** Region which is used to scan the input region.

```
bottom_hat ( Region, StructElement : RegionBottomHat : : )
```

Compute the bottom hat of regions.
bottom_hat computes the closing of Region with StructElement. The difference between the result of the closing and the original region is called the bottom hat. In contrast to closing, which merges regions under certain circumstances, bottom_hat computes the regions generated by such a merge.

The position of StructElement is meaningless, since a closing operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

---

**Parameters**

- Region (input_object) \(\rightarrow\) object Regions to be processed.
- StructElement (input_object) \(\rightarrow\) object Structuring element (position independent).
- RegionBottomHat (output_object) \(\rightarrow\) object Result of the bottom hat operator.

---

**Example**

```halcon
read_image(Image, 'brake_disk/brake_disk_bike_01')
threshold(Image, Regions, 128, 255)
gen_circle(Circle, 40, 40, 20)
bottom_hat(Regions, Circle, RegionBottomHat)
```

---

**Result**

bottom_hat returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```halcon
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```halcon
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

Foundation
boundary ( Region : RegionBorder : BoundaryType : )

Reduce a region to its boundary.

boundary computes the boundary of each input region in Region and returns them in RegionBorder. The parameter BoundaryType determines the type of boundary computation.

The contour computation is done using morphological operations. The resulting output regions consist only of the minimal border of the input regions. Their positions depend on the value of BoundaryType, accepting the following values:

- 'inner': The contour lies within the original region.
- 'inner_filled': The contour lies within the original region, holes in the interior of the input region are suppressed. Due to algorithm optimization this contours may slightly differ from corresponding ones obtained with 'inner'.
- 'outer': The contour is one pixel outside of the original region.

### Parameters

<table>
<thead>
<tr>
<th>Region (input_object)</th>
<th>region(-array)</th>
<th>object Regions for which the boundary is to be computed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegionBorder (output_object)</td>
<td>region(-array)</td>
<td>object Resulting boundaries.</td>
</tr>
<tr>
<td>BoundaryType (input_control)</td>
<td>string</td>
<td>string Boundary type.</td>
</tr>
</tbody>
</table>

**Default value:** 'inner'

**List of values:** BoundaryType ∈ {'inner', 'outer', 'inner_filled'}

### Example

```cpp
#include "HalconCpp.h"
using namespace Halcon;

main()
{
    HWindow w;
    HRegion circ1 = HRegion::GenCircle (20, 10, 10.5);

    circ1.Display (w);
    w.Click ();

    HRegion marg1 = circ1.Boundary ("inner");
    w.SetColor ("red");
    marg1.Display (w);
    w.Click ();

    return(0);
}
```

### Complexity

Let $A$ be the area of the input region. Then the runtime complexity for one region is

$$O(3\sqrt{A})$$

### Result

boundary returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```cpp
  set_system('no_object_result',<RegionResult>)
  ```
• empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

---

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

fill_up

Module
Foundation

```c
closing ( Region, StructElement : RegionClosing : : )
```

Close a region.

A closing operation is defined as a dilation followed by a Minkowski subtraction. By applying `closing` to a region, larger structures remain mostly intact, while small gaps between adjacent regions and holes smaller than `StructElement` are closed, and the regions’ boundaries are smoothed. All closing variants share the property that separate regions are not merged, but remain separate objects. The position of `StructElement` is meaningless, since a closing operation is invariant with respect to the choice of the reference point.

Structuring elements (`StructElement`) can be generated with operators such as `gen_circle`, `gen_rectangle1`, `gen_rectangle2`, `gen_ellipse`, `draw_region`, `gen_region_polygon`, `gen_region_points`, etc.

Attention: `closing` is applied to each input region separately. If gaps between different regions are to be closed, `union1` or `union2` has to be called first.

**Parameters**

- **Region** (input_object) .............................. region(-array)  object
  Regions to be closed.
- **StructElement** (input_object) ................. region  object
  Structuring element (position-invariant).
- **RegionClosing** (output_object) .............. region(-array)  object
  Closed regions.

Example

```c
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
```
cout << "Reproduction of 'closing ()' using " << endl;
cout << "'dilation()' and 'minkowski_sub1()'" << endl;

HByteImage img("monkey");
HWindow w;

HRegion circ = HRegion::GenCircle (10, 10, 1.5);
HRegionArray regs = (img >= 128).Connection();

HRegionArray dilreg = regs.Dilation1 (circ, 1);
HRegionArray minsub = dilreg.MinkowskiSub1 (circ, 1);

img.Display (w); w.Click ();
w.SetColor ("red"); regs.Display (w); w.Click ();
w.SetColor ("green"); dilreg.Display (w); w.Click ();
w.SetColor ("blue"); minsub.Display (w); w.Click ();

return(0);

---

Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F_1} \cdot \sqrt{F_2})$$

---

Result

closing returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result', <RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result', <RegionResult>)
  ```

Otherwise, an exception is raised.

Module

Foundation
**closing_circle** ( Region : RegionClosing : Radius : )

**Close a region with a circular structuring element.**

closing_circle behaves analogously to **closing**, i.e., the regions' boundaries are smoothed and holes within a region which are smaller than the circular structuring element of radius **Radius** are closed. The closing_circle operation is defined as a dilation followed by a Minkowski subtraction, both with the same circular structuring element.

____________ Attention ______________

closing_circle is applied to each input region separately. If gaps between different regions are to be closed, **union1** or **union2** has to be called first.

____________ Parameters ______________

▷ **Region** (input_object) ................................. region(-array) ➔ object
   Regions to be closed.

▷ **RegionClosing** (output_object) .......................... region(-array) ➔ object
   Closed regions.

▷ **Radius** (input_control) ................................. real ➔ real / integer
   Radius of the circular structuring element.
   Default value: 3.5
   Suggested values: **Radius** ∈ {1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5}
   Typical range of values: 0.5 ≤ **Radius** ≤ 511.5 (lin)
   Minimum increment: 1.0
   Recommended increment: 1.0

____________ Example ______________

```c
my_closing_circle(Hobject In, double Radius, Hobject *Out)
{
    Hobject tmp, StructElement;
    gen_circle(StructElement,100.0,100.0,Radius);
    dilation1(In,StructElement,&tmp,1);
    minkowski_sub1(tmp,StructElement,Out,1);
}
```

____________ Complexity ______________

Let **F1** be the area of the input region. Then the runtime complexity for one region is:

```
O(4 · √F1 · **Radius**).
```

____________ Result ______________

closing_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```c
  set_system('no_object_result',<RegionResult>)
  ```

- empty region:
  ```c
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

____________ Parallelization ______________

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module
Foundation

closing_rectangle1 ( Region : RegionClosing : Width, Height : )

Close a region with a rectangular structuring element.

closing_rectangle1 performs a dilation_rectangle1 followed by an erosion_rectangle1 on the input region Region. The size of the rectangular structuring element is determined by the parameters Width and Height. As is the case for all closing variants, regions’ boundaries are smoothed and holes within a region which are smaller than the rectangular structuring element are closed.

Attention
closing_rectangle1 is applied to each input region separately. If gaps between different regions are to be closed, union_1 or union_2 has to be called first.

Parameters

▷ Region (input_object) .................................................. region(-array) \( \sim \) object
Regions to be closed.

▷ RegionClosing (output_object) ................ region(-array) \( \sim \) object
Closed regions.

▷ Width (input_control) .............................................. extent.x \( \sim \) integer
Width of the structuring rectangle.
   Default value: 10
   Suggested values: Width \( \in \) \{1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200\}
   Typical range of values: \( 1 \leq \text{Width} \leq 511 \) (lin)

   Minimum increment: 1
   Recommended increment: 1

▷ Height (input_control) .......................................... extent.y \( \sim \) integer
Height of the structuring rectangle.
   Default value: 10
   Suggested values: Height \( \in \) \{1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200\}
   Typical range of values: \( 1 \leq \text{Height} \leq 511 \) (lin)

   Minimum increment: 1
   Recommended increment: 1

Complexity

Let \( F_1 \) be the area of an input region and \( H \) be the height of the rectangle. Then the runtime complexity for one region is:

\[
O(2 \cdot \sqrt{F_1} \cdot \log_2(H))
\]

Result
closing_rectangle1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system(‘no_object_result’,<RegionResult>)
• empty region:
  ```plaintext
system('empty_region_result',<RegionResult>)
```
Otherwise, an exception is raised.

**dilation1** ( Region, StructElement : RegionDilation : Iterations : )

Dilate a region.

dilation1 dilates the input regions with a structuring element. By applying dilation1 to a region, its boundary gets smoothed. In the process, the area of the region is enlarged. Furthermore, disconnected regions may be merged. Such regions, however, remain logically distinct region. The dilation is a set-theoretic region operation. It uses the union operation.

Let \( M (\text{StructElement}) \) and \( R (\text{Region}) \) be two regions, where \( M \) is the structuring element and \( R \) is the region to be processed. Furthermore, let \( m \) be a point in \( M \). Then the displacement vector \( \vec{v}_m = (dx, dy) \) is defined as the difference of the center of gravity of \( M \) and the vector \( \vec{m} \). Let \( \tilde{t}_{\vec{v}}(R) \) denote the translation of a region \( R \) by a vector \( \vec{v} \). Then

\[
\text{dilation1}(R, M) := \bigcup_{m \in M} \tilde{t}_{\vec{v}_m}(R)
\]

For each point \( m \) in \( M \) a translation of the region \( R \) is performed. The union of all these translations is the dilation of \( R \) with \( M \). dilation1 is similar to the operator minkowski_add1, the difference is that in dilation1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of \( M \).

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \). From the above definition it follows that an empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

---

**Attention**

A dilation always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.
### Parameters

- **Region** (input_object) .. region(-array) ~ object
  Regions to be dilated.
- **StructElement** (input_object) .. region ~ object
  Structuring element.
- **RegionDilation** (output_object) .. region(-array) ~ object
  Dilated regions.
- **Iterations** (input_control) .. integer ~ integer
  Number of iterations.
  **Default value:** 1
  **Suggested values:** Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
  **Typical range of values:** 1 ≤ Iterations (lin)
  **Minimum increment:** 1
  **Recommended increment:** 1

### Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})$$.

### Result

dilation1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:** `set_system('no_object_result',<RegionResult>)`
- **empty region:** `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

### Possible Successors

### Module

Foundation

#### dilation2 ( Region, StructElement : RegionDilation : Row, Column, Iterations : )

Dilate a region (using a reference point).

dilation2 dilates the input regions with a structuring element (StructElement) having the reference point (Row,Column). dilation2 has a similar effect as dilation1, the difference is that the reference point of the
structuring element can be chosen arbitrarily. The parameter \textit{Iterations} determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \).

An empty region is generated in case of an empty structuring element.

Structuring elements (\textit{StructElement}) can be generated with operators such as \texttt{gen
circle}, \texttt{gen rectangle1}, \texttt{gen rectangle2}, \texttt{gen ellipse}, \texttt{draw region}, \texttt{gen region polygon}, \texttt{gen region points}, etc.

\begin{itemize}
\item \textbf{Attention}:
\end{itemize}

A dilation always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator \texttt{union1} has to be called first.

\begin{itemize}
\item \textbf{Parameters}:
\end{itemize}

\begin{itemize}
\item \texttt{Region} (input\_object) \rightarrow \texttt{region(-array)} \rightarrow \texttt{object}
\item Regions to be dilated.
\item \texttt{StructElement} (input\_object) \rightarrow \texttt{region(-array)} \rightarrow \texttt{object}
\item Structuring element.
\item \texttt{RegionDilation} (output\_object) \rightarrow \texttt{region(-array)} \rightarrow \texttt{object}
\item Dilated regions.
\item \texttt{Row} (input\_control) \rightarrow \texttt{point.y} \rightarrow \texttt{integer}
\item Row coordinate of the reference point.
\item Default value: \( 0 \)
\item \texttt{Column} (input\_control) \rightarrow \texttt{point.x} \rightarrow \texttt{integer}
\item Column coordinate of the reference point.
\item Default value: \( 0 \)
\item \texttt{Iterations} (input\_control) \rightarrow \texttt{integer} \rightarrow \texttt{integer}
\item Number of iterations.
\item Default value: \( 1 \)
\item Suggested values: \( \texttt{Iterations} \in \{ 1, 2, 3, 4, 5, 7, 11, 17, 25, 32, 64, 128 \} \)
\item Typical range of values: \( 1 \leq \texttt{Iterations} \) (lin)
\item Minimum increment: \( 1 \)
\item Recommended increment: \( 1 \)
\end{itemize}

\begin{itemize}
\item \textbf{Complexity}:
\end{itemize}

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[ O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \texttt{Iterations}) \]

\begin{itemize}
\item \textbf{Result}:
\end{itemize}

dilation2 returns \( 2 \) (\texttt{H\_MSG\_TRUE}) if all parameters are correct. The behavior in case of empty or no input region can be set via:

\begin{itemize}
\item no region:
\begin{verbatim}
set_system('no_object_result',<RegionResult>)
\end{verbatim}
\item empty region:
\begin{verbatim}
set_system('empty_region_result',<RegionResult>)
\end{verbatim}
\end{itemize}

Otherwise, an exception is raised.

\begin{itemize}
\item \textbf{Parallelization}:
\end{itemize}

\begin{itemize}
\item Multithreading type: reentrant (runs in parallel with non-exclusive operators).
\item Multithreading scope: global (may be called from any thread).
\item Automatically parallelized on tuple level.
\end{itemize}

---

**dilation_circle** ( Region : RegionDilation : Radius : )

_Dilate a region with a circular structuring element._

dilation_circle applies a Minkowski addition with a circular structuring element to the input regions Region. Because the circular mask is symmetrical, this is identical to a dilation. The size of the circle used as structuring element is determined by Radius.

The operator results in enlarged regions, smoothed region boundaries, and the holes smaller than the circular mask in the interior of the region are closed. It is useful to select only values like 3.5, 5.5, etc. for Radius in order to avoid a translation of a region, because integer radii result in the circle having a non-integer center of gravity which is rounded to the next integer.

**Attention**

dilation_circle is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

**Parameters**

- **Region** (input_object) region(-array) object
  Regions to be dilated.
- **RegionDilation** (output_object) region(-array) object
  Dilated regions.
- **Radius** (input_control) real / integer
  Radius of the circular structuring element.
  Default value: 3.5
  Suggested values: Radius ∈ {1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5}
  Typical range of values: 0.5 ≤ Radius ≤ 511.5 (lin)
  Minimum increment: 1.0
  Recommended increment: 1.0

**Example**

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
  cout << "Reproduction of 'dilation_circle ()'" << endl;
  cout << "First = original image " << endl;
  cout << "Blue = after dilation " << endl;
  cout << "Red = before dilation " << endl;
```

---

**Foundation**
HByteImage img("monkey");
HWindow w;

HRegion circ = HRegion::GenCircle (10, 10, 1.5);
HRegionArray regs = (img >= 128).Connection();
HRegionArray minadd = regs.MinkowskiAdd1 (circ, 1);

img.Display (w); w.Click ();
w.SetColor ("blue"); minadd.Display (w); w.Click ();
w.SetColor ("red"); regs.Display (w); w.Click ();
return(0);

Complexity

Let $F_1$ be the area of an input region. Then the runtime complexity for one region is:

$$O(2 \cdot \text{Radius} \cdot \sqrt{F_1}).$$

Result
dilation_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors
threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

Possible Successors
reduce_domain, select_shape, area_center, connection

Alternatives

dilation_rectangle

See also
gen_circle, erosion_circle, closing_circle, opening_circle

Foundation

dilation_rectangle ( Region : RegionDilation : Width, Height : )

Dilate a region with a rectangular structuring element.
dilation_rectangle applies a dilation with a rectangular structuring element to the input regions Region. The size of the structuring rectangle is $\text{Width} \times \text{Height}$. The operator results in enlarged regions, and the holes smaller than the rectangular mask in the interior of the regions are closed.
dilation_rectangle1 is a very fast operation because the height of the rectangle enters only logarithmically into the runtime complexity, while the width does not enter at all. This leads to excellent runtime efficiency, even in the case of very large rectangles (edge length > 100).

Attention
dilation_rectangle1 is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

To enlarge a region by the same amount in all directions, Width and Height must be odd. If this is not the case, the region is dilated by a larger amount at the right or at the bottom, respectively, than at the left or at the top.

Example

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
main()
{
    cout << "Reproduction of 'dilation_rectangle ()'" << endl;
    cout << "First = original image " << endl;
    cout << "Blue = after dilation " << endl;
    cout << "Red = after segmentation " << endl;

    HByteImage img("monkey");
    HWindow w;

    HRegionArray regs = (img >= 220).Connection();
    HRegionArray dilreg = regs.DilationRectangle1 (2, 4);

    img.Display (w); w.Click ();
    w.SetColor ("blue"); dilreg.Display (w); w.Click ();
    w.SetColor ("red"); regs.Display (w); w.Click ();

    return(0);
}
```

Complexity

Let $F_1$ be the area of an input region and $H$ be the height of the rectangle. Then the runtime complexity for one region is:
\[
O(\sqrt{F} \cdot \text{ld}(H))
\]

**dilation_rectangle**: returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  ```
  set_system('no_object_result',<RegionResult>)
  ```

- empty region:
  
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Predecessors**

- threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

**Possible Successors**

- reduce_domain, select_shape, area_center, connection

**Alternatives**

- minkowski_add1, minkowski_add2, expand_region, dilation1, dilation2, dilation_circle

**See also**

- gen_rectangle1, gen_region_polygon_filled

**Module**

**erosion1** (Region, StructElement : RegionErosion : Iterations : )

**Erode a region.**

`erosion1` erodes the input regions with a structuring element. By applying `erosion1` to a region, its boundary gets smoothed. In the process, the area of the region is reduced. Furthermore, connected regions may be split. Such regions, however, remain logically one region. The erosion is a set-theoretic region operation. It uses the intersection operation.

Let \( M \) (StructElement) and \( R \) (Region) be two regions, where \( M \) is the structuring element and \( R \) is the region to be processed. Furthermore, let \( m \) be a point in \( M \). Then the displacement vector \( \vec{v}_m = (dx, dy) \) is defined as the difference of the center of gravity of \( M \) and the vector \( \vec{m} \). Let \( t_{-\vec{v}_m}(R) \) denote the translation of a region \( R \) by a vector \( \vec{v}_m \). Then

\[
\text{erosion1}(R,M) := \bigcap_{m \in M} t_{-\vec{v}_m}(R).
\]

For each point \( m \) in \( M \) a translation of the region \( R \) is performed. The intersection of all these translations is the erosion of \( R \) with \( M \). `erosion1` is similar to the operator `minkowski_sub1`, the difference is that in `erosion1` the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of \( M \).

The parameter `Iterations` determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \). From the above definition it follows that the maximum region is generated in case of an empty structuring element.
Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

--- Parameters ---

▷ Region (input_object) .................................................. region(-array) ~ object

- Regions to be eroded.

▷ StructElement (input_object) ........................................ region ~ object

- Structuring element.

▷ RegionErosion (output_object) ..................................... region(-array) ~ object

- Eroded regions.

▷ Iterations (input_control) ............................................ integer ~ integer

- Number of iterations.

  Default value: 1

  Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}

  Typical range of values: 1 ≤ Iterations (lin)

  Minimum increment: 1

  Recommended increment: 1

--- Complexity ---

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})$$.

--- Result ---

erosion1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)

- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

--- Module ---

Foundation
erosion2 ( Region, StructElement : RegionErosion : Row, Column, Iterations : )

Erode a region (using a reference point).

erosion2 erodes the input regions with a structuring element (StructElement) having the reference point (Row,Column). erosion2 has a similar effect as erosion1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \).

A maximum region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

**Parameters**

- **Region** (input_object) : region(-array) \( \leadsto \) object
  Regions to be eroded.
- **StructElement** (input_object) : region
  Structuring element.
- **RegionErosion** (output_object) : region(-array) \( \leadsto \) object
  Eroded regions.
- **Row** (input_control) : point.y \( \leadsto \) integer
  Row coordinate of the reference point.
  Default value: 0
  Typical range of values: \( 0 \leq \text{Row} \leq 511 \) (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Column** (input_control) : point.x \( \leadsto \) integer
  Column coordinate of the reference point.
  Default value: 0
  Typical range of values: \( 0 \leq \text{Column} \leq 511 \) (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Iterations** (input_control) : integer \( \leadsto \) integer
  Number of iterations.
  Default value: 1
  Suggested values: \( \text{Iterations} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\} \)
  Typical range of values: \( 1 \leq \text{Iterations} \) (lin)
  Minimum increment: 1
  Recommended increment: 1

**Complexity**

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[
\mathcal{O}(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})
\]

**Result**

erosion2 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:**
  
  set_system('no_object_result',<RegionResult>)

- **empty region:**
  
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

**Parallelization**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

See also
transpose_region, gen_circle, gen_rectangle2, gen_region_polygon

Module
Foundation

**erosion_circle ( Region : RegionErosion : Radius : )**

Erode a region with a circular structuring element.

erosion_circle applies a Minkowski subtraction with a circular structuring element to the input regions Region. Because the circular mask is symmetrical, this is identical to an erosion. The size of the circle used as structuring element is determined by Radius.

The operator results in reduced regions, smoothed region boundaries, and the regions smaller than the circular mask are eliminated. It is useful to select only values like 3.5, 5.5, etc. for Radius in order to avoid a translation of a region, because integer radii result in a circle having a non-integer center of gravity which is rounded to the next integer.

**Parameters**

- **Region** (input_object) region(-array) \( \leadsto \) object
  Regions to be eroded.
- **RegionErosion** (output_object) region(-array) \( \leadsto \) object
  Eroded regions.
- **Radius** (input_control) real \( \leadsto \) real/integer
  Radius of the circular structuring element.
  Default value: 3.5
  Suggested values: Radius \( \in \{1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5\} \)
  Typical range of values: \( 0.5 \leq \text{Radius} \leq 511.5 \) (lin)
  Minimum increment: 1.0
  Recommended increment: 1.0

**Example**

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
  cout << "Simulation of 'erosion_circle ()'" << endl;
  cout << "First = original image " << endl;
  cout << "Red = after segmentation " << endl;
  cout << "Blue = after erosion " << endl;
```

HByteImage img("monkey");
HWindow w;

HRegion circ = HRegion::GenCircle (10, 10, 1.5);
HRegionArray regs = (img >= 128).Connection();
HRegionArray minsub = regs.MinkowskiSub1 (circ, 1);

    img.Display (w);  w.Click ();
    w.SetColor ("red"); reg.Display (w);  w.Click ();
    w.SetColor ("blue"); minsub.Display (w); w.Click ();

return(0);

Complexity
Let \( F_1 \) be the area of an input region. Then the runtime complexity for one region is:

\[
O(2 \cdot \text{Radius} \cdot \sqrt{F_1}).
\]

Result
erosion_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Parallelization
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors
threshold, regiongrowing, watersheds, class_ndim_norm

Possible Successors
connection, reduce_domain, select_shape, area_center

Alternatives
minkowski_sub1

See also
gen_circle, dilation_circle, closing_circle, opening_circle

Module

erosion_rectangle1 ( Region : RegionErosion : Width, Height : )

Erode a region with a rectangular structuring element.

erosion_rectangle1 applies an erosion with a rectangular structuring element to the input regions Region.

The size of the structuring rectangle is Width x Height. The operator results in reduced regions, and the areas smaller than the rectangular mask are eliminated.
erosion_rectangle1 is a very fast operation because the height of the rectangle enters only logarithmically into the runtime complexity, while the width does not enter at all. This leads to excellent runtime efficiency, even in the case of very large rectangles (edge length > 100).

Regions containing small connecting strips between large areas are separated only seemingly. They remain logically one region.

Attention

To reduce a region by the same amount in all directions, Width and Height must be odd. If this is not the case, the region is eroded by a larger amount at the right or at the bottom, respectively, than at the left or at the top.

Parameters

- **Region** (input_object)  
  Regions to be eroded.  
  Region(-array)  
  object
- **RegionErosion** (output_object)  
  Eroded regions.  
  Region(-array)  
  object
- **Width** (input_control)  
  Width of the structuring rectangle.  
  Default value: 11
  Suggested values: Width ∈ {1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201}
  Typical range of values: 1 ≤ Width ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Height** (input_control)  
  Height of the structuring rectangle.  
  Default value: 11
  Suggested values: Height ∈ {1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201}
  Typical range of values: 1 ≤ Height ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1

Complexity

Let $F_1$ be the area of an input region and $H$ be the height of the rectangle. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \log(H))$$

Result

erosion_rectangle1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:**  
  set_system(‘no_object_result’,<RegionResult>)
- **empty region:**  
  set_system(‘empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, watersheds, class_ndim_norm

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

erosion1, minkowski_sub1
hit_or_miss ( Region, StructElement1, StructElement2 : RegionHitMiss : Row, Column : )

Hit-or-miss operation for regions.

hit_or_miss performs the hit-or-miss-transformation. First, an erosion with the structuring element StructElement1 is done on the input region Region. Then an erosion with the structuring element StructElement2 is performed on the complement of the input region. The intersection of the two resulting regions is the result RegionHitMiss of hit_or_miss.

The hit-or-miss-transformation selects precisely the points for which the conditions given by the structuring elements StructElement1 and StructElement2 are fulfilled. StructElement1 determines the condition for the foreground pixels, while StructElement2 determines the condition for the background pixels. In order to obtain sensible results, StructElement1 and StructElement2 must fit like key and lock. In any case, StructElement1 and StructElement2 must be disjunct. Row and Column determine the reference point of the structuring elements.

Structuring elements (StructElement1, StructElement2) can be generated by calling operators like gen_region_points, etc.

Parameters

- **Region** (input_object) : region(-array) ~ object
  Regions to be processed.

- **StructElement1** (input_object) : region ~ object
  Erosion mask for the input regions.

- **StructElement2** (input_object) : region ~ object
  Erosion mask for the complements of the input regions.

- **RegionHitMiss** (output_object) : region(-array) ~ object
  Result of the hit-or-miss operation.

- **Row** (input_control) : point.y ~ integer
  Row coordinate of the reference point.
  Default value: 16
  Suggested values: Row ∈ {0, 16, 32, 128, 256}
  Typical range of values: 0 ≤ Row ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1

- **Column** (input_control) : point.x ~ integer
  Column coordinate of the reference point.
  Default value: 16
  Suggested values: Column ∈ {0, 16, 32, 128, 256}
  Typical range of values: 0 ≤ Column ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1

Complexity

Let \( F \) be the area of an input region, \( F1 \) the area of the structuring element 1, and \( F2 \) the area of the structuring element 2. Then the runtime complexity for one object is:

\[
O \left( \sqrt{F} \cdot \left( \sqrt{F1} + \sqrt{F2} \right) \right)
\]

Result

hit_or_miss returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

HALCON 20.05.0.0
• no region:
  
  \[
  \text{set\_system('no\_object\_result',<RegionResult>)}
  \]

• empty region:

\[
\text{set\_system('empty\_region\_result',<RegionResult>)}
\]

Otherwise, an exception is raised.

### minkowski\_add1 (Region, StructElement : RegionMinkAdd : Iterations : )

**Perform a Minkowski addition on a region.**

minkowski\_add1 dilates the input regions with a structuring element. By applying minkowski\_add1 to a region, its boundary gets smoothed. In the process, the area of the region is enlarged. Furthermore, disconnected regions may be merged. Such regions, however, remain logically distinct region. The Minkowski addition is a set-theoretic region operation. It is based on translations and union operations.

Let \( M \) (StructElement) and \( R \) (Region) be two regions, where \( M \) is the structuring element and \( R \) is the region to be processed. Furthermore, let \( m \) be a point in \( M \). Then the displacement vector \( \vec{v}_m = (dx, dy) \) is defined as the difference of the center of gravity of \( M \) and the vector \( \vec{m} \). Let \( t_{\vec{v}_m}(R) \) denote the translation of a region \( R \) by a vector \( \vec{v} \). Then

\[
minkowski\_add1(R, M) := \bigcup_{m \in M} t_{\vec{v}_m}(R)
\]

For each point \( m \) in \( M \) a translation of the region \( R \) is performed. The union of all these translations is the Minkowski addition of \( R \) with \( M \). minkowski\_add1 is similar to the operator dilation1, the difference is that in dilation1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of \( M \).

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \). From the above definition it follows that an empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen\_circle, gen\_rectangle1, gen\_rectangle2, gen\_ellipse, draw\_region, gen\_region\_polygon, gen\_region\_points, etc.

---

**Attention**

A Minkowski addition always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.
Parameters

- **Region** (input_object) .......................................................... region(-array) \(\sim\) object
  Regions to be dilated.
- **StructElement** (input_object) .................................................. region \(\sim\) object
  Structuring element.
- **RegionMinkAdd** (output_object) .............................................. region(-array) \(\sim\) object
  Dilated regions.
- **Iterations** (input_control) .................................................... integer \(\sim\) integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations \(\in\) \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
  Typical range of values: \(1 \leq\) Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

Complexity

Let \(F_1\) be the area of the input region, and \(F_2\) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})
\]

Result

minkowski_add1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system(’no_object_result’,<RegionResult>)
- empty region:
  set_system(’empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

Foundation

minkowski_sub1 ( Region,
    StructElement : RegionMinkSub : Iterations : )

Erode a region.

minkowski_sub1 computes the Minkowski subtraction of the input regions with a structuring element. By applying minkowski_sub1 to a region, its boundary gets smoothed. In the process, the area of the region is reduced. Furthermore, connected regions may be split. Such regions, however, remain logically one region. The Minkowski subtraction is a set-theoretic region operation. It uses the intersection operation.

Let $M$ (StructElement) and $R$ (Region) be two regions, where $M$ is the structuring element and $R$ is the region to be processed. Furthermore, let $m$ be a point in $M$. Then the displacement vector $\vec{v}_m = (dx, dy)$ is defined as the difference of the center of gravity of $M$ and the vector $\vec{m}$. Let $t_{\vec{v}_m}(R)$ denote the translation of a region $R$ by a vector $\vec{v}$. Then

$$minkowski\_sub1(R, M) := \bigcap_{m \in M} t_{\vec{v}_m}(R)$$

For each point $m$ in $M$ a translation of the region $R$ is performed. The intersection of all these translations is the Minkowski subtraction of $R$ with $M$. minkowski_sub1 is similar to the operator erosion1, the difference is that in erosion1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of $M$.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration $n$. From the above definition it follows that the maximum region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

Module

Foundation

minkowski_sub2 ( Region, StructElement : RegionMinkSub : Row,
Column, Iterations : )

Erode a region (using a reference point).

minkowski_sub2 computes the Minkowski subtraction of the input regions with a structuring element (StructElement) having the reference point (Row,Column). minkowski_sub2 has a similar effect as minkowski_sub1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration $n$.

A maximum region is generated in case of an empty structuring element.
Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

### Parameters

- **Region** (input_object) -> object
  Regions to be eroded.

- **StructElement** (input_object) -> object
  Structuring element.

- **RegionMinkSub** (output_object) -> object
  Eroded regions.

- **Row** (input_control) -> integer
  Row coordinate of the reference point.
  Default value: 0
  Suggested values: Row ∈ {0, 10, 16, 32, 64, 100, 128}
  Typical range of values: 0 ≤ Row ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1

- **Column** (input_control) -> integer
  Column coordinate of the reference point.
  Default value: 0
  Suggested values: Column ∈ {0, 10, 16, 32, 64, 100, 128}
  Typical range of values: 0 ≤ Column ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1

- **Iterations** (input_control) -> integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
  Typical range of values: 1 ≤ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

### Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations}) .$$

### Result

minkowski_sub2 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```

- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

threshold, regiongrowing, watersheds, class_ndim_norm, gen_circle, gen_ellipse,
opening ( Region, StructElement : RegionOpening : : )

Open a region.

An opening operation is defined as an erosion followed by a Minkowski addition. By applying opening to a region, larger structures remain mostly intact, while small structures like lines or points are eliminated. In contrast, a closing operation results in small gaps being retained or filled up (see closing).

opening serves to eliminate small regions (smaller than StructElement) and to smooth the boundaries of a region. The position of StructElement is meaningless, since an opening operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- **Region** (input_object) region(-array) ~ object
  Regions to be opened.
- **StructElement** (input_object) region ~ object
  Structuring element (position-invariant).
- **RegionOpening** (output_object) region(-array) ~ object
  Opened regions.

Example

* Large regions in an aerial picture (beech trees or meadows):
  read_image(Image,'forest_road')
  threshold(Image,Light,160,255)
  gen_circle(StructElement,100,100,10)
  * selecting the large regions
  opening(Light,StructElement,Large)
  * Selecting of edges with certain orientation:
  read_image(Image,'fabrik')
  sobel_amp(Image,Sobel,'sum_abs',3)
  threshold(Sobel,Edges,10,255)
  gen_rectangle2(StructElement,100,100,3.07819,20,1)
  opening(Edges,StructElement,Direction)

Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F_1} \cdot \sqrt{F_2}) .$$

Result

opening returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:
• no region:
  `set_system('no_object_result',<RegionResult>)`
• empty region:
  `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

---

**Parallelization**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

---

**Possible Predecessors**

`threshold`, `regiongrowing`, `connection`, `union1`, `watersheds`, `class_ndim_norm`, `gen_circle`, `gen_ellipse`, `gen_rectangle1`, `gen_rectangle2`, `draw_region`, `gen_region_points`, `gen_region_polygon_filled`

---

**See also**

`gen_circle`, `gen_rectangle2`, `gen_region_polygon`

---

**Module**

---

### `opening_circle` (Region : RegionOpening : Radius : )

**Open a region with a circular structuring element.**

`opening_circle` is defined as an erosion followed by a Minkowski addition with a circular structuring element (see example). `opening` serves to eliminate small regions (smaller than the circular structuring element) and to smooth the boundaries of a region.

---

**Parameters**

- **Region** (input_object)  
  region(-array)  \(\sim\)  object  
  Regions to be opened.
- **RegionOpening** (output_object)  
  region(-array)  \(\sim\)  object  
  Opened regions.
- **Radius** (input_control)  
  real  \(\sim\)  real / integer  
  Radius of the circular structuring element.

**Default value:** 3.5

**Suggested values:**  
Radius \(\in\) \{1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5\}

**Typical range of values:**  
0.5 \(\leq\) Radius \(\leq\) 511.5 (lin)

**Minimum increment:** 1.0

**Recommended increment:** 1.0

---

**Example**

* Large regions in an aerial picture (beech trees or meadows):
  `read_image (Image, 'forest_road')`
  `threshold (Image, Region, 120, 255)`
* Close the small gaps.
  `closing_circle (Region, RegionClosing, 3.5)`
* Select the large regions.
  `opening_circle (RegionClosing, RegionOpening, 19.5)`
Complexity

Let $F_1$ be the area of the input region. Then the runtime complexity for one region is:

$$O(4 \cdot \sqrt{F_1} \cdot \text{Radius}) .$$

Result

opening_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

opening, dilation1, minkowski_add1, gen_circle

transpose_region

Module

opening_rectangle1 ( Region : RegionOpening : Width, Height : )

Open a region with a rectangular structuring element.

opening_rectangle1 performs an erosion_rectangle1 followed by a dilation_rectangle1 on the input region Region. The size of the rectangular structuring element is determined by the parameters Width and Height. As is the case for all opening variants, larger structures are preserved, while small regions like lines or points are eliminated.

Parameters

- **Region** (input_object) ................................. region(-array) $\rightsquigarrow$ object
  Regions to be opened.
- **RegionOpening** (output_object) .............................. region(-array) $\rightsquigarrow$ object
  Opened regions.
- **Width** (input_control) .............................. extent.x $\rightsquigarrow$ integer
  Width of the structuring rectangle.

Default value: 10

Suggested values: Width ∈ {1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200}

Typical range of values: 1 ≤ Width ≤ 511 (lin)

Minimum increment: 1

Recommended increment: 1

20.2. REGION

▷ **Height** (input_control) ................................................................. extent.y ~ integer

- Height of the structuring rectangle.
- **Default value:** 10
- **Suggested values:** Height ∈ \{1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200\}
- **Typical range of values:** \(1 \leq \text{Height} \leq 511\) (lin)
- **Minimum increment:** 1
- **Recommended increment:** 1

**Complexity**

Let \(F_1\) be the area of an input region and \(H\) be the height of the rectangle. Then the runtime complexity for one region is:

\[
O(2 \cdot \sqrt{F_1} \cdot \log(H))
\]

**Result**

`opening_rectangle1` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:**
  ```
  set_system(‘no_object_result’,<RegionResult>)
  ```
- **empty region:**
  ```
  set_system(‘empty_region_result’,<RegionResult>)
  ```

Otherwise, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Predecessors**

threshold, regiongrowing, watersheds, class_ndim_norm

**Possible Successors**

reduce_domain, select_shape, area_center, connection

**Alternatives**

opening, gen_rectangle1, dilation_rectangle1, erosion_rectangle1

**Foundation**

```
pruning ( Region : RegionPrune : Length : )
```

*Prune the branches of a region.*

`pruning` removes branches from a skeleton (`Region`) having a length less than `Length`. All other branches are preserved.

**Parameters**

▷ **Region** (input_object) ................................................................. region-array ~ object
- Regions to be processed.
▷ **RegionPrune** (output_object) ...................................................... region-array ~ object
- Result of the pruning operation.
▷ **Length** (input_control) ............................................................... integer ~ integer
- Length of the branches to be removed.
- **Default value:** 2
- **Suggested values:** `Length` ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
- **Typical range of values:** \(1 \leq \text{Length} \leq 511\) (lin)
- **Minimum increment:** 1
- **Recommended increment:** 1
Complexity

Let $F$ be the area of the input region. Then the runtime complexity for one region is

$$O(\text{Length} \cdot 3 \cdot \sqrt{F}).$$

Result

pruning returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

- skeleton

Possible Successors

- reduce_domain, select_shape, area_center, connection
- junctions_skeleton

See also

- Foundation

Module

**top_hat** ( Region, StructElement : RegionTopHat : : )

Compute the top hat of regions.

top_hat computes the opening of Region with StructElement. The difference between the original region and the result of the opening is called the top hat. In contrast to opening, which splits regions under certain circumstances, top_hat computes the regions removed by such a splitting.

The position of StructElement is meaningless, since an opening operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- **Region** (input_object) ........................................... region(-array) $\rightarrow$ object
  Regions to be processed.
- **StructElement** (input_object) ........................................... region $\rightarrow$ object
  Structuring element (position independent).
- **RegionTopHat** (output_object) ........................................... region(-array) $\rightarrow$ object
  Result of the top hat operator.

Result

top_hat returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:
20.2. REGION

- no region:
  \[ \text{set_system('no_object_result',<RegionResult>)} \]
- empty region:
  \[ \text{set_system('empty_region_result',<RegionResult>)} \]

Otherwise, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Chapter 21

OCR

21.1 Convolutional Neural Networks

clear_ocr_class_cnn ( : : OCRHandle : )

Clear an CNN-based OCR classifier.
clear_ocr_class_cnn clears the OCR classifier given by OCRHandle that was read with read_ocr_class_cnn and frees all memory required for the classifier. After calling clear_ocr_class_cnn, the classifier can no longer be used. The handle OCRHandle becomes invalid.

Parameters

⊿ OCRHandle (input_control) .......................... ocr_cnn(-array) ~ handle
Handle of the OCR classifier.

Result

If OCRHandle is valid, the operator clear_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
do_ocr_single_class_cnn, do_ocr_multi_class_cnn, do_ocr_word_cnn

See also

read_ocr_class_cnn

Module

OCR/OCV

deserialize_ocr_class_cnn ( : : SerializedItemHandle : OCRHandle )

Deserialize a serialized CNN-based OCR classifier.
deserialize_ocr_class_cnn deserializes a CNN-based OCR classifier, that was serialized by serialize_ocr_class_cnn (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

Parameters

- **SerializedItemHandle** (input_control) .......................... serialized_item ~ handle Handle of the serialized item.
- **OCRHandle** (output_control) .......................... ocr_cnn ~ handle Handle of the OCR classifier.

Result

If the parameters are valid, the operator deserialize_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_ocr_class_cnn

Possible Successors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn

Module

OCR/OCV

do_ocr_multi_class_cnn ( Character, Image : : OCRHandle : Class, Confidence )

Classify multiple characters with an CNN-based OCR classifier.

do_ocr_multi_class_cnn computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence.

In contrast to do_ocr_single_class_cnn, do_ocr_multi_class_cnn can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_cnn to classify single characters. However, do_ocr_multi_class_cnn can only return the best class of each character. Because the confidences can be interpreted as probabilities, it is easier to check whether a character has been classified with too much uncertainty. This is usually not a disadvantage, except in cases where the classes overlap so much that in many cases the second best class must be examined to be able to decide the class of the character. In these cases, do_ocr_single_class_cnn should be used.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Parameters

- **Character** (input_object) .................................. region(-array) ~ object Characters to be recognized.
- **Image** (input_object) .................................. singlechannelimage ~ object : byte / uint2 Gray values of the characters.
- **OCRHandle** (input_control) .................................. ocr_cnn ~ handle Handle of the OCR classifier.
- **Class** (output_control) .................................. string(-array) ~ string Result of classifying the characters with the CNN.

Number of elements: Class == Character
21.1. CONVOLUTIONAL NEURAL NETWORKS

Confidence (output_control)  
Confidence of the class of the characters.
Number of elements: Confidence == Character

If the parameters are valid, the operator do_ocr_multi_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

read_ocr_class_cnn

Alternatives

do_ocr_word_cnn, do_ocr_single_class_cnn

Module

OCR/OCV

do_ocr_single_class_cnn ( Character, Image : : OCRHandle,
Num : Class, Confidence )

Classify a single character with an CNN-based OCR classifier.

do_ocr_single_class_cnn computes the best classification for the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the best Num classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Because multiple classes may be returned by do_ocr_single_class_cnn, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_cnn must be used.

In most cases, do_ocr_multi_class_cnn should be preferred over do_ocr_single_class_cnn, since do_ocr_multi_class_cnn is typically faster than a loop with do_ocr_single_class_cnn. Furthermore, the resulting confidences can be interpreted as probabilities. They indicate the uncertainty of a character’s classification result. The operator do_ocr_single_class_cnn has to be used if the nth-best class has to be examined explicitly for n greater than one.

A string of the number ‘\032’ (alternatively displayed as ‘\0r1A’) in Class signifies that the region has been classified as rejection class.

Parameters

- Character (input_object)  
Character to be recognized.
- Image (input_object)  
Gray values of the character.
- OCRHandle (input_control)  
Handle of the OCR classifier.
- Num (input_control)  
Number of best classes to determine.
  Default value: 1
  Suggested values: Num ∈ {1, 2, 3, 4, 5}
- Class (output_control)  
Result of classifying the character with the CNN.
- Confidence (output_control)  
Confidence(s) of the class(es) of the character.
Example

read_image(Image, 'bottle2')
OffsetRow := 100
OffsetCol := 108
read_ocr_class_cnn('Universal_0-9_NoRej.occ', OCRHandle)
* Select each digit and use do_ocr_single_class_cnn to apply OCR
gen_rectangle1(ROI_Date, OffsetRow, OffsetCol, OffsetRow, OffsetCol)
for I := 1 to 6 by 1
   Offset := I % 2 * 10
   smallest_rectangle1(ROI_Date, Row1, Col1, Row2, Col2)
   gen_rectangle1(ROI_Date, OffsetRow, Offset + Col2, OffsetRow + 42, \
     Col2 + Offset + 31)
   do_ocr_single_class_cnn(ROI_Date, Image, OCRHandle, 1, Class, Confidence)
endfor

Result
If the parameters are valid, the operator do_ocr_single_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

Possible Predecessors

read_ocr_class_cnn

Alternatives

do_ocr_multi_class_cnn

Module

OCR/OCV

\textbf{do_ocr_word_cnn} ( Character, Image : : OCRHandle, Expression, 
   NumAlternatives, NumCorrections : Class, Confidence, Word, 
   Score )

\textit{Classify a related group of characters with an CNN-based OCR classifier.}

do_ocr_word_cnn works like \textbf{do_ocr_multi_class_cnn} insofar as it computes the best class for each of 
the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, 
and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. 
In contrast to do_ocr_multi_class_cnn, do_ocr_word_cnn treats the group of characters as an entity 
which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed 
classification results on a textual level by specifying an Expression describing the expected word. 
The Expression may restrict the word to belong to a predefined lexicon created using \texttt{create_lexicon} or 
import_lexicon, or by specifying the name of the lexicon in angular brackets as in '\texttt{<mylexicon>}' . If the Expression 
is of any other form, it is interpreted as a regular expression with the same syntax as specified for 
tuple_regexp_match. Note that you will usually want to use an expression of the form '\texttt{^...$}' when using 
variable quantifiers like '\texttt{*}' , to ensure that the entire word is used in the expression. Also note that in contrast to 
tuple_regexp_match, do_ocr_word_cnn does not support passing extra options in an expression tuple. 
If the word derived from the best class for each character does not match the Expression, do_ocr_word_cnn 
 attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives 
used are identical to those returned by do_ocr_single_class_cnn for a single character. It does so by testing 
all possible corrections for which the classification result is changed for at most NumCorrections character
21.1. CONVOLUTIONAL NEURAL NETWORKS

regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

\[
Score = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\text{PenaltyCorrections} = \alpha \times \text{num_corr}
\]

\[
\text{PenaltyAlternatives} = \alpha \times \beta \times \text{num_alt}
\]

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

\[
\alpha = \frac{1}{\text{NumCorrections} + 1}
\]

\[
\beta = \frac{1}{\text{NumCorrections} \times (\text{NumAlternatives} - 1) + 2}
\]

Note that this is a combinatorial score which does not reflect the original Confidence of the best Class.

A string of the number ‘\(0x1A\)’ (alternatively displayed as ‘\(0x1A\)’) in Class signifies that the region has been classified as rejection class.

---

Parameters

- **Character** (input_object) ............................................. region(-array) \sim object
  Characters to be recognized.

- **Image** (input_object) ............................................. singlechannelimage \sim object : byte / uint2
  Gray values of the characters.

- **OCRHandle** (input_control) ........................................... ocr_cnn \sim handle
  Handle of the OCR classifier.

- **Expression** (input_control) ........................................... string \sim string
  Expression describing the allowed word structure.

- **NumAlternatives** (input_control) ...................................... integer \sim integer
  Number of classes per character considered for the internal word correction.

  **Default value:** 3
  **Suggested values:** NumAlternatives \in \{3, 4, 5\}
  **Typical range of values:** 1 \leq \text{NumAlternatives}

- **NumCorrections** (input_control) ...................................... integer \sim integer
  Maximum number of corrected characters.

  **Default value:** 2
  **Suggested values:** NumCorrections \in \{1, 2, 3, 4, 5\}
  **Typical range of values:** 0 \leq \text{NumCorrections}

- **Class** (output_control) ............................................. string(-array) \sim string
  Result of classifying the characters with the CNN.
  **Number of elements:** Class == Character

- **Confidence** (output_control) ........................................... real(-array) \sim real
  Confidence of the class of the characters.
  **Number of elements:** Confidence == Character

- **Word** (output_control) ............................................. string \sim string
  Word text after classification and correction.
The complexity of checking all possible corrections is of magnitude $O((n \times a)\min(n,c))$, where $a$ is the number of alternatives, $n$ is the number of character regions, and $c$ is the number of allowed corrections. However, to guard against a near-infinite loop in case of large $n$, $c$ is internally clipped to 5, 3, or 1 if $a \times n \geq 30$, 60, or 90, respectively.

If the parameters are valid, the operator `do_ocr_word_cnn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

read_ocr_class_cnn

Possible Successors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn

Module

query_params_ocr_class_cnn ( : : OCRHandle : GenParamName )

Get the names of the parameters that can be used in get_params_ocr_class_cnn for a given CNN-based OCR classifier.

The operator query_params_ocr_class_cnn returns the parameter names that can be used to query all parameters for a given CNN-based OCR classifier. The resulting parameter names can be used as input parameter when calling get_params_ocr_class_cnn.

Parameters

- **OCRHandle** (input_control) .......................................................... ocr_cnn → handle
  Handle of OCR classifier.
- **GenParamName** (output_control) ............................................. string(-array) → string
  Names of the generic parameters.

Result

The operator query_params_ocr_class_cnn returns the value 2 (H_MSG_TRUE) if the given handle for the OCR classifier is correct. Otherwise, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors

get_params_ocr_class_cnn

Module

read_ocr_class_cnn ( : : FileName : OCRHandle )

Read an CNN-based OCR classifier from a file.

read_ocr_class_cnn reads a pretrained OCR classifier based on a convolutional neural network (CNN).

The CNN-based OCR classifier is read with read_ocr_class_cnn and subsequently used for classification with either do_ocr_single_class_cnn, do_ocr_multi_class_cnn, or do_ocr_word_cnn.

HALCON provides a number of pretrained OCR classifiers (see "Solution Guide I", chapter 'OCR', section 'Pretrained OCR Fonts'). These pretrained OCR classifiers make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Note that the pretrained OCR classifiers were trained with symbols that are printed dark on light.

HALCON 20.05.0.0
Parameters

- **FileName** (input_control) .......................................................... filename.read \(\sim\) string
  
  File name.
  
  **Default value:** 'Universal_Rej.occ'
  
  
  **File extension:** .occ, .fnt

- **OCRHandle** (output_control) .................................................. ocr_cnn \(\sim\) handle
  
  Handle of the OCR classifier.

If the parameters are valid, the operator `read_ocr_class_cnn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

- do_ocr_single_class_cnn, do_ocr_multi_class_cnn, do_ocr_word_cnn

See also

- `get_params_ocr_class_cnn`

Module

- OCR/OCV

```
serialize_ocr_class_cnn ( : : OCRHandle : SerializedItemHandle )
```

Serializes a CNN-based OCR classifier

`serialize_ocr_class_cnn` serializes a CNN-based OCR classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The OCR classifier is defined by the handle `OCRHandle`. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr_class_cnn`.

Parameters

- **OCRHandle** (input_control) .................................................. ocr_cnn \(\sim\) handle
  
  Handle of the OCR classifier.

- **SerializedItemHandle** (output_control) ................................. serialized_item \(\sim\) handle
  
  Handle of the serialized item.

If the parameters are valid, the operator `serialize_ocr_class_cnn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
21.2 K-Nearest Neighbors

**clear_ocr_class_knn** ( : : OCRHandle : )

Clear an OCR classifier.

**clear_ocr_class_knn** clears the OCR classifier given by **OCRHandle** that was created with **create_ocr_class_knn** and frees all memory required for the classifier. After calling **clear_ocr_class_knn**, the classifier can no longer be used. The handle **OCRHandle** becomes invalid.

**Parameters**

- **OCRHandle** (input_control) Handle of the OCR classifier.

**Result**

If **OCRHandle** is valid, the operator **clear_ocr_class_knn** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **OCRHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Successors**

clear_ocr_class_cnn, fwrite_serialized_item, send_serialized_item, deserialize_ocr_class_cnn

Possible Predecessors

trainf_ocr_class_knn, read_ocr_class_knn

See also

create_class_knn

**References**

**Create an OCR classifier using a k-Nearest Neighbor (k-NN) classifier.**

**create_ocr_class_knn** creates an OCR classifier that uses a k-Nearest Neighbor (k-NN). The handle of the k-NN classifier is returned in **OCRHandle**.

For a description on how a k-NN works, see **create_class_knn**.

**HALCON 20.05.0.0**
The length of the feature vector of the k-NN is determined from the features that are used for the OCR, which are passed in **Features**. The features are described below. The number of classes is determined from the names of the characters which are passed in **Characters**.

**Features** can contain a tuple of several feature names. Each of these names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., **'pixel_invar'**). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by **WidthCharacter** and **HeightCharacter**. The interpolation to be used for the transformation is determined by **Interpolation**. It has the same meaning as in **affine_trans_image**. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, **Interpolation = 'constant'** should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, large sizes will cause small segmentation errors to have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, which results in characters are zoomed differently than the characters in the training set. In most applications, sizes between $6 \times 8$ and $10 \times 14$ should be used.

The parameter **Features** can contain the following feature names for the classification of the characters.

- **'default'**:  'ratio' and **'pixel_invar'** are selected.
- **'pixel'**: Gray values of the character ($\text{WidthCharacter} \times \text{HeightCharacter}$ features).
- **'pixel_invar'**: Gray values of the character with maximum scaling of the gray values ($\text{WidthCharacter} \times \text{HeightCharacter}$ features).
- **'pixel_binary'**: Region of the character as a binary image zoomed to a size of $\text{WidthCharacter} \times \text{HeightCharacter}$ ($\text{WidthCharacter} \times \text{HeightCharacter}$ features).
- **'gradient_8dir'**: Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a $5 \times 5$ grid are extracted from each channel. These samples are used as features (200 features).
- **'projection_horizontal'**: Horizontal projection of the gray values (see **gray_projections**, **HeightCharacter** features).
- **'projection_horizontal_invar'**: Maximally scaled horizontal projection of the gray values ($\text{HeightCharacter}$ features).
- **'projection_vertical'**: Vertical projection of the gray values (see **gray_projections**, **WidthCharacter** features).
- **'projection_vertical_invar'**: Maximally scaled vertical projection of the gray values ($\text{WidthCharacter}$ features).
- **'ratio'**: Aspect ratio of the character (see **height_width_ratio**, 1 feature).
- **'anisometry'**: Anisometry of the character (see **eccentricity**, 1 feature).
- **'width'**: Width of the character before scaling the character to the standard size (not scale-invariant, see **height_width_ratio**, 1 feature).
- **'height'**: Height of the character before scaling the character to the standard size (not scale-invariant, see **height_width_ratio**, 1 feature).
- **'zoom_factor'**: Difference in size between the character and the values **WidthCharacter** and **HeightCharacter** (not scale-invariant, 1 feature).
- **'foreground'**: Fraction of pixels in the foreground (1 feature).
- **'foreground_grid_9'**: Fraction of pixels in the foreground in a $3 \times 3$ grid within the smallest enclosing rectangle of the character (9 features).
- **'foreground_grid_16'**: Fraction of pixels in the foreground in a $4 \times 4$ grid within the smallest enclosing rectangle of the character (16 features).
- **'compactness'**: Compactness of the character (see **compactness**, 1 feature).
- **'convexity'**: Convexity of the character (see **convexity**, 1 feature).
- **'moments_region_2nd_invar'**: Normalized 2nd moments of the character (see **moments_region_2nd_invar**, 3 features).
- **'moments_region_2nd_rel_invar'**: Normalized 2nd relative moments of the character (see **moments_region_2nd_rel_invar**, 2 features).
21.2. K-NEAREST NEIGHBORS

'\texttt{moments\_region\_3rd\_invar}:' Normalized 3rd moments of the character (see \texttt{moments\_region\_3rd\_invar}, 4 features).

'\texttt{moments\_central}:' Normalized central moments of the character (see \texttt{moments\_region\_central}, 4 features).

'\texttt{moments\_gray\_plane}:' Normalized gray value moments and the angle of the gray value plane (see \texttt{moments\_gray\_plane}, 4 features).

'\texttt{phi}:' Sinus and cosinus of the orientation (angle) of the character (see \texttt{elliptic\_axis}, 2 feature).

'\texttt{num\_connect}:' Number of connected components (see \texttt{connect\_and\_holes}, 1 feature).

'\texttt{num\_holes}:' Number of holes (see \texttt{connect\_and\_holes}, 1 feature).

'\texttt{cooc}:' Values of the binary cooccurrence matrix (see \texttt{gen\_cooc\_matrix}, 8 features).

'\texttt{num\_runs}:' Number of runs in the region normalized by the height (1 feature).

'\texttt{chord\_histo}:' Frequency of the runs per row (not scale-invariant, \texttt{HeightCharacter} features).

After the classifier has been created, it is trained using \texttt{trainf\_ocr\_class\_knn}. After this, the classifier can be saved using \texttt{write\_ocr\_class\_knn}. Alternatively, the classifier can be used immediately after training to classify characters using \texttt{do\_ocr\_single\_class\_knn} or \texttt{do\_ocr\_multi\_class\_knn}.

A comparison of the k-NN and the support vector machine (SVM) (see \texttt{create\_ocr\_class\_svm}) typically shows that SVMs are generally slower at training, especially for huge training sets, but achieve slightly better recognition rates than k-NNs. Please note that this guideline assumes optimal tuning of the parameters of the SVM.

---

**Parameters**

- **WidthCharacter** (input_control) ......................................................... integer $\sim$ integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 8
  Suggested values: $\text{WidthCharacter} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20\}$
  Typical range of values: $4 \leq \text{WidthCharacter} \leq 20$

- **HeightCharacter** (input_control) ......................................................... integer $\sim$ integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 10
  Suggested values: $\text{HeightCharacter} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20\}$
  Typical range of values: $4 \leq \text{HeightCharacter} \leq 20$

- **Interpolation** (input_control) ............................................................. string $\sim$ string
  Interpolation mode for the zooming of the characters.
  Default value: 'constant'
  List of values: \{'nearest\_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'\}

- **Features** (input_control) ................................................................. string(-array) $\sim$ string
  Features to be used for classification.
  Default value: 'default'
  List of values: \{'default', 'pixel', 'pixel\_invar', 'pixel\_binary', 'gradient\_8dir',
  'projection\_horizontal', 'projection\_horizontal\_invar', 'projection\_vertical', 'projection\_vertical\_invar',
  'ratio', 'anisometry', 'width', 'height', 'zoom\_factor', 'foreground', 'foreground\_grid\_9',
  'foreground\_grid\_16', 'compactness', 'convexity', 'moments\_region\_2nd\_invar',
  'moments\_region\_2nd\_rel\_invar', 'moments\_region\_3rd\_invar', 'moments\_central', 'moments\_gray\_plane',
  'phi', 'num\_connect', 'num\_holes', 'cooc', 'num\_runs', 'chord\_histo'\}

- **Characters** (input_control) .............................................................. string-array $\sim$ string
  All characters of the character set to be read.
  Default value: ['0', '1', '2', '3', '4', '5', '6', '7', '8', '9']

- **GenParamName** (input_control) ...................................................... string-array $\sim$ string
  This parameter is not yet supported.
  Default value: []
  List of values: \{\}[

- **GenParamValue** (input_control) ...................................................... number-array $\sim$ integer / string
  This parameter is not yet supported.
  Default value: []
  List of values: \{\}[

- **OCRHandle** (output_control) .......................................................... ocr\_knn $\sim$ handle
  Handle of the k-NN classifier.
Example

read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image, &Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
    Classes := [Classes, gen_tuple_const(20, chr(ord('a')+J))]
endfor
Classes := [Classes, gen_tuple_const(20, '.')]
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_knn (8, 10, 'constant', 'default', CharacterNames, [], [], OCRHandle)
trainf_ocr_class_knn (OCRHandle, 'letters.trf', [], [])
* Re-classify the characters in the image.
do_ocr_multi_class_knn (Characters, Image, OCRHandle, Class, Confidence)

Result

If the parameters are valid, the operator create_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

trainf_ocr_class_knn

Alternatives

create_ocr_class_svm

Module

OCR/OCV

deserialize_ocr_class_knn ( : : SerializedItemHandle : OCRHandle )

Deserialize a serialized k-NN-based OCR classifier.
deserialize_ocr_class_knn deserializes a k-NN-based OCR classifier, that was serialized by serialize_ocr_class_knn (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.
21.2. K-NEAREST NEIGHBORS

Parameters

- **SerializedItemHandle** (input_control) 
  Handle of the serialized item.

- **OCRHandle** (output_control) 
  Handle of the OCR classifier.

Result

If the parameters are valid, the operator **deserialize_ocr_class_knn** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

**OCR/OCV**

do_ocr_multi_class_knn ( Character, Image : : OCRHandle : Class, Confidence )

Classify multiple characters with an k-NN classifier.

do_ocr_multi_class_knn computes the best class for each of the characters given by the regions **Character** and the gray values **Image** with the k-NN classifier **OCRHandle** and returns the classes in **Class** and the corresponding confidence of the classes in **Confidence**. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification of the single characters. In contrast to **do_ocr_single_class_knn**, **do_ocr_multi_class_knn** can classify multiple characters in one call, and therefore typically is faster than a loop that uses **do_ocr_single_class_knn** to classify single characters. However, **do_ocr_multi_class_knn** can only return the best class of each character.

Before calling **do_ocr_multi_class_knn**, the classifier must be trained with **trainf_ocr_class_knn**.

Parameters

- **Character** (input_object) 
  Characters to be recognized.

- **Image** (input_object) 
  Gray values of the characters.

- **OCRHandle** (input_control) 
  Handle of the k-NN classifier.

- **Class** (output_control) 
  Result of classifying the characters with the k-NN.

  Number of elements: Class == array

- **Confidence** (output_control) 
  Confidence of the class of the characters.

  Number of elements: Confidence == array
If the parameters are valid, the operator `do_ocr_multi_class_knn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

- **Parallelization**
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Automatically parallelized on tuple level.

- **Possible Predecessors**
  - `trainf_ocr_class_knn`, `read_ocr_class_knn`

- **Alternatives**
  - `do_ocr_single_class_knn`

- **See also**
  - `create_ocr_class_knn`, `classify_class_knn`

- **Module**
  - OCR/OCV

```c
do_ocr_single_class_knn ( Character, Image : : OCRHandle,
                             NumClasses, NumNeighbors : Class, Confidence )
```

**Classify a single character with an OCR classifier.**

`do_ocr_single_class_knn` uses the OCR-k-NN classifier `OCRHandle` to determine the best training samples for the features of the character given by the region `Character` and the gray values `Image` and returns their classes in `Class` and the corresponding confidences in `Confidence`. If the first `NumNeighbors` training vectors have different classes, maximally `NumClasses` classes are returned sorted by frequency and weighted distance. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification. The confidence can be only computed robustly if `NumNeighbors` is large enough.

Because multiple classes may be returned by `do_ocr_single_class_knn`, `Character` may only contain a single region (a single character). If multiple characters should be classified in a single call, `do_ocr_multi_class_knn` must be used. Before calling `do_ocr_single_class_knn`, the classifier must be trained with `trainf_ocr_class_knn` or `select_feature_set_trainf_knn`. If all `NumNeighbors` neighbors are of the same class, only one class is returned.

- **Parameters**
  - `Character` (input_object) .......................... region  \( \sim \) object
    Character to be recognized.
  - `Image` (input_object) ......................... singlechannelimage  \( \sim \) object : byte / uint2
    Gray values of the character.
  - `OCRHandle` (input_control) .................. ocr_knn  \( \sim \) handle
    Handle of the k-NN classifier.
  - `NumClasses` (input_control) ................ integer-array  \( \sim \) integer
    Number of maximal classes to determine.
    **Default value:** 1
    **Suggested values:** `NumClasses` \( \in \{1, 2, 3, 4, 5\}`
  - `NumNeighbors` (input_control) .............. integer-array  \( \sim \) integer
    Number of neighbors to consider.
    **Default value:** 1
    **Suggested values:** `NumNeighbors` \( \in \{1, 2, 3, 4, 5\}`
  - `Class` (output_control) ......................... string(-array)  \( \sim \) string
    Results of classifying the character with the k-NN.
  - `Confidence` (output_control) ................. real(-array)  \( \sim \) real
    Confidence(s) of the class(es) of the character.
21.2. K-NEAREST NEIGHBORS

Result
If the parameters are valid, the operator do_ocr_single_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

create_ocr_class_knn, classify_class_knn
Module
OCR/OCV

do_ocr_word_knn ( Character, Image : : OCRHandle, Expression,
NumAlternatives, NumCorrections : Class, Confidence, Word,
Score )

Classify a related group of characters with an OCR classifier.

do_ocr_word_knn works like do_ocr_multi_class_knn insofar as it computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, and returns the classes in Class and the corresponding confidences of the classes in Confidence. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification of the single characters.

In contrast to do_ocr_multi_class_knn, do_ocr_word_knn treats the group of characters as an entity which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or import_lexicon, by specifying the name of the lexicon in angular brackets as in `<mylexicon>`. If the Expression is of any other form, it is interpreted as a regular expression with the same syntax as specified for tuple_regexp_match. Note that you will usually want to use an expression of the form `'^...$'` when using variable quantifiers like `'*'`, to ensure that the entire word is used in the expression. Also note that in contrast to tuple_regexp_match, do_ocr_word_knn does not support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_knn attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives used are identical to those returned by do_ocr_single_class_knn for a single character. It does so by testing all possible corrections for which the classification result is changed for at most NumCorrections character regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

\[
\text{Score} = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\text{PenaltyCorrections} = \alpha \cdot \text{num_corr}
\]

\[
\text{PenaltyAlternatives} = \alpha \cdot \beta \cdot \text{num_alt}
\]
with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

\[ \alpha = \frac{1}{\text{NumCorrections} + 1} \]
\[ \beta = \frac{1}{\text{NumCorrections} \ast (\text{NumAlternatives} - 1) + 2} \]

Note that this is a combinatorial score which does not reflect the original Confidence of the best Class.

---

**Parameters**

- **Character** (input_object) ... region(-array) \( \sim \) object
  Characters to be recognized.
- **Image** (input_object) ... singlechannelimage \( \sim \) object : byte / uint2
  Gray values of the characters.
- **OCRHandle** (input_control) ... ocr_knn \( \sim \) handle
  Handle of the OCR classifier.
- **Expression** (input_control) ... string \( \sim \) string
  Expression describing the allowed word structure.
- **NumAlternatives** (input_control) ... integer \( \sim \) integer
  Number of classes per character considered for the internal word correction.
  Default value: 3
  Suggested values: NumAlternatives \( \in \{3, 4, 5\} \)
  Typical range of values: \( 1 \leq \text{NumAlternatives} \leq 5 \)
- **NumCorrections** (input_control) ... integer \( \sim \) integer
  Maximum number of corrected characters.
  Default value: 2
  Suggested values: NumCorrections \( \in \{1, 2, 3, 4, 5\} \)
  Typical range of values: \( 0 \leq \text{NumCorrections} \leq 5 \)
- **Class** (output_control) ... string(-array) \( \sim \) string
  Result of classifying the characters with the k-NN.
  Number of elements: Class \( \equiv \) Character
- **Confidence** (output_control) ... real(-array) \( \sim \) real
  Confidence of the class of the characters.
  Number of elements: Confidence \( \equiv \) Character
- **Word** (output_control) ... string \( \sim \) string
  Word text after classification and correction.
- **Score** (output_control) ... real \( \sim \) real
  Measure of similarity between corrected word and uncorrected classification results.

---

**Complexity**

The complexity of checking all possible corrections is of magnitude \( O((n \ast a)^{\min(c,n)}) \), where \( a \) is the number of alternatives, \( n \) is the number of character regions, and \( c \) is the number of allowed corrections. However, to guard against a near-infinite loop in case of large \( n \), \( c \) is internally clipped to 5, 3, or 1 if \( a \ast n \geq 30, 60, \) or 90, respectively.

---

**Result**

If the parameters are valid, the operator do_ocr_word_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

Module

OCR/OCV

get_features_ocr_class_knn ( Character : : OCRHandle,
Transform : : Features )

Compute the features of a character.

get_features_ocr_class_knn computes the features of the character given by Character with the k-NN classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_knn and do_ocr_multi_class_knn, the character is passed as a single image object. Hence, before calling get_features_ocr_class_knn, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_knn for the classifier should be applied (Transform = 'true') or whether the untransformed features should be returned (Transform = 'false'). get_features_ocr_class_knn can be used to inspect the features that are used for the classification.

Parameters

Characters (input_object) .................................................. singlechannelimage ~ object : byte / uint2
Input character.

OCRHandle (input_control) .............................................. ocr_knn ~ handle
Handle of the k-NN classifier.

Transform (input_control) .............................................. string ~ string
Should the feature vector be transformed with the preprocessing?
Default value: 'true'
List of values: Transform ∈ ['true', 'false']

Features (output_control) .............................................. real-array ~ real
Feature vector of the character.

Result

If the parameters are valid, the operator get_features_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

OCR/OCV

get_params_ocr_class_knn ( : : OCRHandle : WidthCharacter,
HeightCharacter, Interpolation, Features, Characters,
Preprocessing, NumTrees )

Return the parameters of an OCR classifier.

HALCON 20.05.0.0
get_params_ocr_class_knn returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_knn. This is particularly useful if the classifier was read with read_ocr_class_knn. The output of get_params_ocr_class_knn can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_knn and trainf_ocr_class_knn.

### Parameters

- **OCRHandle** (input_control)  
  Handle of the OCR classifier.
- **WidthCharacter** (output_control)  
  Width of the rectangle to which the gray values of the segmented character are zoomed.
- **HeightCharacter** (output_control)  
  Height of the rectangle to which the gray values of the segmented character are zoomed.
- **Interpolation** (output_control)  
  Interpolation mode for the zooming of the characters.
- **Features** (output_control)  
  Features to be used for classification.
- **Characters** (output_control)  
  Characters of the character set to be read.
- **Preprocessing** (output_control)  
  Type of preprocessing used to transform the feature vectors.
- **NumTrees** (output_control)  
  Number of different trees used during the classification.

### Result

If the parameters are valid, the operator get_params_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```

Select an optimal combination of features to classify OCR data.

`select_feature_set_trainf_knn` selects an optimal combination of features, to classify the data given in the training file `TrainingFile` with a k-Nearest Neighbor classifier, for details see `create_ocr_class_knn`.

Possible features are all OCR features listed and explained in `create_ocr_class_knn`. All candidates which should be tested can be specified in `FeatureList`. A subset of these features is returned as selected features in `FeatureSet`.

`select_feature_set_trainf_knn` is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator `select_feature_set_knn`.

The selection method `SelectionMethod` is either a greedy search 'greedy' (iteratively add the feature with highest gain) or the dynamically oscillating search 'greedy_oscillating' (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method 'greedy' is generally preferable, since it is faster. Only in cases when a large training set is available the method 'greedy_oscillating' might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in `Score`.

The k-NN classifier can be parametrized using the following values in `GenParamName` and `GenParamValue`:

'num_neighbors': The number of minimally evaluated nodes, increase this value for high dimensional data.

  - Possible values: '1', '2', '5', '10'
  - Default value: '1'

'num_trees': Number of search trees in the k-NN classifier

  - Possible values: '1', '4', '10'
  - Default Value: '4'

---

HALCON 20.05.0.0
Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_knn may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

- **TrainingFile** (input_control) 
  Names of the training files.
  Default value: "
  File extension: .trf, .otr

- **FeatureList** (input_control)
  List of features that should be considered for selection.
  Default value: 

- **SelectionMethod** (input_control)
  Method to perform the selection.
  Default value: 'greedy'
  **List of values:** SelectionMethod ∈ \{'greedy', 'greedy_oscillating'\}

- **Width** (input_control)
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 15

- **Height** (input_control)
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 16

- **GenParamName** (input_control)
  Names of generic parameters to configure the selection process and the classifier.
  Default value: []
  **List of values:** GenParamName ∈ \{'num_neighbors'\}

- **GenParamValue** (input_control)
  Values of generic parameters to configure the selection process and the classifier.
  Default value: []
  **Suggested values:** GenParamValue ∈ {1, 2, 3}

- **OCRHandle** (output_control)
  Trained OCR-k-NN classifier.

- **FeatureSet** (output_control)
  Selected feature set, contains only entries from FeatureList.

- **Score** (output_control)
  Achieved score using two-fold cross-validation.

Result

If the parameters are valid, the operator select_feature_set_trainf_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
21.2. K-NEAREST NEIGHBORS

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

serialize_ocr_class_knn ( : : OCRHandle : SerializedItemHandle )

Serialize a k-NN-based OCR classifier.

serialize_ocr_class_knn serializes a k-NN-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocr_class_knn is converted to a serialized item. The OCR classifier is defined by the handle OCRHandle. The serialized OCR classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocr_class_knn.

Parameters

- **OCRHandle** (input_control) ocr_knn
  Handle of the OCR classifier.
- **SerializedItemHandle** (output_control) serialized_item
  Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

trainf_ocr_class_knn, read_ocr_class_knn

Possible Successors

OCR/OCV

trainf_ocr_class_knn ( : : OCRHandle, TrainingFile, GenParamName, GenParamValue : )

Trains an k-NN classifier for an OCR task.
trainf_ocr_class_knn trains the k-NN classifier OCRHandle with the training characters stored in the OCR training files given by TrainingFile. The training files must have been created, e.g., using write_ocr_trainf, before calling trainf_ocr_class_knn. Please note that training characters that have no corresponding class in the classifier OCRHandle are discarded.

It is possible to set the number of trees via the parameters GenParamName and GenParamValue by ‘num_trees’. The default value for the number of search trees is 4. A higher number of trees improves the accuracy of the search, but also increases the runtime. Normalization can be activated by setting 'normalization' in GenParamName and ‘true’ in GenParamValue. This will change the stored training data permanently. Therefore, adding data after the training is not possible.

--- Parameters ---

> OCRHandle (input_control) .......................... ocr_knn ↦ handle
   Handle of the k-NN classifier.

> TrainingFile (input_control) ........................ filename.read(-array) ↦ string
   Names of the training files.
   Default value: ‘ocr.trf’
   File extension: .trf, .otr

> GenParamName (input_control) ......................... string-array ↦ string
   Names of the generic parameters that can be adjusted for the k-NN classifier creation.
   Default value: []
   List of values: GenParamName ∈ {'num_trees', 'normalization'}

> GenParamValue (input_control) ........................ number-array ↦ integer / string / real
   Values of the generic parameters that can be adjusted for the k-NN classifier creation.
   Default value: []
   Suggested values: GenParamValue ∈ {4, 5, 'false', 'true'}

--- Example ---

* Train an OCR classifier

read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_knn (8, 10, 'constant', 'default', CharacterNames, [],
    [ ], OCRHandle)
trainf_ocr_class_knn (OCRHandle, 'ocr.trf', [], [])
write_ocr_class_knn (OCRHandle, 'ocr.omc')

--- Result ---

If the parameters are valid, the operator trainf_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

--- Parallelization ---

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

This operator modifies the state of the following input parameter:

  ▪ OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

do_ocr_single_class_knn, do_ocr_multi_class_knn

--- Alternatives ---

read_ocr_class_knn
21.3 LEXICA

**write_ocr_class_knn** ( : : OCRHandle, FileName : )

Write a k-NN classifier for an OCR task to a file.

write_ocr_class_knn writes the k-NN classifier for an OCR task with the OCRHandle to the file given by FileName. If a file extension is not specified in FileName the default extension '.onc' is appended to FileName. write_ocr_class_knn is typically called after the classifier has been trained with trainf_ocr_class_knn. The classifier can be read with read_ocr_class_knn.

**Parameters**

- OCRHandle (input_control) .............................. ocr_knn ~ handle
  Handle of the k-NN classifier for an OCR task.
- FileName (input_control) ................................. filename.write ~ string
  File name.
  **File extension**: .onc

**Result**

If the parameters are valid, the operator write_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

21.3 Lexica

**clear_lexicon** ( : : LexiconHandle : )

Clear a lexicon.

clear_lexicon clears a lexicon and releases its resources.

**Parameters**

- LexiconHandle (input_control) ............................. lexicon ~ handle
  Handle of the lexicon.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
create_lexicon ( : : Name, Words : LexiconHandle )

Create a lexicon from a tuple of words.

create_lexicon creates a new lexicon based on a tuple of Words. By specifying a unique textual Name, you can later refer to the lexicon from syntax expressions like those used, e.g., by do_ocr_word_mlp.

Note that lexicon support in HALCON is currently not aimed at natural languages. Rather, it is intended as a post-processing step in OCR applications that only need to distinguish between a limited set of not more than a few thousand valid words, e.g., country or product names. MVTec itself does not provide any lexica.

**Parameters**

- **Name** (input_control) .................... string ~ string
  Unique name for the new lexicon.
  Default value: 'lex1'
- **Words** (input_control) .................. string-array ~ string
  Word list for the new lexicon.
  Default value: ['word1','word2','word3']
- **LexiconHandle** (output_control) ........ lexicon ~ handle
  Handle of the lexicon.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Successors**
do_ocr_word_mlp, do_ocr_word_svm

**Alternatives**
import_lexicon

**See also**
lookup_lexicon, suggest_lexicon

**Module**
OCR/OCV

import_lexicon ( : : Name, FileName : LexiconHandle )

Create a lexicon from a text file.
import_lexicon creates a new lexicon based on a list of words in the file specified by FileName. The format of the file is a simple text file with one word per line. By specifying a unique textual Name, you can later refer to the lexicon from syntax expressions like those used, e.g., by do_ocr_word_mlp.

Note that lexicon support in HALCON is currently not aimed at natural languages. Rather, it is intended as a post-processing step in OCR applications that only need to distinguish between a limited set of not more than a few thousand valid words, e.g., country or product names. When the lexicon file contains entries with special, non-ASCII characters, it is expected to be encoded in UTF-8. However, old lexicon files which use the local 8-bit encoding, can still be loaded as long as they contain at least one byte sequence, which cannot be misinterpreted as UTF-8 character. MVTec itself does not provide any lexica.

Parameters

- **Name** (input_control) string ~> string
  Unique name for the new lexicon.
  Default value: ‘lex1’

- **FileName** (input_control) filename.read ~> string
  Name of a text file containing words for the new lexicon.
  Default value: ‘words.txt’
  File extension: .txt

- **LexiconHandle** (output_control) lexicon ~> handle
  Handle of the lexicon.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

- do_ocr_word_mlp, do_ocr_word_svm

Alternatives

- create_lexicon

- lookup_lexicon, suggest_lexicon

Module

OCR/OCV

inspect_lexicon ( : : LexiconHandle : Words )

Query all words from a lexicon.

inspect_lexicon returns a tuple of all words in the lexicon in the parameter Words.

Parameters

- **LexiconHandle** (input_control) lexicon ~> handle
  Handle of the lexicon.

- **Words** (output_control) string(-array) ~> string
  List of all words.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
lookup_lexicon ( : : LexiconHandle, Word : Found )

Check if a word is contained in a lexicon.

lookup_lexicon checks whether Word is contained in the lexicon LexiconHandle, and returns 1 in Found if the word is found, otherwise 0.

Parameters

- **LexiconHandle** (input_control) Handle of the lexicon.
- **Word** (input_control) Word to be looked up.
  Default value: ‘word’
- **Found** (output_control) Result of the search.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

suggest_lexicon ( : : LexiconHandle, Word : Suggestion, NumCorrections )

Find a similar word in a lexicon.

suggest_lexicon compares Word to all words in the lexicon and calculates the minimum number of edit operations NumCorrections required to transform Word into a word from the lexicon. Valid edit operations are the insertion, deletion and replacement of characters. The most similar word found in the lexicon is returned in Suggestion. If there are multiple words with the same minimum number of corrections, only the first of those words is returned.

Parameters

- **LexiconHandle** (input_control) Handle of the lexicon.
- **Word** (input_control) Word to be looked up.
  Default value: ‘word’
- **Suggestion** (output_control) Most similar word found in the lexicon.

21.4 Neural Nets

\textbf{clear\_ocr\_class\_mlp} ( : : OCRHandle : )

Clear an OCR classifier.

clear\_ocr\_class\_mlp clears the OCR classifier given by OCRHandle that was created with create\_ocr\_class\_mlp and frees all memory required for the classifier. After calling clear\_ocr\_class\_mlp, the classifier can no longer be used. The handle OCRHandle becomes invalid.

- Parameters

  - OCRHandle (input\_control) \quad \text{ocr\_mlp\(-array)} \sim \text{handle}
    
    Handle of the OCR classifier.

- Result

  If OCRHandle is valid, the operator clear\_ocr\_class\_mlp returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

- Parallelization

  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

This operator modifies the state of the following input parameter:

  - OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

OCR/OCV
create_ocr_class_mlp ( : : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, NumHidden, Preprocessing, NumComponents, RandSeed : OCRHandle )

Create an OCR classifier using a multilayer perceptron.

create_ocr_class_mlp creates an OCR classifier that uses a multilayer perceptron (MLP). The handle of the OCR classifier is returned in OCRHandle.

For a description on how an MLP works, see create_class_mlp. create_ocr_class_mlp creates an MLP with OutputFunction = 'softmax'. The length of the feature vector of the MLP (NumInput in create_class_mlp) is determined from the features that are used for the OCR, which are passed in Features. The features are described below. The number of units in the hidden layer is determined by NumHidden. The number of output variables of the MLP (NumOutput in create_class_mlp) is determined from the names of the characters to be used in the OCR, which are passed in Characters. As described with create_class_mlp, the parameters Preprocessing and NumComponents can be used to specify a preprocessing of the data (i.e., the feature vectors). The OCR already approximately normalizes the features. Hence, Preprocessing can typically be set to 'none'. The parameter RandSeed has the same meaning as in create_class_mlp. Furthermore, like for general MLP classifiers (see create_class_mlp and set_regularization_params_class_mlp), it may be desirable to regularize OCR classifiers. This can be achieved by calling set_regularization_params_ocr_class_mlp before training the OCR classifier. In addition, like for general MLP classifiers (see create_class_mlp and set_rejection_params_class_mlp), it might be desirable to equip the OCR classifiers with the capability to reject unknown characters. The rejection class is by convention an additional symbol chr(26) that must be provided in Characters. The parameters of the rejection class can be set by calling set_rejection_params_ocr_class_mlp before training the OCR classifier.

The features to be used for the classification are determined by Features. Features can contain a tuple of several feature names. Each of these feature names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., 'pixel_invar'). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by WidthCharacter and HeightCharacter. The interpolation to be used for the transformation is determined by Interpolation. It has the same meaning as in affine_trans_image. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, Interpolation = 'constant' should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, large sizes will lead to the fact that small segmentation errors will have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, which leads to the fact that the character is zoomed differently than the characters in the training set. In most applications, sizes between 6 × 8 and 10 × 14 should be used.

The parameter Features can contain the following feature names for the classification of the characters.

'default' ratio and 'pixel_invar' are selected.

'pixel' Gray values of the character (WidthCharacter × HeightCharacter features).

'pixel_invar' Gray values of the character with maximum scaling of the gray values (WidthCharacter × HeightCharacter features).

'pixel_binary' Region of the character as a binary image zoomed to a size of WidthCharacter × HeightCharacter (WidthCharacter × HeightCharacter features).

'gradient_8dir' Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5 × 5 grid are extracted from each channel. These samples are used as features (200 features).

'projection_horizontal' Horizontal projection of the gray values (see gray_projections, HeightCharacter features).

'projection_horizontal_invar' Maximally scaled horizontal projection of the gray values (HeightCharacter features).

'projection_vertical' Vertical projection of the gray values (see gray_projections, WidthCharacter features).

'projection_vertical_invar' Maximally scaled vertical projection of the gray values (WidthCharacter features).
NEURAL NETS

'ratio'  Aspect ratio of the character (see height_width_ratio, 1 feature).
'anisometry'  Anisometry of the character (see eccentricity, 1 feature).
'width'  Width of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).
'height'  Height of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).
'zoom_factor'  Difference in size between the character and the values of WidthCharacter and HeightCharacter (not scale-invariant, 1 feature).
'foreground'  Fraction of pixels in the foreground (1 feature).
'foreground_grid_9'  Fraction of pixels in the foreground in a $3 \times 3$ grid within the smallest enclosing rectangle of the character (9 features).
'foreground_grid_16'  Fraction of pixels in the foreground in a $4 \times 4$ grid within the smallest enclosing rectangle of the character (16 features).
'compactness'  Compactness of the character (see compactness, 1 feature).
'convexity'  Convexity of the character (see convexity, 1 feature).
'moments_region_2nd_invar'  Normalized 2nd moments of the character (see moments_region_2nd_invar, 3 features).
'moments_region_2nd_rel_invar'  Normalized 2nd relative moments of the character (see moments_region_2nd_rel_invar, 2 features).
'moments_region_3rd_invar'  Normalized 3rd moments of the character (see moments_region_3rd_invar, 4 features).
'moments_central'  Normalized central moments of the character (see moments_region_central, 4 features).
'moments_gray_plane'  Normalized gray value moments and the angle of the gray value plane (see moments_gray_plane, 4 features).
'phi'  Sinus and cosinus of the orientation (angle) of the character (see elliptic_axis, 2 feature).
'num_connect'  Number of connected components (see connect_and_holes, 1 feature).
'num_holes'  Number of holes (see connect_and_holes, 1 feature).
'cooc'  Values of the binary cooccurrence matrix (see gen_cooc_matrix, 8 features).
'num_runs'  Number of runs in the region normalized by the height (1 feature).
'chord_histo'  Frequency of the runs per row (not scale-invariant, HeightCharacter features).

After the classifier has been created, it is trained using trainf_ocr_class_mlp. After this, the classifier can be saved using write_ocr_class_mlp. Alternatively, the classifier can be used immediately after training to classify characters using do_ocr_single_class_mlp or do_ocr_multi_class_mlp.

HALCON provides a number of pretrained OCR classifiers (see the “Solution Guide I”, chapter ‘OCR’, section ’Pretrained OCR Fonts’). These pretrained OCR classifiers can be read directly with read_ocr_class_mlp and make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Therefore, it is recommended to try if one of the pretrained OCR classifiers can be used successfully. If this is the case, it is not necessary to create and train an OCR classifier.

A comparison of the MLP and the support vector machine (SVM) (see create_ocr_class_svm) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

**Parameters**

WidthCharacter (input_control) ......................................................... integer ~ integer
Width of the rectangle to which the gray values of the segmented character are zoomed.

Default value: 8
Suggested values: WidthCharacter € [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20]
Typical range of values: $4 \leq \text{WidthCharacter} \leq 20$

HALCON 20.05.0.0
**HeightCharacter (input_control)** ....................................................... integer ~ integer
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default value: 10
Suggested values: HeightCharacter ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Typical range of values: 4 ≤ HeightCharacter ≤ 20

**Interpolation (input_control)** ......................................................... string ~ string
Interpolation mode for the zooming of the characters.
Default value: 'constant'
List of values: Interpolation ∈ ['nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted']

**Features (input_control)** ............................................................... string(-array) ~ string
Features to be used for classification.
Default value: 'default'
List of values: Features ∈ {'default', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir',
'projection_horizontal', 'projection_horizontal_invar', 'projection_vertical', 'projection_vertical_invar',
'ratio', 'anisometry', 'width', 'height', 'zoom_factor', 'foreground', 'foreground_grid_9',
'foreground_grid_16', 'compactness', 'convexity', 'moments_region_2nd_invar',
'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'moments_gray_plane',
'phi', 'num_connect', 'num_holes', 'cooc', 'num_runs', 'chord_histo'}

**Characters (input_control)** ......................................................... string-array ~ string
All characters of the character set to be read.
Default value: ['0','1','2','3','4','5','6','7','8','9']

**NumHidden (input_control)** ......................................................... integer ~ integer
Number of hidden units of the MLP.
Default value: 80
Suggested values: NumHidden ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 150}
Restriction: NumHidden >= 1

**Preprocessing (input_control)** ..................................................... string ~ string
Type of preprocessing used to transform the feature vectors.
Default value: 'none'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

**NumComponents (input_control)** .................................................. integer ~ integer
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = 'none' and
Preprocessing = 'normalization').
Default value: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

**RandSeed (input_control)** ............................................................ integer ~ integer
Seed value of the random number generator that is used to initialize the MLP with random values.
Default value: 42

**OCRHandle (output_control)** ...................................................... ocr_mlp ~ handle
Handle of the OCR classifier.

---

**Example**

```plaintext
read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
    Classes := [Classes, gen_tuple_const(20,chr(ord('a')+J))]
endfor
Classes := [Classes, gen_tuple_const(20,'.')]
```

write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 20, 
   'none', 81, 42, OCRHandle)
trainf_ocr_class_mlp (OCRHandle, 'letters.trf', 100, 0.01, 0.01, Error, 
   ErrorLog)
* Re-classify the characters in the image.
do_ocr_multi_class_mlp (Characters, Image, OCRHandle, Class, Confidence)

Result
If the parameters are valid, the operator create_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors
trainf_ocr_class_mlp, set_regularization_params_ocr_class_mlp,
set_rejection_params_ocr_class_mlp

deserialize_ocr_class_mlp ( : : SerializedItemHandle : OCRHandle )

Deserialize a serialized MLP-based OCR classifier.
deserialize_ocr_class_mlp deserializes a MLP-based OCR classifier, that was serialized by serialize_ocr_class_mlp (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

Parameters
▷ SerializedItemHandle (input_control) ......................... serialized_item ~ handle
   Handle of the serialized item.
▷ OCRHandle (output_control) .............................. ocr_mlp ~ handle
   Handle of the OCR classifier.

Result
If the parameters are valid, the operator deserialize_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

### `do_ocr_multi_class_mlp`

**Character**: Character, **Image**: Image : : OCRHandle : : Class, **Confidence**

Classify multiple characters with an OCR classifier.

`do_ocr_multi_class_mlp` computes the best class for each of the characters given by the regions `Character` and the gray values `Image` with the OCR classifier `OCRHandle` and returns the classes in `Class` and the corresponding confidences (probabilities) of the classes in `Confidence`. In contrast to `do_ocr_single_class_mlp`, `do_ocr_multi_class_mlp` can classify multiple characters in one call, and therefore typically is faster than a loop that uses `do_ocr_single_class_mlp` to classify single characters. However, `do_ocr_multi_class_mlp` can only return the best class of each character. Because the confidences can be interpreted as probabilities (see `classify_class_mlp` and `evaluate_class_mlp`), and it is therefore easy to check whether a character has been classified with too much uncertainty, this is usually not a disadvantage, except in cases where the classes overlap so much that in many cases the second best class must be examined to be able to decide the class of the character. In these cases, `do_ocr_single_class_mlp` should be used.

A string of the number `\032` (alternatively displayed as `\0x1A`) in `Class` signifies that the region has been classified as rejection class.

Before calling `do_ocr_multi_class_mlp`, the classifier must be trained with `trainf_ocr_class_mlp`.

#### Parameters

- **Character** (input_object) => object
  Characters to be recognized.
- **Image** (input_object) => singlechannelimage
  Gray values of the characters.
- **OCRHandle** (input_control) => ocr_mlp
  Handle of the OCR classifier.
- **Class** (output_control) => string
  Result of classifying the characters with the MLP.
- **Confidence** (output_control) => real
  Confidence of the class of the characters.

#### Result

If the parameters are valid, the operator `do_ocr_multi_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

#### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

OCR/OCV

---

**do_ocr_single_class_mlp** (Character, Image : : OCRHandle, Num : Class, Confidence)

Classify a single character with an OCR classifier.

do_ocr_single_class_mlp computes the best Num classes of the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Because multiple classes may be returned by do_ocr_single_class_mlp, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_mlp must be used. Because do_ocr_multi_class_mlp typically is faster than a loop with do_ocr_single_class_mlp and because the confidences can be interpreted as probabilities (see classify_class_mlp and evaluate_class_mlp), and it is therefore easy to check whether a character has been classified with too much uncertainty, in most cases do_ocr_multi_class_mlp should be used, unless the second-best class should be examined explicitly.

A string of the number ’\032’ (alternatively displayed as ’\0x1A’) in Class signifies that the region has been classified as rejection class.

Before calling do_ocr_single_class_mlp, the classifier must be trained with trainf_ocr_class_mlp.

---

**Parameters**

- **Character** (input_object) : Character to be recognized.
- **Image** (input_object) : Gray values of the character.
- **OCRHandle** (input_control) : Handle of the OCR classifier.
- **Num** (input_control) : Number of best classes to determine.

**Default value:** 1

**Suggested values:** Num ∈ {1, 2, 3, 4, 5}

- **Class** (output_control) : Result of classifying the character with the MLP.
- **Confidence** (output_control) : Confidence(s) of the class(es) of the character.

---

**Result**

If the parameters are valid, the operator do_ocr_single_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Possible Predecessors

trainf_ocr_class_mlp, read_ocr_class_mlp
do_ocr_word_mlp  ( Character, Image : : OCRHandle, Expression, 
                   NumAlternatives, NumCorrections : Class, Confidence, Word, 
                   Score )

Classify a related group of characters with an OCR classifier.

do_ocr_word_mlp works like do_ocr_multi_class_mlp insofar as it computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. In contrast to do_ocr_multi_class_mlp, do_ocr_word_mlp treats the group of characters as an entity which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or import_lexicon, by specifying the name of the lexicon in angular brackets as in ‘<mylexicon>’. If the Expression is of any other form, it is interpreted as a regular expression with the same syntax as specified for tuple_regexp_match. Note that you will usually want to use an expression of the form ‘^...$’ when using variable quantifiers like ‘*’, to ensure that the entire word is used in the expression. Also note that in contrast to tuple_regexp_match, do_ocr_word_mlp does not support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_mlp attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives used are identical to those returned by do_ocr_single_class_mlp for a single character. It does so by testing all possible corrections for which the classification result is changed for at most NumCorrections character regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

\[
Score = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\text{PenaltyCorrections} = \alpha \times \text{num_corr}
\]
\[
\text{PenaltyAlternatives} = \alpha \times \beta \times \text{num_alt}
\]

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

\[
\alpha = \frac{1}{\text{NumCorrections} + 1}
\]
\[
\beta = \frac{1}{\text{NumCorrections} \times (\text{NumAlternatives} - 1) + 2}
\]

Note that this is a combinatorial score which does not reflect the original Confidence of the best Class.
A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

- **Parameters**

  - **Character** (input_object) .................................................. region(-array) \( \sim \) object
    Characters to be recognized.
  - **Image** (input_object) .................................................. singlechannelimage \( \sim \) object : byte / uint2
    Gray values of the characters.
  - **OCRHandle** (input_control) ............................................. ocr_mlp \( \sim \) handle
    Handle of the OCR classifier.
  - **Expression** (input_control) ............................................. string \( \sim \) string
    Expression describing the allowed word structure.
  - **NumAlternatives** (input_control) .................................... integer \( \sim \) integer
    Number of classes per character considered for the internal word correction.
    **Default value:** 3
    **Suggested values:** \( \text{NumAlternatives} \in \{3, 4, 5\} \)
    **Typical range of values:** \( 1 \leq \text{NumAlternatives} \)
  - **NumCorrections** (input_control) ...................................... integer \( \sim \) integer
    Maximum number of corrected characters.
    **Default value:** 2
    **Suggested values:** \( \text{NumCorrections} \in \{1, 2, 3, 4, 5\} \)
    **Typical range of values:** \( 0 \leq \text{NumCorrections} \)
  - **Class** (output_control) .................................................. string(-array) \( \sim \) string
    Result of classifying the characters with the MLP.
    **Number of elements:** Class == Character
  - **Confidence** (output_control) .......................................... real(-array) \( \sim \) real
    Confidence of the class of the characters.
    **Number of elements:** Confidence == Character
  - **Word** (output_control) ................................................... string \( \sim \) string
    Word text after classification and correction.
  - **Score** (output_control) .................................................. real \( \sim \) real
    Measure of similarity between corrected word and uncorrected classification results.

- **Complexity**

  The complexity of checking all possible corrections is of magnitude \( O((n \ast a)^{\min(c,n)}) \), where \( a \) is the number of alternatives, \( n \) is the number of character regions, and \( c \) is the number of allowed corrections. However, to guard against a near-infinite loop in case of large \( n \), \( c \) is internally clipped to 5, 3, or 1 if \( a \ast n \geq 30 \), 60, or 90, respectively.

- **Result**

  If the parameters are valid, the operator `do_ocr_word_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

- **Parallelization**

  OCR/OCV
get_features_ocr_class_mlp ( Character : : OCRHandle, 
Transform : : Features )

Compute the features of a character.

get_features_ocr_class_mlp computes the features of the character given by Character with the OCR classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_mlp and do_ocr_multi_class_mlp, the character is passed as a single image object. Hence, before calling get_features_ocr_class_mlp, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_mlp for the classifier should be applied (Transform = 'true') or whether the untransformed features should be returned (Transform = 'false'). get_features_ocr_class_mlp can be used to inspect the features that are used for the classification.

Parameters

- Character (input_object) : singlechannelimage ~ object : byte / uint2
  Input character.
- OCRHandle (input_control) : ocr_mlp ~ handle
  Handle of the OCR classifier.
- Transform (input_control) : string ~ string
  Should the feature vector be transformed with the preprocessing?
  Default value: 'true'
  List of values: Transform ∈ {'true', 'false'}
- Features (output_control) : real-array ~ real
  Feature vector of the character.

Result

If the parameters are valid, the operator get_features_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

get_params_ocr_class_mlp ( : : OCRHandle : : WidthCharacter,
HeightCharacter, Interpolation, Features, Characters, NumHidden,
Preprocessing, NumComponents )

Return the parameters of an OCR classifier.

get_params_ocr_class_mlp returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_mlp. This is particularly useful if the classifier was read with read_ocr_class_mlp. The output of get_params_ocr_class_mlp can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_mlp.
Parameters

- **OCRHandle** (input_control) ................................. ocr_mlp ~ handle
  Handle of the OCR classifier.
- **WidthCharacter** (output_control) ........................ integer ~ integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.
- **HeightCharacter** (output_control) ........................ integer ~ integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.
- **Interpolation** (output_control) .......................... string ~ string
  Interpolation mode for the zooming of the characters.
- **Features** (output_control) ................................. string(-array) ~ string
  Features to be used for classification.
- **Characters** (output_control) ............................. string-array ~ string
  Characters of the character set to be read.
- **NumHidden** (output_control) .............................. integer ~ integer
  Number of hidden units of the MLP.
- **Preprocessing** (output_control) .......................... string ~ string
  Type of preprocessing used to transform the feature vectors.
- **NumComponents** (output_control) ......................... integer ~ integer
  Preprocessing parameter: Number of transformed features.

Result

If the parameters are valid, the operator `get_params_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

OCR/OCV

```cpp
get_prep_info_ocr_class_mlp ( : : OCRHandle, TrainingFile,
                             Preprocessing : InformationCont, CumInformationCont )
```

Compute the information content of the preprocessed feature vectors of an OCR classifier.

The operator `get_prep_info_ocr_class_mlp` computes the information content of the training vectors that have been transformed with the preprocessing given by `Preprocessing`. `Preprocessing` can be set to 'principal_components' or 'canonical_variates'. The OCR classifier `OCRHandle` must have been created with `create_ocr_class_mlp`. The preprocessing methods are described with `create_class_mlp`. The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (NumInput for 'principal_components' and min(NumOutput − 1, NumInput) for 'canonical_variates', see `create_class_mlp`), and is returned in `InformationCont` as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of `CumInformationCont`, i.e., `CumInformationCont` contains the
sums of the first \( n \) elements of \( \text{InformationCont} \). To use \text{get\_prep\_info\_ocr\_class\_mlp}, a sufficient number of samples must be stored in the training files given by \text{TrainingFile} (see \text{write\_ocr\_trainf}). \text{InformationCont} and \text{CumInformationCont} can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent \( x\% \) (e.g., 90\%) of the total data. This can be decided easily from the first value of \text{CumInformationCont} that lies above \( x\% \). The number thus obtained can be used as the value for \text{NumComponents} in a new call to \text{create\_ocr\_class\_mlp}. The call to \text{get\_prep\_info\_ocr\_class\_mlp} already requires the creation of a classifier, and hence the setting of \text{NumComponents} in \text{create\_ocr\_class\_mlp} to an initial value. However, if \text{get\_prep\_info\_ocr\_class\_mlp} is called it is typically not known how many components are relevant, and hence how to set \text{NumComponents} in this call. Therefore, the following two-step approach should typically be used to select \text{NumComponents}: In a first step, a classifier with the maximum number for \text{NumComponents} is created (\text{NumInput} for \text{'principal\_components'} and \( \min(\text{NumOutput} - 1, \text{NumInput}) \) for \text{'canonical\_variates'}). Then, the training samples are saved in a training file using \text{write\_ocr\_trainf}. Subsequently, \text{get\_prep\_info\_ocr\_class\_mlp} is used to determine the information content of the components, and with this \text{NumComponents}. After this, a new classifier with the desired number of components is created, and the classifier is trained with \text{trainf\_ocr\_class\_mlp}.

---

### Parameters

- **\text{OCRHandle}** (input\_control) \text{...} ocr\_mlp \text{\langle handle} Handle of the OCR classifier.
- **\text{TrainingFile}** (input\_control) \text{...} filename\_read(array) \text{\langle string} Names of the training files.
  - **Default value:** \text{\langle 'ocr.trf'}}
  - **File extension:** \text{.trf, .otr}
- **\text{Preprocessing}** (input\_control) \text{...} string \text{\langle string} Type of preprocessing used to transform the feature vectors.
  - **Default value:** \text{'principal\_components'}
  - **List of values:** \text{Preprocessing} \text{\in} \{ \text{'principal\_components', 'canonical\_variates'} \}
- **\text{InformationCont}** (output\_control) \text{...} real\_array \text{\langle real} Relative information content of the transformed feature vectors.
- **\text{CumInformationCont}** (output\_control) \text{...} real\_array \text{\langle real} Cumulative information content of the transformed feature vectors.

---

### Example

* Create the initial OCR classifier.
  ```
  read\_ocr\_trainf\_names ('ocr.trf', CharacterNames, CharacterCount)
  create\_ocr\_class\_mlp (8, 10, 'constant', 'default', CharacterNames, 80, \( 'canonical\_variates', \|CharacterNames\|, 42, OCRHandle)
  ```
* Get the information content of the transformed feature vectors.
  ```
  get\_prep\_info\_ocr\_class\_mlp (OCRHandle, 'ocr.trf', 'canonical\_variates', \( InformationCont, CumInformationCont)
  ```
* Determine the number of transformed components.
  * \text{NumComp} = [...]
* Create the final OCR classifier.
  ```
  create\_ocr\_class\_mlp (8, 10, 'constant', 'default', CharacterNames, 80, \( 'canonical\_variates', \text{NumComp}, 42, OCRHandle)
  ```
* Train the final classifier.
  ```
  trainf\_ocr\_class\_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, ErrorLog)
  ```
* Write the trained classifier.
  ```
  write\_ocr\_class\_mlp (OCRHandle, 'ocr.omc')
  ```

---

### Result

If the parameters are valid, the operator \text{get\_prep\_info\_ocr\_class\_mlp} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

\text{get\_prep\_info\_ocr\_class\_mlp} may return the error 9211 (Matrix is not positive definite) if \text{Preprocessing} = \text{'canonical\_variates'} is used. This typically indicates that not enough training samples have been stored for each class.

Possible Successors

Module

---

read_ocr_class_mlp ( : : FileName : OCRHandle )

Read an OCR classifier from a file.

read_ocr_class_mlp reads an OCR classifier that has been stored with write_ocr_class_mlp. Since the training of an OCR classifier can consume a relatively long time, the classifier is typically trained in an offline process and written to a file with write_ocr_class_mlp. In the online process the classifier is read with read_ocr_class_mlp and subsequently used for classification with do_ocr_single_class_mlp or do_ocr_multi_class_mlp.

HALCON provides a number of pretrained OCR classifiers (see the “Solution Guide I”, chapter ‘OCR’, section ‘Pretrained OCR Fonts’). These pretrained OCR classifiers make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Note that the pretrained OCR classifiers were trained with symbols that are printed dark on light.

Parameters

- **FileName** (input_control) : filename.read
  File name.

Module

OCR/OCV

select_feature_set_trainf_mlp ( : : TrainingFile, FeatureList,
SelectionMethod, Width, Height, GenParamName,
GenParamValue : OCRHandle, FeatureSet, Score )

Selects an optimal combination of features to classify OCR data.

select_feature_set_trainf_mlp selects an optimal combination of features, to classify the OCR data given in the training file TrainingFile with a multilayer perceptron, for details see create_ocr_class_mlp.

Possible features are all OCR features listed and explained in create_ocr_class_mlp. All candidates which should be tested can be specified in FeatureList. A subset of these features is returned as selected features in FeatureSet.

select_feature_set_trainf_mlp is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator select_feature_set_mlp.

The selection method SelectionMethod is either a greedy search 'greedy' (iteratively add the feature with highest gain) or the dynamically oscillating search 'greedy_oscillating' (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method 'greedy' is generally preferable, since it is faster. Only in cases when a large training set is available the method 'greedy_oscillating' might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.
The parameters `GenParamName` and `GenParamValue` allow to adapt the setting of the number of hidden neurons in the MLP with `num_hidden`. The default value is 80, a higher value leads to longer training times but might lead to a more expressive classifier.

---

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_trainf_mlp` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

---

Parameters

- **TrainingFile**
  - Type: `filename.read(-array) ~ string`
  - Description: Names of the training files.
  - Default value: 
  - File extension: `.trf`, `.otr`

- **FeatureList**
  - Type: `string(-array) ~ string`
  - Description: List of features that should be considered for selection.
  - Default value: 
  - List of values:
    - `zoom_factor`, `ratio`, `width`, `height`, `foreground`, `foreground_grid_9`, `foreground_grid_16`, `anisometry`, `compactness`, `convexity`, `moments_region_2nd_invar`, `moments_region_2nd_rel_invar`, `moments_region_3rd_invar`, `moments_central`, `phi`, `num_connect`, `num_holes`, `projection_horizontal`, `projection_vertical`, `projection_horizontal_invar`, `projection_vertical_invar`, `chord_histo`, `num_runs`, `pixel`, `pixel_invar`, `pixel_binary`, `gradient_8dir`, `cooc`, `moments_gray_plane`

- **SelectionMethod**
  - Type: `string`
  - Description: Method to perform the selection.
  - Default value: `greedy`
  - List of values: `SelectionMethod ∈ {'greedy', 'greedy_oscillating'}`

- **Width**
  - Type: `integer` ~ `integer`
  - Description: Width of the rectangle to which the gray values of the segmented character are zoomed.
  - Default value: 15

- **Height**
  - Type: `integer` ~ `integer`
  - Description: Height of the rectangle to which the gray values of the segmented character are zoomed.
  - Default value: 16

- **GenParamName**
  - Type: `string-array ~ string`
  - Description: Names of generic parameters to configure the selection process and the classifier.
  - Default value: 
  - List of values: `GenParamName ∈ {'nu'}`

- **GenParamValue**
  - Type: `number-array ~ real / integer / string`
  - Description: Values of generic parameters to configure the selection process and the classifier.
  - Default value: 
  - Suggested values: `GenParamValue ∈ {'0.1'}`

- **OCRHandle**
  - Type: `ocr_mlp ~ handle`
  - Description: Trained OCR-MLP classifier.

- **FeatureSet**
  - Type: `string-array ~ string`
  - Description: Selected feature set, contains only entries from `FeatureList`.

- **Score**
  - Type: `real-array ~ real`
  - Description: Achieved score using tow-fold cross-validation.

---

Result

If the parameters are valid, the operator `select_feature_set_trainf_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

Parallelization
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module
OCR/OCV

select_feature_set_trainf_mlp_protected ( : : TrainingFile,
Password, FeatureList, SelectionMethod, Width, Height,
GenParamName, GenParamValue : OCRHandle, FeatureSet, Score )

Select an optimal combination of features to classify OCR data from a (protected) training file.

select_feature_set_trainf_mlp_protected selects an optimal combination of features to classify the data given in the training files TrainingFile with a multilayer perceptron (MLP). Its functionality corresponds to the functionality of select_feature_set_trainf_mlp, with the addition that select_feature_set_trainf_mlp_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator’s functionality see select_feature_set_trainf_mlp. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Attention
This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_mlp_protected may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ TrainingFile (input_control) .......................................................... filename.read(-array) ˜ string
Names of the training files.
Default value: ”
File extension: .trf, .otr
▷ Password (input_control) .......................................................... string(-array) ˜ string
Passwords for protected training files.
▷ FeatureList (input_control) ......................................................... string(-array) ˜ string
List of features that should be considered for selection.
Default value:
SelectionMethod (input_control)  .................................................. string  ~ string
Method to perform the selection.
Default value: ’greedy’
List of values: SelectionMethod ∈ ['greedy', 'greedy_oscillating']

Width (input_control)  ........................................................ integer  ~ integer
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default value: 15

Height (input_control)  ......................................................... integer  ~ integer
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default value: 16

GenParamName (input_control)  ............................................. string-array  ~ string
Names of generic parameters to configure the selection process and the classifier.
Default value: []
List of values: GenParamName ∈ ['nu']

GenParamValue (input_control)  ........................................... number-array  ~ real / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default value: []
Suggested values: GenParamValue ∈ [0.1]

OCRHandle (output_control)  ................................................. ocr_mlp  ~ handle
Trained OCR-MLP classifier.

FeatureSet (output_control)  ............................................... string-array  ~ string
Selected feature set, contains only entries from FeatureList.

Score (output_control)  ....................................................... real-array  ~ real
Achieved score using tow-fold cross-validation.

If the parameters are valid, the operator select_feature_set_trainf_mlp_protected returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Result

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

OCR/OCV

serialize_ocr_class_mlp ( : : OCRHandle : SerializedItemHandle )

Serialize a MLP-based OCR classifier.
serialize_ocr_class_mlp serializes a MLP-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocr_class_mlp is converted to a serialized item. The OCR classifier is defined by the handle OCRHandle. The serialized OCR classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocr_class_mlp.
21.4. NEURAL NETS

Parameters

- **OCRHandle** (input_control)  
  Handle of the OCR classifier.

- **SerializedItemHandle** (output_control)  
  Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

```cpp
set_regularization_params_ocr_class_mlp ( : : OCRHandle,
                                           GenParamName, GenParamValue : )
```

Set the regularization parameters of an OCR classifier.

`set_regularization_params_ocr_class_mlp` sets the regularization parameters of the OCR classifier passed in `OCRHandle`. The regularization parameter to be set is specified with `GenParamName`. Its value is specified with `GenParamValue`.

As described at `create_class_mlp`, it may be desirable to regularize the OCR classifier (i.e., the MLP of the OCR classifier) to enforce a smoother transition of the confidences between the different classes and to prevent overfitting of the OCR classifier to the training data. To achieve this, a penalty for large MLP weights (which are the main reason for very sharp transitions between classes) can be added to the training of the OCR classifier in `trainf_ocr_class_mlp` by setting `GenParamName` to ‘weight_prior’ and setting `GenParamValue` to a value > 0. Furthermore, the regularization parameters can be determined automatically. For details, see `set_regularization_params_class_mlp`. If the regularization parameters should be determined automatically, please carefully note the advice in `set_regularization_params_class_mlp` on how to select the parameters `NumHidden` of the MLP and ‘num_outer_iterations’ and on the memory and runtime implications of automatically determining the regularization parameters on the runtime of the training of the OCR classifier.

Parameters

- **OCRHandle** (input_control)  
  Handle of the OCR classifier.

- **GenParamName** (input_control)  
  Name of the regularization parameter to return.

  **Default value:** ‘weight_prior’

  **List of values:** `GenParamName ∈ {'weight_prior', 'num_outer_iterations', 'num_inner_iterations'}`

- **GenParamValue** (input_control)  
  Value of the regularization parameter.

  **Default value:** 1.0

  **Suggested values:** `GenParamValue ∈ {0.01, 0.1, 1.0, 10.0, 100.0, 0, 1, 2, 3, 5, 10, 15, 20}`

OCR/OCV

set_rejection_params_ocr_class_mlp ( : : OCRHandle, GenParamName, GenParamValue : )

Set the rejection class parameters of an OCR classifier.

set_rejection_params_ocr_class_mlp sets the rejection class parameters of the OCR classifier passed in OCRHandle. The parameter to be set is specified with GenParamName. Its value is specified with GenParamValue. For some OCR applications it is important to know, if a letter to be classified is similar to the training set or not. If a letter is different to the training set, then it can be classified a rejection class. This additional rejection class must be specified as an additional character in create_ocr_class_mlp. For details on how to specify a rejection class, see set_rejection_params_class_mlp.

--- Parameters ---

▶ OCRHandle (input_control) ………………………………………………………… ocr_mlp ˜ handle Handle of the OCR classifier.
▶ GenParamName (input_control) …………………………………………………… string(-array) ˜ string Name of the general parameter.
   Default value: 'sampling_strategy'
   List of values: GenParamName ∈ ['sampling_strategy', 'hyperbox_tolerance', 'rejection_sample_factor', 'random_seed', 'rejection_class_index']
▶ GenParamValue (input_control) …………………………………………………… string(-array) ˜ string Value of the general parameter.
   Default value: 'hyperbox_around_all_classes'
   List of values: GenParamValue ∈ ['no_rejection_class', 'hyperbox_around_all_classes', 'hyperbox_around_each_class', 'hyperbox_ring_around_each_class']
If the parameters are valid, the operator `set_rejection_params_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- `trainf_ocr_class_mlp`

**Module**

`trainf_ocr_class_mlp` ( : : OCRHandle, TrainingFile, MaxIterations, WeightTolerance, ErrorTolerance : Error, ErrorLog )

*Train an OCR classifier.*

`trainf_ocr_class_mlp` trains the OCR classifier `OCRHandle` with the training characters stored in the OCR training files given by `TrainingFile`. The training files must have been created, e.g., using `write_ocr_trainf`, before calling `trainf_ocr_class_mlp`.

The remaining parameters have the same meaning as in `train_class_mlp` and are described in detail with `train_class_mlp`. A regularization of the OCR classifier and an automatic determination of the regularization parameters (see `set_regularization_params_ocr_class_mlp`) is taken into account during the training. Furthermore, if a rejection class has been specified using `set_rejection_params_ocr_class_mlp`, before the actual training the samples for the rejection class are generated.

Please note that training characters that have no corresponding class in the classifier `OCRHandle` are discarded.

**Parameters**

- **OCRHandle** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ocr_mlp `handle`
  Handle of the OCR classifier.

- **TrainingFile** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . filename.read(-array) `string`
  Names of the training files.
  Default value: ’ocr.trf’
  File extension: .trf, .otr

- **MaxIterations** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer `integer`
  Maximum number of iterations of the optimization algorithm.
  Default value: 200
  Suggested values: `MaxIterations ∈ [20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300]`

- **WeightTolerance** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real `real`
  Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.
  Default value: 1.0
  Suggested values: `WeightTolerance ∈ [1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001]`
  Restriction: `WeightTolerance >= 1.0e-8`
21.4. NEURAL NETS

ErrorTolerance (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real \to real
Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.

Default value: 0.01
Suggested values: ErrorTolerance \in \{1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001\}
Restriction: ErrorTolerance \geq 1.0e-8

Error (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real \to real
Mean error of the MLP on the training data.

ErrorLog (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real-array \to real
Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

Example

* Train an OCR classifier
  read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
  create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, 
    'none', 81, 42, OCRHandle)
  trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, ErrorLog)
  write_ocr_class_mlp (OCRHandle, 'ocr.omc')

If the parameters are valid, the operator trainf_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

trainf_ocr_class_mlp may return the error 9211 (Matrix is not positive definite) if Preprocessing = 'canonical_variates' is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change Preprocessing to 'normalization'. Another solution can be to add more training samples.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module
OCR/OCV

Train an OCR classifier with data from a (protected) training file.
trainf_ocr_class_mlp_protected trains the OCR classifier OCRHandle with the training data stored in the OCR training files given by TrainingFile. Its functionality corresponds to the functionality of trainf_ocr_class_mlp, with the addition that trainf_ocr_class_mlp_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator’s functionality see trainf_ocr_class_mlp. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Parameters

- **OCRHandle** (input_control) \( \Rightarrow \) ocr_mlp \( \Rightarrow \) handle
  Handle of the OCR classifier.

- **TrainingFile** (input_control) \( \Rightarrow \) filename.read(-array) \( \Rightarrow \) string
  Names of the training files.
  Default value: ‘ocr.trf’
  File extension: .trf, .otr

- **Password** (input_control) \( \Rightarrow \) string(-array) \( \Rightarrow \) string
  Passwords for protected training files.

- **MaxIterations** (input_control) \( \Rightarrow \) integer \( \Rightarrow \) integer
  Maximum number of iterations of the optimization algorithm.
  Default value: 200
  Suggested values: MaxIterations \( \in \) \{20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300\}

- **WeightTolerance** (input_control) \( \Rightarrow \) real \( \Rightarrow \) real
  Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.
  Default value: 1.0
  Suggested values: WeightTolerance \( \in \) \{1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001\}
  Restriction: WeightTolerance >= 1.0e-8

- **ErrorTolerance** (input_control) \( \Rightarrow \) real \( \Rightarrow \) real
  Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.
  Default value: 0.01
  Suggested values: ErrorTolerance \( \in \) \{1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001\}
  Restriction: ErrorTolerance >= 1.0e-8

- **Error** (output_control) \( \Rightarrow \) real \( \Rightarrow \) real
  Mean error of the MLP on the training data.

- **ErrorLog** (output_control) \( \Rightarrow \) real-array \( \Rightarrow \) real
  Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

Result

If the parameters are valid, the operator trainf_ocr_class_mlp_protected returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

trainf_ocr_class_mlp_protected may return the error 9211 (Matrix is not positive definite) if Preprocessing = ‘canonical_variates’ is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change Preprocessing to ‘normalization’. ### clear_text_model

**Clear a text model.**
clear_text_model clears the text model in TextModel and frees all underlying memory.

Parameters

\[ TextModel \text{ (input\_control) \rightarrow handle} \]

- Text model to be cleared.

Result
clear_text_model returns the value 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_text_model_reader

Module

OCR/OCV

---

clear_text_result ( : : TextResultID : )

Clear a text result.

clear_text_result clears the text result in TextResultID and frees all underlying memory.

Parameters

\[ TextResultID \text{ (input\_control) \rightarrow handle} \]

- Text result to be cleared.

Result
clear_text_result returns the value 2 (H_MSG_TRUE).

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextResultID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

create_text_model_reader ( : : Mode, OCRClassifier : TextModel )

Create a text model.
create_text_model_reader creates a TextModel, which describes the text to be segmented with find_text.

The parameter value of Mode determines which text segmentation approach is used. Possible values are 'auto' and 'manual'.

Typically, the parameter Mode should be set to 'auto' because this mode is more stable and requires less configuration effort. Note that in this case, also an OCR classifier must be passed in OCRClassifier. Only if one of the following restrictions applies, Mode must be set to 'manual':

- The segmentation of text which has strong local variations of the polarity is required. For example, due to reflections, engraved text often has strong local variations.
- No suitable OCR classifier is available (see below).

If Mode = 'auto', find_text is able to extract text of arbitrary size. It is possible to restrict the search to characters with specific attributes, see set_text_model_param for details. Particulariy, if the text to be segmented contains dot printed characters, the text model parameter 'dot_print' must be set to 'true'. Furthermore, an OCR classifier must be passed in OCRClassifier. This OCR classifier must be based on a convolutional neural network (CNN) or a multilayer perceptron (MLP). Moreover, it is strongly recommended to use a CNN based OCR classifier with rejection class or a MLP based classifiers that has been trained with regularization parameters (see set_regularization_params_ocr_class_mlp and provides a rejection class (see set_rejection_params_ocr_class_mlp). A suitable OCR classifier can either be read with read_ocr_class_cnn or read_ocr_class_mlp, or be created with create_ocr_class_mlp. It is also possible to pass a string containing the path to a pretrained OCR classifier or an OCR classifier that has been stored with write_ocr_class_mlp.

To enable text segmentation when Mode = 'manual', reasonable parameters for the text model, including the expected character height and width, must be set using set_text_model_param. In this case, the value of OCRClassifier is ignored.

The parameters of the TextModel can be set and queried with set_text_model_param and get_text_model_param. Since memory is allocated for the text model during the call of create_text_model_reader and during the following operations, the model should be freed explicitly by the operator clear_text_model as soon as it is no longer used.

--- Example ---

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
fund_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

Result
create_text_model_reader returns the value 2 (H_MSG_TRUE).

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors
set_text_model_param, get_text_model_param, find_text

See also
clear_text_model

Module

OCR/OCV

____ find_text ( Image : TextModel : TextResultID )____

Find text in an image.

find_text finds text specified by the TextModel in the Image and returns the result in TextResultID. Specific results of TextResultID can be obtained with get_text_result and get_text_object.

The text results in TextResultID differ, depending on how Mode was set when creating the TextModel with create_text_model_reader.

For a text model with Mode = 'auto' find_text extracts and classifies text of arbitrary size within the Image. It is possible to restrict the search to characters with specific attributes, see set_text_model_param for details.

For a text model with Mode = 'manual' reasonable parameters for the text model, including the expected character height and width, need to be set using set_text_model_param. Furthermore, the Image is preprocessed such that character like structures are enhanced. The resulting compensated image can be queried from TextResultID if 'persistence' was set to 'true' in TextModel.

Both the text models with Mode = 'auto' and Mode = 'manual' apply various thresholds to the input image and segment character candidates based on region and gray value features. These candidates are further clustered to lines. Each line is individually completed and tested if it fulfills the constraints of a text line. Text models with Mode set to 'auto' require a text line to consist of at least two characters, whereas text models with Mode set to 'manual' require a text line to consist of at least three characters. In a further step, punctuations and separators are added if the correspondent parameters were set via set_text_model_param. Finally, if TextModel contains 'text_line_structure' entries, the completed line is fitted to these structures.

find_text finds text which is roughly horizontally aligned in Image. text_line_orientation and rotate_image can be used to achieve this alignment.

Since memory is allocated for the text result during the call of find_text and during the following operations, the text result should be freed explicitly by the operator clear_text_result as soon as it is no longer used.
Parameters

- **Image** (input_object) ................................. singlechannelimage ∼ object : byte / uint2
  Input image.
- **TextModel** (input_control) .......................... text_model ∼ handle
  Text model specifying the text to be segmented.
- **TextResultID** (output_control) ...................... text_result ∼ handle
  Result of the segmentation.

Example

```plaintext
read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)
```

Result

If the parameters are valid, the operator `find_text` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

### get_text_model_param

```plaintext
get_text_model_param ( : : TextModel, 
                       GenParamName : GenParamValue )
```

Query parameters of a text model.

get_text_model_param queries the parameters of `TextModel`. With the exception of `ocr_classifier`, all valid parameters can be queried. See `set_text_model_param` for a detailed description of the possible values for `GenParamName` and `GenParamValue`.

Parameters

- **TextModel** (input_control) .......................... text_model ∼ handle
  Text model.
- **GenParamName** (input_control) ........................ string ∼ string
  Parameters to be queried.
  **Default value:** 'min_contrast'
  **Suggested values:** `GenParamName ∈ { 'add_fragments', 'dot_print', 'dot_print_max_dot_gap', 'dot_print_min_char_gap', 'dot_print_tight_char_spacing', 'eliminate_border_blobs', 'max_char_height', ... }`

HALCON 20.05.0.0
Values of Parameters.

If the input parameters are set correctly, the operator `get_text_model_param` returns the value 2 (H_MSG_TRUE). Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_text_model_param` Module

OCR/OCV

```
get_text_object ( : Characters : TextResultID, ResultName : )
```

Query an iconic value of a text segmentation result.

`get_text_object` queries the iconic result `ResultName` of `TextResultID` returned by `find_text`. The possible parameter values for `ResultName` differ, depending on the text model used within the text segmentation process of `find_text`.

In the following, first the possible parameter values for text models with `Mode = 'auto'` are listed, and then those for text models with `Mode = 'manual'`.

The following results can be queried:

- **Result objects for text segmentation with text models with Mode = 'auto'**
  For each polarity, the text lines are independently sorted from top to bottom and left to right. The character within the text lines are sorted from left to right.
  - `all_lines`: Returns all characters in all segmented text lines.
  - `['line', LIN_INDEX]`: Returns all characters within the text line specified by `LIN_INDEX`. For example, `['line', 0]` returns the first line.
  - `['element', INDEX]`: Returns the character at position `INDEX`. For example, `['element', 0]` returns the first character.

- **Result objects for text segmentation with text models with Mode = 'manual'**
  - `manual_all_lines`: Returns all characters in all segmented text lines. The text lines are sorted from top to bottom and left to right. The characters within the text lines are sorted from left to right.
  - `['manual_line', INDEX]`: Returns all characters within the text line specified by `INDEX` (e.g. `['manual_line', 0]` to return the first line). The characters within the text line are sorted from left to right.

If 'manual_persistence' was activated for the text model used to create `TextResultID`, the following additional value can be queried:
  - `manual_compensated_image`: the enhanced image used for segmentation.

21.5. SEGMENTATION

Parameters

- **Characters** (output_object) ................................. object(-array)  \(\sim\) object
  Returned result.
- **TextResultID** (input_control) ............................ text_result  \(\sim\) handle
  Text result.
- **ResultName** (input_control) ............................. string(-array)  \(\sim\) string / integer
  Name of the result to be returned.
  **Default value:** 'all_lines'
  **List of values:** ResultName \(\in\) {'all_lines', 'element', 'line', 'manual_all_lines', 'manual_line', 'manual_compensated_image'}

Example

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
  set_text_model_param (TextModel, 'min_char_height', 20)
  find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
  get_text_object (Characters, TextResultID, 'all_lines')
  get_text_result (TextResultID, 'class', Class)

Result

If the parameters are valid, the operator get_text_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_text_result

Module

Foundation

get_text_result ( : : TextResultID, ResultName : ResultValue )

Query a control value of a text segmentation result.

get_text_result queries the control result ResultName of TextResultID returned by find_text. The possible parameter values for ResultName differ, depending on the text model used within the text segmentation process of find_text.

In the following, first the possible parameter values for text models with Mode = 'auto' are listed, and then those for text models with Mode = 'manual'.

The following results can be queried:

- **Results for text segmentation with text models with Mode = 'auto'**
  For each polarity, the text lines are independently sorted from top to bottom and left to right. The character within the text lines are sorted from left to right.
  
  'num_lines': Number of lines found.

HALCON 20.05.0.0
'num_classes': Number of best classes stored for each character. Depending on the number of classes of the used classifier this value might be smaller than the one set in the text model, see \texttt{set_text_model_param}.

'class': Classification results of all segmented characters with the OCR classifier contained in the corresponding text model. Note that if the classifier was trained with rejection class, \texttt{get_text_result} returns the second best result for characters that are classified as rejection class.

['class', n]: Similar to 'class', except that the class with the \((n+1)\)-highest confidence is returned. For example, ['class', 0] returns for each character the class with the highest confidence. Moreover, in contrast to 'class', the rejection class can be returned if the classifier contained in the corresponding text model was trained with rejection class.

['class_line', LineIndex]: Classification results of the characters within the text line specified by LineIndex with the OCR classifier contained in the corresponding text model. For example, ['class_line', 0] returns the character classes within the first text line. Note that if the classifier was trained with rejection class, \texttt{get_text_result} returns the second best result for characters that are classified as rejection class.

['class_line', LineIndex, n]: Similar to ['class_line', LineIndex], except that the classes with the \((n+1)\)-highest confidences are returned. For example, ['class_line', LineIndex, 0] returns for each character in the text line specified by LineIndex the class with the highest confidence. Moreover, in contrast to ['class_line', LineIndex], the rejection class can be returned if the classifier contained in the corresponding text model was trained with rejection class.

['class_element', Index]: Classification result of the character at position Index with the OCR classifier contained in the corresponding text model. For example ['class_element', 0] returns the 'num_classes' best classes (sorted by confidence) of the first character.

'confidence': Returns the confidences of the classes for all segmented characters, see 'class'.

['confidence', n]: Returns the confidences of the classes with the \((n+1)\)-highest confidences, see ['class', n].

['confidence_line', LineIndex]: Returns the confidences of the classes of all characters within the text line specified by LineIndex, see ['class_line', LineIndex].

['confidence_line', LineIndex, n]: Returns the confidences of the classes with the \((n+1)\)-highest confidence for all characters within the text line specified by LineIndex, see ['class_line', LineIndex, n].

['confidence_element', Index]: Returns the confidences corresponding to the classes of the character at position Index, see ['class_element', Index].

'polarity': Returns the polarity of all segmented characters.

['polarity_line', LineIndex]: Returns the polarity of the characters in the segmented text line specified by LineIndex. For example, ['polarity_line', 0] returns the polarity within the first text line.

['polarity_element', Index]: Returns the polarity of the character at the position Index. For example ['polarity_char', 0] returns the polarity of the first character.

• Results for text segmentation with text models with Mode = 'manual'

'manual_num_lines': Number of lines found.

If 'manual_persistence' was activated for the text model used to create TextResultID, the following additional value can be queried:

'manual_thresholds': The thresholds used for segmentation.
21.5. SEGMENTATION

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

Result
If the parameters are valid, the operator get_text_result returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

get_text_object

Module

segment_characters ( Region, Image : ImageForeground,
RegionForeground : Method, EliminateLines, DotPrint, StrokeWidth,
CharWidth, CharHeight, ThresholdOffset, Contrast : UsedThreshold )

Segments characters in a given region of an image.

This operator is used to segment characters in a given Region of an Image. The Region is only used to reduce the working area. The segmented characters are returned in RegionForeground.

Two different methods to detect the characters are supplied. All segmentation methods assume that the text ist darker than the background. If this is not the case, please invert the image with invert_image.

The parameter Method determines the algorithm for text segmentation. The possible values are

'local_contrast_best' This method extracts text that differ locally from the background. Therefore, it is suited for images with inhomogeneous illumination. The enhancement of the text borders, leads to a more accurate determination of the outline of the text. Which is especially useful if the background is highly textured. The parameter Contrast defines the minimum contrast, i.e., the minimum gray value difference between symbols and background.

'local_auto_shape' The minimum contrast is estimated automatically such that the number of very small regions is reduced. This method is especially suitable for noisy images. The parameter ThresholdOffset can be used to adjust the threshold. Let \( g(x,y) \) be the gray value at position \((x,y)\) in the input Image. The threshold condition is determined by:

\[
g(x,y) \leq \text{UsedThreshold} + \text{ThresholdOffset}.
\]

Select EliminateLines if the extraction of characters is disturbed by lines that are horizontal or vertical with respect to the lines of text and set its value to 'true'. The elimination is influenced by the maximum of CharWidth and the maximum of CharHeight. For further information see the description of these parameters.

DotPrint: Should be set to 'true' if dot prints should be read, else to 'false'.

StrokeWidth: Specifies the stroke width of the text. It is used to calculate internally used mask sizes to determine the characters. This mask sizes are also influenced through the parameters DotPrint, the average CharWidth, and the average CharHeight.
CharWidth: This can be a tuple with up to three values. The first value is the average width of a character. The second is the minimum width of a character and the third is the maximum width of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on the average CharWidth. The same is the case if the maximum is not set. Some examples:

[10] sets the average character width to 10, the minimum and maximum are calculated by the operator.
[10,-1,20] sets the average character width to 10, the minimum value is calculated by the system, and the maximum is set to 20.
[10,5,20] sets the average character width to 10, the minimum to 5, and the maximum to 20.

CharHeight: This can be a tuple with up to three values. The first value is the average height of a character. The second is the minimum height of a character and the third is the maximum height of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on the average CharHeight. The same is the case if the maximum is not set. Some examples:

[10] sets the average character height to 10, the minimum and maximum are calculated by the operator.
[10,-1,20] sets the average character height to 10, the minimum value is calculated by the system, and the maximum is set to 20.
[10,5,20] this sets the average character height to 10, the minimum to 5, and the maximum to 20.

ThresholdOffset: This parameter can be used to adjust the threshold, which is used when the segmentation method 'local_auto_shape' is chosen.

Contrast: Defines the minimum contrast between the text and the background. This parameter is used if the segmentation method 'local_contrast_best' is selected.

UsedThreshold: After the execution, this parameter returns the threshold used to segment the characters.

ImageForeground returns the image that was internally used for the segmentation.

---

Parameters

- **Region** (input_object) region(-array) ~ object
  Area in the image where the text lines are located.

- **Image** (input_object) singlechannelimage ~ object : byte / uint2
  Input image.

- **ImageForeground** (output_object) image(-array) ~ object : byte / uint2
  Image used for the segmentation.

- **RegionForeground** (output_object) singlechannelregion(-array) ~ object
  Region of characters.

- **Method** (input_control) string ~ string
  Method to segment the characters.
  Default value: 'local_auto_shape'
  List of values: Method ∈ {'local_contrast_best', 'local_auto_shape'}

- **EliminateLines** (input_control) string ~ string
  Eliminate horizontal and vertical lines?
  Default value: 'false'
  List of values: EliminateLines ∈ {'true', 'false'}

- **DotPrint** (input_control) string ~ string
  Should dot print characters be detected?
  Default value: 'false'
  List of values: DotPrint ∈ {'true', 'false'}

- **StrokeWidth** (input_control) string ~ string
  Stroke width of a character.
  Default value: 'medium'
  List of values: StrokeWidth ∈ {'ultra_light', 'light', 'medium', 'bold'}

- **CharWidth** (input_control) integer-array ~ integer
  Width of a character.
  Default value: 25
  Typical range of values: 1 ≤ CharWidth
  Restriction: CharWidth >= 1
CharHeight (input_control) .......................................................... integer-array ~ integer
Height of a character.
Default value: 25
Typical range of values: 1 ≤ CharHeight
Restriction: CharHeight >= 1
ThresholdOffset (input_control) .................................................... integer ~ integer
Value to adjust the segmentation.
Default value: 0
Contrast (input_control) ............................................................. integer ~ integer
Minimum gray value difference between text and background.
Default value: 10
Typical range of values: 1 ≤ Contrast
Restriction: Contrast >= 1
UsedThreshold (output_control) ..................................................... integer(-array) ~ integer
Threshold used to segment the characters.

Example

for Index := 1 to 5 by 1
  read_image (Image, 'dot_print_rotated/dot_print_rotated_' + Index$'02d')
text_line_orientation (Image, Image, 50, rad(-30), rad(30), OrientationAngle)
rotate_image (Image, ImageRotate, deg(-OrientationAngle), 'constant')
segment_characters (ImageRotate, ImageRotate, ImageForeground, \RegionForeground, 'local_auto_shape', 'false', 'false', 'medium', \25, 25, 0, 10, UsedThreshold)
endfor

Result

If the input parameters are set correctly, the operator segment_characters returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors

Possible Successors

Alternatives

Module

select_characters ( Region : RegionCharacters : DotPrint, \StrokeWidth, CharWidth, CharHeight, Punctuation, DiacriticMarks, \PartitionMethod, PartitionLines, FragmentDistance, \ConnectFragments, ClutterSizeMax, StopAfter : )

Selects characters from a given region.

select_characters selects from a given Region the areas which might be characters and returns them in RegionCharacters. This is done by using features like StrokeWidth, DotPrint, the size of the characters and some more. The given Region should be united, else every Region is processed separately. Thus do not call connection before calling select_characters, because then fragments or dots would not be
connected to a character. If you have more than one region with text, you can of course handle them without merging them. The Region for select_characters typically comes from segment_characters but also any other segmentation operators can be used.

The process of the selection can be partitioned into four parts. All steps are influenced by the parameters StrokeWidth, CharHeight, and CharWidth. If you loose small objects like dots, adapt the minimum CharWidth and the minimum CharHeight. But some parameters affect the result of a certain step in particular. A closer description follows below. With the parameter StopAfter you can terminate after a specified step.

In the first step, 'step1_select_candidates', CharWidth and the CharHeight are used to select the candidates. The result of this step is also affected by ClutterSizeMax.

In the next step, 'step2_partition_characters', the parameter PartitionMethod and the parameter PartitionLines influence the result.

Step three, 'step3_connect_fragments', uses the parameters ConnectFragments and DotPrint. If dot-printed characters have to be detected and some dots are not connected to the character, there are two ways to overcome this problem: You can increase the FragmentDistance and/or decrease the StrokeWidth.

In the last step, 'step4_select_characters', the result is affected by the parameters DiacriticMarks and Punctuation.

DotPrint: Should be set to 'true' if dot prints should be read, else to 'false'.

StrokeWidth: Specifies the stroke width of the text. It is used to calculate internally used mask sizes to determine the characters. This mask sizes are also influenced through the parameters DotPrint, the average CharWidth, and the average CharHeight.

CharWidth: This can be a tuple with up to three values. The first value is the average width of a character. The second is the minimum width of a character and the third is the maximum width of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on average CharWidth. The same is the case if the maximum is not set. Some examples:

[10] sets the average character width to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character width to 10, the minimum value is calculated by the system, and the maximum is set to 20.

[10,5,20] sets the average character width to 10, the minimum to 5, and the maximum to 20.

CharHeight: This can be a tuple with up to three values. The first value is the average height of a character. The second is the minimum height of a character and the third is the maximum height of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on average CharHeight. The same is the case if the maximum is not set. Some examples:

[10] sets the average character height to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character height to 10 the minimum value is calculated by the system and the maximum is set to 20.

[10,5,20] this sets the average character height to 10, the minimum to 5 and the maximum to 20.

Punctuation: Set this parameter to 'true' if the operator also has to detect punctuation marks (e.g. .,:""), otherwise they will be suppressed.

DiacriticMarks: Set this parameter to 'true' if the text in your application contains diacritic marks (e.g. â,é,ö), or to 'false' to suppress them.

PartitionMethod: If neighboring characters are printed close to each other, they may be partly merged. With this parameter you can specify the method to partition such characters. The possible values are 'none', which means no partitioning is performed. 'fixed_width' means that the partitioning assumes a constant character width. If the width of the extracted region is well above the average CharWidth, the region ist split into parts that have the given average CharWidth. The partitioning starts at the left border of the region. 'variable_width' means that the characters are partitioned at the position where they have the thinnest connection. This method can be selected for characters that are printed with a variable-width font or if many consecutive characters are extracted as one symbol. It could be helpful to call text_line_slant and/or use text_line_orientation before calling select_characters.

PartitionLines: If some text lines or some characters of different text lines are connected, set this parameter to 'true'.

**FragmentDistance**: This parameter influences the connection of character fragments. If too much is connected, set the parameter to 'narrow' or 'medium'. In the case that more fragments should be connected, set the parameter to 'medium' or 'wide'. The connection is also influenced by the maximum of CharWidth and CharHeight. See also *ConnectFragments*.

**ConnectFragments**: Set this parameter to 'true' if the extracted symbols are fragmented, i.e., if a symbol is not extracted as one region but broken up into several parts. See also *FragmentDistance* and *StopAfter* in the step 'step3_connect_fragments'.

**ClutterSizeMax**: If the extracted characters contain clutter, i.e., small regions near the actual symbols, increase this value. If parts of the symbols are missing, decrease this value.

**StopAfter**: Use this parameter in the case the operator does not produce the desired results. By modifying this value the operator stops after the execution of the selected step and provides the corresponding results. To end on completion, set *StopAfter* to 'completion'.

---

**Parameters**

- **Region** (input_object) \( \rightarrow \text{object} \)
  Region of text lines in which to select the characters.

- **RegionCharacters** (output_object) \( \rightarrow \text{object} \)
  Selected characters.

- **DotPrint** (input_control) \( \rightarrow \text{string} \)
  Should dot print characters be detected?
  Default value: 'false'
  List of values: DotPrint \( \in \) {'true', 'false'}

- **StrokeWidth** (input_control) \( \rightarrow \text{string} \)
  Stroke width of a character.
  Default value: 'medium'
  List of values: StrokeWidth \( \in \) {'ultra_light', 'light', 'medium', 'bold'}

- **CharWidth** (input_control) \( \rightarrow \text{integer-array} \)
  Width of a character.
  Default value: 25
  Typical range of values: \( 1 \leq \text{CharWidth} \)
  Restriction: \( \text{CharWidth} \geq 1 \)

- **CharHeight** (input_control) \( \rightarrow \text{integer-array} \)
  Height of a character.
  Default value: 25
  Typical range of values: \( 1 \leq \text{CharHeight} \)
  Restriction: \( \text{CharHeight} \geq 1 \)

- **Punctuation** (input_control) \( \rightarrow \text{string} \)
  Add punctuation?
  Default value: 'false'
  List of values: Punctuation \( \in \) {'true', 'false'}

- **DiacriticMarks** (input_control) \( \rightarrow \text{string} \)
  Exist diacritic marks?
  Default value: 'false'
  List of values: DiacriticMarks \( \in \) {'true', 'false'}

- **PartitionMethod** (input_control) \( \rightarrow \text{string} \)
  Method to partition neighbored characters.
  Default value: 'none'
  List of values: PartitionMethod \( \in \) {'none', 'fixed_width', 'variable_width'}

- **PartitionLines** (input_control) \( \rightarrow \text{string} \)
  Should lines be partitioned?
  Default value: 'false'
  List of values: PartitionLines \( \in \) {'true', 'false'}

- **FragmentDistance** (input_control) \( \rightarrow \text{string} \)
  Distance of fragments.
  Default value: 'medium'
  List of values: FragmentDistance \( \in \) {'narrow', 'medium', 'wide'}
**ConnectFragments** (input_control) ........................................................ string  ~ string
Connect fragments?
Default value: 'false'
List of values: ConnectFragments ∈ {'true', 'false'}

**ClutterSizeMax** (input_control) ......................................................... integer  ~ integer
Maximum size of clutter.
Default value: 0
Typical range of values: 0 ≤ ClutterSizeMax
Restriction: 0 < ClutterSizeMax

**StopAfter** (input_control) ............................................................... string  ~ string
Stop execution after this step.
Default value: 'completion'
List of values: StopAfter ∈ {'step1_select_candidates', 'step2_partition_characters', 'step3_connect_fragments', 'step4_select_characters', 'completion'}

--- Example ---

for Index := 1 to 5 by 1
  read_image (Image, 'dot_print_rotated/dot_print_rotated_' + Index$'02d')
  text_line_orientation (Image, Image, 50, rad(-30), rad(30), OrientationAngle)
  rotate_image (Image, ImageRotate, deg(-OrientationAngle), 'constant')
  segment_characters (ImageRotate, ImageRotate, ImageForeground, 
                      RegionForeground, 'local_auto_shape', 'false', 'false', 'medium', 25, 25, 0, 10, UsedThreshold)
  select_characters (RegionForeground, RegionCharacters, 'true', 'ultra_light', 
                    [60,1,100], [60,1,100], 'false', 'false', 'none', 'true', 'wide', 'true', 0, 'completion')
endfor

--- Result ---

If the input parameters are set correctly, the operator select_characters returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

--- Module ---

**set_text_model_param** ( : : TextModel, GenParamName, GenParamValue : )

Set parameters of a text model.

set_text_model_param sets parameters of a text model. The list of allowed parameter values for GenParamName differs, depending on which Mode was set when creating the text model with create_text_model_reader. In the following, first the parameter values for text models with Mode = 'auto' are listed, and then those for text models with Mode = 'manual'.

The name and value of a parameter must be given in GenParamName and GenParamValue. The following values are possible:

- **Parameters of text models with Mode = 'auto’**
  
  - **Segmentation behavior**
    
    - `min_contrast': The minimal contrast the characters have to their surrounding background.
      
      List of values: integer or float value between 1 and 255 for byte images and between 1 and 65.535 for uint2 images
      
      Default value: 15
    
    - `polarity': 'dark_on_light’ if the text to be segmented is darker than its background, 'light_on_dark’ if the text to be segmented is lighter than its background, and 'both’ if both kinds of text are to be segmented.
      
      List of values: 'dark_on_light’, 'light_on_dark’, 'both’
      
      Default value: 'both’
    
    - `eliminate_border_blobs’: 'true’ if regions that are touching the border of the image domain should be discarded, otherwise 'false’.
      
      List of values: 'true’, 'false’
      
      Default value: 'false’
    
    - `add_fragments’: 'true’ if fragments, such as the dot on the 'i’, should be added to the segmented characters, otherwise 'false’. Be aware, that this can cause noise to be added to the segmented characters.
      
      List of values: 'true’, 'false’
      
      Default value: 'true’
    
    - `separate_touching_chars’: Controls the handling of pairs or small groups of neighboring characters that are segmented as one single region. When selecting 'standard’ or 'enhanced’, such regions are detected and separated into two or more single characters. While the 'enhanced’ method yields more accurate results, the 'standard’ method is less complex and thus faster. If 'separate_touching_chars’ is set to 'false’, no separation of touching characters is performed.
      
      Remark: If 'enhanced’ is selected, the file find_text_support.hotc from the ocr subdirectory of the root directory of the HALCON installation is needed. It is also possible to place this file in the current working directory.
      
      List of values: 'false’, 'standard’, 'enhanced’
      
      Default value: 'standard’

  - **Character size**
    
    - `min_char_height’: The minimal height of the characters in pixel. If text of arbitrary height is to be segmented, 'auto’ may be passed. Note that 'min_char_height’ refers to characters only. The height of punctuation marks or separators is not restricted by 'min_char_height’.
      
      List of values: integer or float value greater or equal to 1
      
      Default value: 'auto’
    
    - `max_char_height’: The maximal height of the characters in pixel. If text of arbitrary height is to be segmented, 'auto’ may be passed. Note that 'max_char_height’ refers to characters only. The height of punctuation marks or separators is not restricted by 'max_char_height’.
      
      List of values: integer or float value greater or equal to 1
      
      Default value: 'auto’
    
    - `min_char_width’: The minimal width of the characters in pixel. If text of arbitrary width is to be segmented, 'auto’ may be passed. Note that 'min_char_width’ refers to characters only. The width of punctuation marks or separators is not restricted by 'min_char_width’.
      
      List of values: integer or float value greater or equal to 1
      
      Default value: 'auto’
    
    - `max_char_width’: The maximal width of the characters in pixel. If text of arbitrary width is to be segmented, 'auto’ may be passed. Note that 'max_char_width’ refers to characters only. The width of punctuation marks or separators is not restricted by 'max_char_width’.
      
      List of values: integer or float value greater or equal to 1
      
      Default value: 'auto’
    
    - `min_stroke_width’: The minimal stroke width of the characters in pixel. If the minimal stroke width is to be estimated within the text segmentation process automatically, 'auto’ may be passed. Note that 'min_stroke_width’ refers to characters only. The stroke width of punctuation marks or separators is not restricted by 'min_stroke_width’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

‘max_stroke_width’: The maximal stroke width of the characters in pixel. If the maximal stroke width is to be estimated within the text segmentation process automatically, ‘auto’ may be passed. Note that ‘max_stroke_width’ refers to characters only. The stroke width of punctuation marks or separators is not restricted by ‘max_stroke_width’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

– Special characters

‘return_punctuation’: ‘true’ if small punctuation marks that lie close to the base line of the corresponding text line (e.g. dots or commas) are to be returned. ‘false’ if no such punctuations should be returned.
List of values: ‘true’, ‘false’
Default value: ‘true’

‘return_separators’: ‘true’ if separators such as a minus or the equality sign should be returned as well. ‘false’ if no separators should be returned.
List of values: ‘true’, ‘false’
Default value: ‘true’

– Handling of dot prints

‘dot_print’: ‘true’ if the text to be segmented contains dot printed characters, otherwise ‘false’.
List of values: ‘true’, ‘false’
Default value: ‘false’

‘dot_print_tight_char_spacing’: ‘true’ if the gap between adjacent characters is smaller than the largest gap between two dots within a single character, otherwise ‘false’. If ‘dot_print’ is set to ‘false’ this parameter does not have any effect. In cases where the minimal gap size between characters is exactly known, ‘dot_print_min_char_gap’ can be set instead. In this case the value of ‘dot_print_tight_char_spacing’ is ignored.
List of values: ‘true’, ‘false’
Default value: ‘false’

‘dot_print_min_char_gap’: The minimal gap size between two characters in pixel. This parameter can be used to improve the text result in cases where the minimal gap size between characters is smaller than the maximal gap size between dots within characters. If the minimal character gap size is not known or is bigger than the maximal dot gap size, ‘auto’ may be passed. If ‘dot_print’ is set to ‘false’ this parameter does not have any effect. In cases where the minimal gap size between characters is not known but the characters are printed close to each other, ‘dot_print_tight_char_spacing’ might be used instead.

Here, the minimal gap size between characters is 8 pixel.
List of values: integer or float value greater or equal to 0
Default value: ‘auto’

‘dot_print_max_dot_gap’: The maximal gap size between two dots within a character in pixel. If arbitrary dot printed characters are to be segmented, ‘auto’ may be passed. If ‘dot_print’ is set to ‘false’ this parameter does not have any effect. In cases where the maximal dot gap size is larger than or equal to the minimal gap size between characters, ‘dot_print_tight_char_spacing’ or ‘dot_print_min_char_gap’ should be set accordingly. Setting ‘dot_print_max_dot_gap’ can reduce the runtime of find_text significantly.
Here, the maximal gap size between dots is 3 pixel.

List of values: integer or float value greater or equal to 1
Default value: 'auto'

- **Line structures**

  'text_line_structure': To simplify the search for specific structures (e.g., dates or serial numbers) within the segmented text, it is possible to define text line structures. For each text line the distances between the characters are calculated, and based on these distances, the text line is divided into text blocks. Short characters such as '\.', '_' and '-' are ignored in this process and treated as spaces. Furthermore, it is possible to define user specific separators which are also ignored. See the description of 'text_line_separators' for details. It is then tested if any of the user defined text line structures fit the resulting text blocks.

  For example, if the text to be found is a date with two characters for month, day, and year the structure would be '2 2 2'. If the year may consist of two or four characters, the structure would be '2 2 2-4', indicating that the last character block consists of two to four characters. It is possible to provide more than one structure to match by appending an index to the parameter name, e.g. 'text_line_structure_0', 'text_line_structure_1'. If 'text_line_structure' is set to an empty string ' ', the text to be found may have any structure.

  Please observe, that every text line structure which is found, is saved as a unique text line within the text result. Hence, when calling get_text_object, a 'line' then refers to a valid text line structure. If the whole text line containing the text line structure is to be returned instead, it is possible to set 'return_whole_line' accordingly.

  Default value: ' '

  'text_line_separators': A string containing the list of characters which are to be ignored in the process of finding text line structures, see 'text_line_structure' for further details. Please note, user specific separators need to be valid characters within the used OCR classifier. For example, if ':' and '
' are to be ignored, ':\n' should be passed. Please observe, that '\n' escapes any special symbol to treat it as a literal, and hence '\n' needs to be passed to use '\n' as a separator.

  List of values: '/', ':', ':\', ':\/:', ....

  Default value: ' '

  'return_whole_line': 'false' if only the segmented text line structures are to be returned as text lines.
  'true' if each whole text line containing a text line structure is to be returned in text lines.

  List of values: 'true', 'false'

  Default value: 'false'

- **OCR classifier**

  'ocr_classifier': The OCR classifier used within find_text for text segmentation and classification.

  An initial classifier is set when the text model is created. See create_text_model_reader for more information about the required OCR Classifier.

  'num_classes': The number of best classes to be stored for each character. (E.g. if 'num_classes' is set to 2, find_text returns the classification results with the highest and second highest confidence). If 'num_classes' exceeds the number of classes of the classifier stored in the text model, 'num_classes' is decreased accordingly. The actual number of classes can be queried by get_text_result. For classifiers with rejection class, 'num_classes' should be at least 2 in order to be able to use the second best result if a character is classified as rejection class.

  List of values: integer greater than or equal to 1

  Default value: 2

- Parameters of text models with Mode = 'manual'

HALCON 20.05.0.0
'\texttt{manual\_char\_height}': Height of the characters in pixel. Refers to an uppercase character. Default value: 30px

'\texttt{manual\_char\_width}': Width of the characters in pixel. Refers to an uppercase character. Default value: 20px

'\texttt{manual\_stroke\_width}': Stroke width of the characters in pixel. Default value: 4.0px

'\texttt{manual\_base\_line\_tolerance}': Maximum base line deviation of the characters (in percent of '\texttt{manual\_char\_height}'). Default value: 0.15

'\texttt{manual\_polarity}': 'dark\_on\_light' if the text to be segmented is darker than its background, otherwise 'light\_on\_dark'. Default value: 'dark\_on\_light'

'\texttt{manual\_uppercase\_only}': 'true' if the text to be segmented contains uppercase characters or numbers only, otherwise 'false'. Default value: 'false'

'\texttt{manual\_is\_dotprint}': 'true' if the text to be segmented is a dotprint, otherwise 'false'. Default value: 'false'

'\texttt{manual\_is\_imprinted}': 'true' if the text to be segmented suffers of local changes of polarity due to reflections, otherwise 'false'. Default value: 'false'

'\texttt{manual\_eliminate\_horizontal\_lines}': 'true' if there are longer horizontal structures close to the text to be segmented, otherwise 'false'. Default value: 'false'

'\texttt{manual\_eliminate\_border\_blobs}': 'true' if regions that are touching the border of the image domain should be discarded, otherwise 'false'. Default value: 'false'

'\texttt{manual\_max\_line\_num}': Maximum number of lines to be found. Zero or negative values indicate no limitation. Setting '\texttt{manual\_max\_line\_num}' to a low value may strongly improve the runtime of \texttt{find\_text}. Default value: no limitation

'\texttt{manual\_return\_punctuation}': 'true' if punctuation marks (e.g., dots or comma) should be added to the segmented characters. Default value: 'true'

'\texttt{manual\_return\_separators}': 'true' if separators such as a minus or the equality sign should be added to the segmented characters. Default value: 'true'

'\texttt{manual\_add\_fragments}': 'true' if fragments, such as the dot on the 'i', should be added to the segmented characters. Be aware, that this can cause noise to be added to the segmented characters. Default value: 'true'

'\texttt{manual\_fragment\_size\_min}': minimum area of fragment regions that are added if '\texttt{manual\_add\_fragments}' is set to 'true'. Default value: 1

'\texttt{manual\_text\_line\_structure}': specifies the structure of the text to be found to reduce the search space and to avoid false positives. The structure is a string that contains the number of characters for every character block and spaces between these character blocks. For example, if the text to be found is a date with two characters for month, day, and year the structure would be '2 2 2'. If the year may also consist of four characters the structure would be '2 2 2-4', indicating that the last character block consists of two to four characters. It is possible to provide more than one structure to match by appending an index to the parameter name, e.g. '\texttt{manual\_text\_line\_structure\_0}', '\texttt{manual\_text\_line\_structure\_1}'. If '\texttt{manual\_text\_line\_structure}' is set to an empty string '', the text to be found may have any structure. Default value: ''

'\texttt{manual\_persistence}': 'true' if selected intermediate results should be kept with the output result of \texttt{find\_text}.

---

\texttt{TextModel} (input\_control) .................................................. text\_model \rightarrow handle

\texttt{GenParamName} (input\_control) ............................................. string(-array) \rightarrow string

\texttt{Names of the parameters to be set.}

\texttt{Default value: 'min\_contrast'}

\texttt{Suggested values: GenParamName \in \{ 'add\_fragments', 'dot\_print', 'dot\_print\_max\_dot\_gap', 'dot\_print\_min\_char\_gap', 'dot\_print\_tight\_char\_spacing', 'eliminate\_border\_blobs', 'max\_char\_height', 'max\_char\_width', 'max\_stroke\_width', 'min\_char\_height', 'min\_char\_width', 'min\_contrast', 'min\_stroke\_width', 'num\_classes', 'ocr\_classifier', 'polarity', 'return\_punctuation', 'return\_separators', 'return\_whole\_line', 'separate\_touching\_chars', 'text\_line\_separators', 'text\_line\_structure', 'text\_line\_structure\_0', 'text\_line\_structure\_1', 'text\_line\_structure\_2', 'manual\_add\_fragments', 'manual\_base\_line\_tolerance', 'manual\_char\_height', 'manual\_char\_width', 'manual\_eliminate\_border\_blobs', 'manual\_eliminate\_horizontal\_lines', 'manual\_fragment\_size\_min',...}
'manual_is_dotprint', 'manual_is_imprinted', 'manual_max_line_num', 'manual_persistence',
'manual_text_line_structure', 'manual_text_line_structure_0', 'manual_text_line_structure_1',
'manual_text_line_structure_2', 'manual_uppercase_only'}

GenParamValue (input_control) ........................................string(-array) \sim integer / real / string
Values of the parameters to be set.
Default value: 10
Suggested values: GenParamValue \in \{ 'true', 'false', 'dark_on_light', 'light_on_dark', 'both', 'auto',
'standard', 'enhanced' \}

Example
read_image (Image, 'numbers_scale')
cREATE_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
  * Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
  * Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

Result
If the input parameters are set correctly, the operator set_text_model_param returns the value 2
(H_MSG_TRUE). Otherwise, an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:
- TextModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across
multiple threads.

get_text_result (TextResultID, 'class', Class)

Module
OCR/OCV

text_line_orientation ( Region, Image : : CharHeight,
  OrientationFrom, OrientationTo : OrientationAngle )

Determines the orientation of a text line or paragraph.
text_line_orientation determines the orientation of a single text line or a paragraph in relation to
the horizontal image axis. If the orientation of a single text line should be determined, the range for the
OrientationFrom and OrientationTo should be in the interval from -\pi/4 to \pi/4.

The parameter Region specifies the area of the image in which the text lines are located. The Region is only
used to reduce the working area. To determine the slant, the gray values inside that area are used. The text lines are
segmented by the operator text_line_orientation itself. If more than one region is passed, the numerical
values of the orientation angle are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

`CharHeight` specifies the approximately height of the existing text lines in the region `Region`. It’s assumed, that the text lines are darker than the background.

The search area can be restricted by the parameters `OrientationFrom` and `OrientationTo`, whereby also the runtime of the operator is influenced.

With the calculated angle `OrientationAngle` and operators like `affine_trans_image`, the region `Region` of the image `Image` can be rotated such, that the text lines lie horizontally in the image. This may simplify the character segmentation for OCR applications.

---

**Parameters**

- **Region** (input_object) : region(-array) ~ object
  Area of text lines.
- **Image** (input_object) : singlechannelimage ~ object : byte / uint2
  Input image.
- **CharHeight** (input_control) : integer ~ integer
  Height of the text lines.
  Default value: 25
  Typical range of values: `1 <= CharHeight <= 1`
  Restriction: `CharHeight >= 1`
- **OrientationFrom** (input_control) : angle.rad ~ real
  Minimum rotation of the text lines.
  Default value: `-0.523599`
  Typical range of values: `-3.141593 <= OrientationFrom <= 3.141593`
  Restriction: `-2 * pi <= OrientationFrom <= 2 * pi`
- **OrientationTo** (input_control) : angle.rad ~ real
  Maximum rotation of the text lines.
  Default value: `0.523599`
  Typical range of values: `-3.141593 <= OrientationTo <= 3.141593`
  Restriction: `OrientationTo <= OrientationFrom && OrientationTo < OrientationFrom + pi`
- **OrientationAngle** (output_control) : angle.rad(-array) ~ real
  Calculated rotation angle of the text lines.

---

**Example**

```plaintext
read_image(Image,'letters')
text_line_orientation(Image,Image,50,rad(-80),rad(80),OrientationAngle)
rotate_image(Image,ImageRotate,-OrientationAngle/rad(180)*180,'constant')
```

---

**Result**

If the input parameters are set correctly, the operator `text_line_orientation` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Successors**

- `rotate_image`, `affine_trans_image`, `affine_trans_image_size`

---

**Module**

`text_line_slant` ( Region, Image : : CharHeight, SlantFrom, SlantTo : SlantAngle )

Determines the slant of characters of a text line or paragraph.

text_line_slant determines the slant of a single text line or a paragraph.

The parameter Region specifies the area of the image in which the text lines are located. The Region is only used to reduce the working area. To determine the slant, the gray values inside that area are used. The text lines are segmented by the operator text_line_slant itself. If more than one region is passed, the numerical values of the orientation angle are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

CharHeight specifies the approximately high of the existing text lines in the region Region. It’s assumed, that the text lines are darker than the background.

The search area can be restricted by the parameters SlantFrom and SlantTo, whereby also the runtime of the operator is influenced.

With the calculated slant angle SlantAngle and operators for affine transformations, the slant can be removed from the characters. This may simplify the character separation for OCR applications. To work correctly all characters of a region should have nearly the same slant.

Parameters

- Region (input_object) region(-array) → object
  Area of text lines.
- Image (input_object) singlechannelimage → object: byte / uint2
  Input image.
- CharHeight (input_control) integer → integer
  Height of the text lines.
  Default value: 25
  Typical range of values: 1 ≤ CharHeight
- SlantFrom (input_control) angle.rad → real
  Minimum slant of the characters
  Default value: -0.523599
  Typical range of values: -0.785398 ≤ SlantFrom ≤ 0.785398
  Restriction: - pi / 4 <= SlantFrom && SlantFrom <= SlantTo
- SlantTo (input_control) angle.rad → real
  Maximum slant of the characters
  Default value: 0.523599
  Typical range of values: -0.785398 ≤ SlantTo ≤ 0.785398
  Restriction: - pi / 4 <= SlantTo && SlantTo <= pi / 4
- SlantAngle (output_control) angle.rad(-array) → real
  Calculated slant of the characters in the region

Example

```halcon
hom_mat2d_identity(HomMat2DIdentity)
read_image(Image,'dot_print_slanted')
* correct slant
text_line_slant(Image,Image,50,rad(-45),rad(45),SlantAngle)
hom_mat2d_slant(HomMat2DIdentity,-SlantAngle,'x',0,0,HomMat2DSlant)
affine_trans_image(Image,Image,HomMat2DSlant,'constant','true')
```

Result

If the input parameters are set correctly, the operator text_line_slant returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
21.6 Support Vector Machines

**clear_ocr_class_svm** ( : : OCRHandle : )

Clear an SVM-based OCR classifier.

clear_ocr_class_svm clears the OCR classifier given by OCRHandle and frees all memory required for the classifier. After calling clear_ocr_class_svm, the classifier can no longer be used. The handle OCRHandle becomes invalid.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCRHandle</td>
<td>Handle of the OCR classifier.</td>
</tr>
</tbody>
</table>

**Result**

If OCRHandle is valid the operator clear_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

create_ocr_class_svm, read_ocr_class_svm, write_ocr_class_svm, trainf_ocr_class_svm

**Module**

OCR/OCV

**create_ocr_class_svm** ( : : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, KernelType, KernelParam, Nu, Mode, Preprocessing, NumComponents : OCRHandle )

Create an OCR classifier using a support vector machine.

create_ocr_class_svm creates an OCR classifier that uses a support vector machine (SVM). The handle of the OCR classifier is returned in OCRHandle.

For a description on how an SVM works, see create_class_svm. create_ocr_class_svm creates an SVM for classification with the classification mode given by Mode. The length of the feature vector of the SVM (NumFeatures in create_class_svm) is determined from the features that are used for the OCR, which are passed in Features. The features are described below. The kernel is parametrized with KernelType, KernelParam and Nu like in create_class_svm. The number of classes of the SVM (NumClasses
in `create_class_svm`) is determined from the names of the characters to be used in the OCR, which are passed in `characters`. As described with `create_class_svm`, the parameters `preprocessing` and `num_components` can be used to specify a preprocessing of the data (i.e., the feature vectors). For the sake of numerical stability, `preprocessing` can typically be set to ‘normalization’. In order to speed up classification time, ‘principal_components’ or ‘canonical_variates’ can be used, as the number of input features can be significantly reduced without deterioration of the recognition rate.

The features to be used for the classification are determined by `features`. `features` can contain a tuple of feature names. Each of these feature names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., ‘pixel_invar’). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by `width_character` and `height_character`. The interpolation to be used for the transformation is determined by `interpolation`. It has the same meaning as in `affine_trans_image`. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, `interpolation = 'constant'` should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, for large sizes small segmentation errors will have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, thus the character is zoomed differently than the characters in the training set. In most applications, sizes between $6 \times 8$ and $10 \times 14$ should be used.

The parameter `features` can contain the following feature names for the classification of the characters.

- ‘default’ ‘ratio’ and ‘pixel_invar’ are selected.
- ‘pixel’ Gray values of the character (`width_character` x `height_character` features).
- ‘pixel_invar’ Gray values of the character with maximum scaling of the gray values (`width_character` x `height_character` features).
- ‘pixel_binary’ Region of the character as a binary image zoomed to a size of `width_character` x `height_character` features.
- ‘gradient_8dir’ Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a $5 \times 5$ grid are extracted from each channel. These samples are used as features (200 features).
- ‘projection_horizontal’ Horizontal projection of the gray values (see `gray_projections`, `height_character` features).
- ‘projection_horizontal_invar’ Maximally scaled horizontal projection of the gray values (`height_character` features).
- ‘projection_vertical’ Vertical projection of the gray values (see `gray_projections`, `width_character` features).
- ‘projection_vertical_invar’ Maximally scaled vertical projection of the gray values (`width_character` features).
- ‘ratio’ Aspect ratio of the character (see `height_width_ratio`, 1 feature).
- ‘anisometry’ Anisometry of the character (see `eccentricity`, 1 feature).
- ‘width’ Width of the character before scaling the character to the standard size (not scale-invariant, see `height_width_ratio`, 1 feature).
- ‘height’ Height of the character before scaling the character to the standard size (not scale-invariant, see `height_width_ratio`, 1 feature).
- ‘zoom_factor’ Difference in size between the character and the values of `width_character` and `height_character` (not scale-invariant, 1 feature).
- ‘foreground’ Fraction of pixels in the foreground (1 feature).
- ‘foreground_grid_9’ Fraction of pixels in the foreground in a $3 \times 3$ grid within the smallest enclosing rectangle of the character (9 features).
- ‘foreground_grid_16’ Fraction of pixels in the foreground in a $4 \times 4$ grid within the smallest enclosing rectangle of the character (16 features).
- ‘compactness’ Compactness of the character (see `compactness`, 1 feature).
- ‘convexity’ Convexity of the character (see `convexity`, 1 feature).
"moments_region_2nd_invar" Normalized 2nd moments of the character (see \texttt{moments_region_2nd_invar}, 3 features).

"moments_region_2nd_rel_invar" Normalized 2nd relative moments of the character (see \texttt{moments_region_2nd_rel_invar}, 2 features).

"moments_region_3rd_invar" Normalized 3rd moments of the character (see \texttt{moments_region_3rd_invar}, 4 features).

"moments_central" Normalized central moments of the character (see \texttt{moments_region_central}, 4 features).

"moments_gray_plane" Normalized gray value moments and the angle of the gray value plane (see \texttt{moments_gray_plane}, 4 features).

"phi" Orientation (angle) of the character (see \texttt{elliptic_axis}, 1 feature).

"num_connect" Number of connected components (see \texttt{connect_and_holes}, 1 feature).

"num_holes" Number of holes (see \texttt{connect_and_holes}, 1 feature).

"cooc" Values of the binary cooccurrence matrix (see \texttt{gen_cooc_matrix}, 12 features).

"num_runs" Number of runs in the region normalized by the height (1 feature).

"chord_histo" Frequency of the runs per row (not scale-invariant, \texttt{HeightCharacter} features).

After the classifier has been created, it is trained using \texttt{trainf_ocr_class_svm}. After this, the classifier can be saved using \texttt{write_ocr_class_svm}. Alternatively, the classifier can be used immediately after training to classify characters using \texttt{do_ocr_single_class_svm} or \texttt{do_ocr_multi_class_svm}.

A comparison of SVM and the multi-layer perceptron (MLP) (see \texttt{create_ocr_class_mlp}) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

---

### Parameters

\begin{itemize}
  \item \textbf{WidthCharacter} (input\_control) \hspace{1em} \texttt{integer} $\sim$ \texttt{integer}
    
    Width of the rectangle to which the gray values of the segmented character are zoomed.
    
    Default value: 8
    
    Suggested values: \texttt{WidthCharacter} $\in$ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20\}
    
    Typical range of values: $4 \leq \text{WidthCharacter} \leq 20$
  
  \item \textbf{HeightCharacter} (input\_control) \hspace{1em} \texttt{integer} $\sim$ \texttt{integer}
    
    Height of the rectangle to which the gray values of the segmented character are zoomed.
    
    Default value: 10
    
    Suggested values: \texttt{HeightCharacter} $\in$ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20\}
    
    Typical range of values: $4 \leq \text{HeightCharacter} \leq 20$
  
  \item \textbf{Interpolation} (input\_control) \hspace{1em} \texttt{string}\(-\text{array}\) $\sim$ \texttt{string}
    
    Interpolation mode for the zooming of the characters.
    
    Default value: 'constant'
    
    List of values: \texttt{Interpolation} $\in$ \{'nearest\_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'\}
  
  \item \textbf{Features} (input\_control) \hspace{1em} \texttt{string\(-\text{array}\)} $\sim$ \texttt{string}
    
    Features to be used for classification.
    
    Default value: 'default'
    
    List of values: \texttt{Features} $\in$ \{'default', 'pixel', 'pixel\_invar', 'pixel\_binary', 'gradient\_8dir',
      'projection\_horizontal', 'projection\_horizontal\_invar', 'projection\_vertical', 'projection\_vertical\_invar',
      'ratio', 'anisometry', 'width', 'height', 'zoom\_factor', 'foreground', 'foreground\_grid\_9',
      'foreground\_grid\_16', 'compactness', 'convexity', 'moments\_region\_2nd\_invar',
      'moments\_region\_2nd\_rel\_invar', 'moments\_region\_3rd\_invar', 'moments\_central', 'moments\_gray\_plane',
      'phi', 'num\_connect', 'num\_holes', 'cooc', 'num\_runs', 'chord\_histo'\}
  
  \item \textbf{Characters} (input\_control) \hspace{1em} \texttt{string\(-\text{array}\)} $\sim$ \texttt{string}
    
    All characters of the character set to be read.
    
    Default value: \{'0','1','2','3','4','5','6','7','8','9'\}
  
  \item \textbf{KernelType} (input\_control) \hspace{1em} \texttt{string}\ $\sim$ \texttt{string}
    
    The kernel type.
    
    Default value: 'rbf'
    
    List of values: \texttt{KernelType} $\in$ \{'linear', 'rbf', 'polynomial\_inhomogeneous', 'polynomial\_homogeneous'\}
\end{itemize}
21.6. SUPPORT VECTOR MACHINES

KernelParam (input_control) ...................................................... real \sim real
Additional parameter for the kernel function.
Default value: 0.02
Suggested values: KernelParam \in [0.01, 0.02, 0.05, 0.1, 0.5]

Nu (input_control) .............................................................. real \sim real
Regularization constant of the SVM.
Default value: 0.05
Suggested values: Nu \in \{0.0001, 0.001, 0.01, 0.05, 0.1, 0.2, 0.3\}
Restriction: Nu > 0.0 \&\& Nu < 1.0

Mode (input_control) ......................................................... string \sim string
The mode of the SVM.
Default value: 'one-versus-one'
List of values: Mode \in ['one-versus-all', 'one-versus-one']

Preprocessing (input_control) ............................................... string \sim string
Type of preprocessing used to transform the feature vectors.
Default value: 'normalization'
List of values: Preprocessing \in ['none', 'normalization', 'principal_components', 'canonical_variates']

NumComponents (input_control) ............................................. integer \sim integer
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = 'none' and
Preprocessing = 'normalization').
Default value: 10
Suggested values: NumComponents \in \{1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100\}
Restriction: NumComponents \geq 1

OCRHandle (output_control) .................................................... ocr_svm \sim handle
Handle of the OCR classifier.

--- Example ---

read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
   Classes := [Classes,gen_tuple_const(20,chr(ord('a')+J))]
endfor
Classes := [Classes,gen_tuple_const(20,'.')]
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, \'rbf', 0.01, 0.01, 'one-versus-all', \'principal_components', 10, OCRHandle)
trainf_ocr_class_svm (OCRHandle, 'letters.trf', 0.001, 'default')
* Re-classify the characters in the image.
do_ocr_multi_class_svm (Characters, Image, OCRHandle, Class)

--- Result ---
If the parameters are valid the operator create_ocr_class_svm returns the value 2 (H_MSG_TRUE). If
necessary, an exception is raised.

--- Parallelization ---

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
CLOSED-UNCLASSIFIED

• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Possible Predecessors

Alternatives

deserialize_ocr_class_svm

### Parameters

- **SerializedItemHandle** (input_control)  
  Handle of the serialized item.

- **OCRHandle** (output_control)  
  Handle of the OCR classifier.

### Result

If the parameters are valid, the operator deserialize_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Module

OCR/OCV

---

deserialize_ocr_class_svm ( : : SerializedItemHandle : OCRHandle )

Deserialize a serialized SVM-based OCR classifier.

deserialize_ocr_class_svm deserializes a SVM-based OCR classifier, that was serialized by serialize_ocr_class_svm (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

### Parameters

- **SerializedItemHandle** (input_control)  
  Handle of the serialized item.

- **OCRHandle** (output_control)  
  Handle of the OCR classifier.

### Result

If the parameters are valid, the operator deserialize_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Module

OCR/OCV

---

do_ocr_multi_class_svm ( Character, Image : : OCRHandle : Class )

Classify multiple characters with an SVM-based OCR classifier.
Do OCR Multi-Class SVM computes the best class for each of the characters given by the regions Character and the gray values Image with the SVM-based OCR classifier OCRHandle and returns the classes in Class. In contrast to do_ocr_single_class_svm, do_ocr_multi_class_svm can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_svm to classify single characters. However, do_ocr_multi_class_svm can only return the best class of each character. Before calling do_ocr_multi_class_svm, the classifier must be trained with trainf_ocr_class_svm.

Parameters

- **Character** (input_object) ... region(-array) \(\rightarrow\) object
  Characters to be recognized.
- **Image** (input_object) ... singlechannelimage \(\rightarrow\) object : byte / uint2
  Gray values of the characters.
- **OCRHandle** (input_control) ... ocr_svm \(\rightarrow\) handle
  Handle of the OCR classifier.
- **Class** (output_control) ... string(-array) \(\rightarrow\) string
  Result of classifying the characters with the SVM.

Result

If the parameters are valid the operator do_ocr_multi_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

create_ocr_class_svm, classify_class_svm

Module

OCR/OCV

do_ocr_single_class_svm ( Character, Image : : OCRHandle, Num : : Class )

Classify a single character with an SVM-based OCR classifier.

do_ocr_single_class_svm computes the best Num classes of the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class. Because multiple classes may be returned by do_ocr_single_class_svm, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_svm must be used. Before calling do_ocr_single_class_svm, the classifier must be trained with trainf_ocr_class_svm.

Parameters

- **Character** (input_object) ... region \(\rightarrow\) object
  Character to be recognized.
- **Image** (input_object) ... singlechannelimage \(\rightarrow\) object : byte / uint2
  Gray values of the character.
- **OCRHandle** (input_control) ... ocr_svm \(\rightarrow\) handle
  Handle of the OCR classifier.
![Image of document page]

**Num** (input_control) .................................................. integer-array \(\sim\) integer

Number of best classes to determine.

**Default value:** 1

**Suggested values:** Num \(\in\) \{1, 2, 3, 4, 5\}

**Class** (output_control) .................................................. string(-array) \(\sim\) string

Result of classifying the character with the SVM.

---

If the parameters are valid the operator `do_ocr_single_class_svm` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Parallelization**

**Module**

OCR/OCV

---

```c
do_ocr_word_svm ( Character, Image : : OCRHandle, Expression, NumAlternatives, NumCorrections : Class, Word, Score )
```

Classify a related group of characters with an OCR classifier.

`do_ocr_word_svm` works like `do_ocr_multi_class_svm` insofar as it computes the best class for each of the characters given by the regions `Character` and the gray values `Image` with the OCR classifier `OCRHandle`, and returns the results in `Class`.

In contrast to `do_ocr_multi_class_svm`, `do_ocr_word_svm` treats the group of characters as an entity which yields a `Word` by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an `Expression` describing the expected word.

The `Expression` may restrict the word to belong to a predefined lexicon created using `create_lexicon` or `import_lexicon`, by specifying the name of the lexicon in angular brackets as in `<mylexicon>`. If the `Expression` is of any other form, it is interpreted as a regular expression with the same syntax as specified for `tuple_regexp_match`. Note that you will usually want to use an expression of the form "^...$" when using variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to `tuple_regexp_match`, `do_ocr_word_svm` does not support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the `Expression`, `do_ocr_word_svm` attempts to correct it by considering the `NumAlternatives` best classes for each character. The alternatives used are identical to those returned by `do_ocr_single_class_svm` for a single character. It does so by testing all possible corrections for which the classification result is changed for at most `NumCorrections` character regions. Note that `NumAlternatives` and `NumCorrections` affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the `Expression` is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than `NumCorrections` edit operations for the correction (see `suggest_lexicon`).

The resulting word is graded by a `Score` between 0.0 (no correction found) and 1.0 (original word correct). The `Score` is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many better classes have been ignored in order to match the `Expression`. 

---

\[
\text{Score} = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\text{PenaltyCorrections} = \alpha \times \text{num_corr}
\]
\[
\text{PenaltyAlternatives} = \alpha \times \beta \times \text{num_alt}
\]

with \text{num_corr} being the actual number of applied corrections and \text{num_alt} the total number of discarded alternatives.

\[
\alpha = \frac{1}{\text{NumCorrections} + 1}
\]
\[
\beta = \frac{1}{\text{NumCorrections} \times (\text{NumAlternatives} - 1) + 2}
\]

---

### Parameters

- **Character** (input_object) region(-array) \(\sim\) object
  Characters to be recognized.

- **Image** (input_object) singlechannelimage \(\sim\) object : byte / uint2
  Gray values of the characters.

- **OCRHandle** (input_control) ocr_svm \(\sim\) handle
  Handle of the OCR classifier.

- **Expression** (input_control) string \(\sim\) string
  Expression describing the allowed word structure.

- **NumAlternatives** (input_control) integer \(\sim\) integer
  Number of classes per character considered for the internal word correction.
  **Default value:** 3
  **Suggested values:** \text{NumAlternatives} \(\in\) \{3, 4, 5\}
  **Typical range of values:** \(1 \leq\text{NumAlternatives}\)

- **NumCorrections** (input_control) integer \(\sim\) integer
  Maximum number of corrected characters.
  **Default value:** 2
  **Suggested values:** \text{NumCorrections} \(\in\) \{1, 2, 3, 4, 5\}
  **Typical range of values:** \(0 \leq\text{NumCorrections}\)

- **Class** (output_control) string(-array) \(\sim\) string
  Result of classifying the characters with the SVM.
  **Number of elements:** Class \(\equiv\) Character

- **Word** (output_control) string \(\sim\) string
  Word text after classification and correction.

- **Score** (output_control) real \(\sim\) real
  Measure of similarity between corrected word and uncorrected classification results.

---

### Complexity

The complexity of checking all possible corrections is of magnitude \(O((n \times a)^{\min(c,n)})\), where \(a\) is the number of alternatives, \(n\) is the number of character regions, and \(c\) is the number of allowed corrections. However, to guard against a near-infinite loop in case of large \(n\), \(c\) is internally clipped to 5, 3, or 1 if \(a \times n \geq 30, 60,\) or 90, respectively.

---

### Result

If the parameters are valid, the operator \text{do\_ocr\_word\_svm} returns the value 2 (H\_MSG\_TRUE). If necessary an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
get_features_ocr_class_svm (Character : : OCRHandle,
        Transform : Features )

Compute the features of a character.
get_features_ocr_class_svm computes the features of the character given by Character with the OCR classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_svm and do_ocr_multi_class_svm, the character is passed as a single image object. Hence, before calling get_features_ocr_class_svm, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_svm for the classifier should be applied (Transform = 'true') or whether the untransformed features should be returned (Transform = 'false'). get_features_ocr_class_svm can be used to inspect the features that are used for the classification.

Parameters

- **Character** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . singlechannelimage ~ object : byte / uint2
  Input character.
- **OCRHandle** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . ocr_svm ~ handle
  Handle of the OCR classifier.
- **Transform** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string ~ string
  Should the feature vector be transformed with the preprocessing?
  Default value: 'true'
  List of values: Transform ∈ ['true', 'false']
- **Features** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . real-array ~ real
  Feature vector of the character.

Result

If the parameters are valid the operator get_features_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- trainf_ocr_class_svm
- do_ocr_multi_class_svm
- create_ocr_class_svm

Module

OCR/OCV
Return the parameters of an OCR classifier.

get_params_ocr_class_svm returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_svm. This is particularly useful if the classifier was read with read_ocr_class_svm. The output of get_params_ocr_class_svm can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_svm.

Parameters

�回 OCRHandle (input_control) ocr_svm ^ handle Handle of the OCR classifier.
回升 WidthCharacter (output_control) integer Width of the rectangle to which the gray values of the segmented character are zoomed.
回升 HeightCharacter (output_control) integer Height of the rectangle to which the gray values of the segmented character are zoomed.
回升 Interpolation (output_control) string Interpolation mode for the zooming of the characters.
回升 Features (output_control) string(-array) Features to be used for classification.
回升 Characters (output_control) string-array Characters of the character set to be read.
回升 KernelType (output_control) string The kernel type.
回升 KernelParam (output_control) real Additional parameters for the kernel function.
回升 Nu (output_control) real Regularization constant of the SVM.
回升 Mode (output_control) string The mode of the SVM.
回升 Preprocessing (output_control) string Type of preprocessing used to transform the feature vectors.
回升 NumComponents (output_control) integer Preprocessing parameter: Number of transformed features (ignored for Preprocessing = 'none' and Preprocessing = 'normalization').

Result

If the parameters are valid the operator get_params_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

trainf_ocr_class_svm, get_params_class_svm

Module

OCR/OCV
Compute the information content of the preprocessed feature vectors of an SVM-based OCR classifier.

`get_prep_info_ocr_class_svm` computes the information content of the training vectors that have been transformed with the preprocessing given by `Preprocessing`. `Preprocessing` can be set to `principal_components` or `canonical_variates`. The OCR classifier `OCRHandle` must have been created with `create_ocr_class_svm`. The preprocessing methods are described with `create_class_svm`. The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (NumFeatures for `principal_components` and min(NumClasses - 1, NumFeatures) for `canonical_variates`, see `create_class_svm`), and is returned in `InformationCont` as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the nth component of `CumInformationCont`, i.e., `CumInformationCont` contains the sums of the first n elements of `InformationCont`. To use `get_prep_info_ocr_class_svm`, a sufficient number of samples must be stored in the training files given by `TrainingFile` (see `write_ocr_trainf`). `InformationCont` and `CumInformationCont` can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the total data. This can be decided easily from the first value of `CumInformationCont` that lies above x%. The number thus obtained can be used as the value for `NumComponents` in a new call to `create_ocr_class_svm`. The call to `get_prep_info_ocr_class_svm` already requires the creation of a classifier, and hence the setting of `NumComponents` in `create_ocr_class_svm` to an initial value. However, if `get_prep_info_ocr_class_svm` is called it is typically not known how many components are relevant, and hence how to set `NumComponents` in this call. Therefore, the following two-step approach should typically be used to select `NumComponents`: In a first step, a classifier with the maximum number for `NumComponents` is created (NumFeatures for `principal_components` and min(NumClasses - 1, NumFeatures) for `canonical_variates`). Then, the training samples are saved in a training file using `write_ocr_trainf`. Subsequently, `get_prep_info_ocr_class_svm` is used to determine the information content of the components, and with this `NumComponents`. After this, a new classifier with the desired number of components is created, and the classifier is trained with `trainf_ocr_class_svm`.

**Parameters**

- `OCRHandle` (input_control) `ocr_svm` ↷ `handle` Handle of the OCR classifier.

- `TrainingFile` (input_control) `filename.read(-array)` ↷ `string` Names of the training files.
  - Default value: `'ocr.trf'`
  - File extension: `.trf`, `.otr`

- `Preprocessing` (input_control) `string` ↷ `string` Type of preprocessing used to transform the feature vectors.
  - Default value: `principal_components`
  - List of values: `Preprocessing ∈ ['principal_components', 'canonical_variates']`

- `InformationCont` (output_control) `real-array` ↷ `real` Relative information content of the transformed feature vectors.

- `CumInformationCont` (output_control) `real-array` ↷ `real` Cumulative information content of the transformed feature vectors.

**Example**

* Create the initial OCR classifier.

```
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
ncreate_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, \n 'rbf', 0.01, 0.01, 'one-versus-one', \n 'principal_components', 81, OCRHandle)
```

* Get the information content of the transformed feature vectors.
get_prep_info_ocr_class_svm (OCRHandle, 'ocr.trf', 'principal_components', \    InformationCont, CumInformationCont)

* Determine the number of transformed components.
* NumComp = [...]

create_ocr_class_svm (0, 10, 'constant', 'default', CharacterNames, \    'rbf', 0.01, 0.01, 'one-versus-one', \    'principal_components', NumComp, OCRHandle)

* Create the final OCR classifier.

trainf_ocr_class_svm (OCRHandle, 'ocr.trf', 0.001, 'default')
write_ocr_class_svm (OCRHandle, 'ocr.osc')

Result
If the parameters are valid the operator get_prep_info_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

get_prep_info_ocr_class_svm may return the error 9211 (Matrix is not positive definite) if Preprocessing = 'canonical_variates' is used. This typically indicates that not enough training samples have been stored for each class.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors
clear_ocr_class_svm, create_ocr_class_svm

Module
OCR/OCV

get_support_vector_num_ocr_class_svm (\    : : OCRHandle : NumSupportVectors, NumSVPerSVM )

Return the number of support vectors of an OCR classifier.

get_support_vector_num_ocr_class_svm returns in NumSupportVectors the number of support vectors that are stored in the support vector machine (SVM) given by OCRHandle. get_support_vector_num_ocr_class_svm should be called before the labels of individual support vectors are read out with get_support_vector_ocr_class_svm, e.g., for visualizing which of the training data become a SV (see get_support_vector_ocr_class_svm). The number of SVs in each classifier is listed in NumSVPerSVM. The reason that its sum differs from the number obtained in NumSupportVectors is that SV evaluations are reused throughout different binary sub-SVMs.

Parameters

▶ OCRHandle (input_control) ... ocr_svm ~ handle
OCR handle.
▶ NumSupportVectors (output_control) ... integer ~ integer
Total number of support vectors.
▶ NumSVPerSVM (output_control) ... integer-array ~ integer
Number of SV of each sub-SVM.

Result
If the parameters are valid the operator get_sample_num_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.
Multithreading type: reentrant (runs in parallel with non-exclusive operators).
Multithreading scope: global (may be called from any thread).
Processed without parallelization.

create_ocr_class_svm
Module
OCR/OCV

get_support_vector_ocr_class_svm ( : : OCRHandle, IndexSupportVector : Index )

Return the index of a support vector from a trained OCR classifier that is based on support vector machines.
The operator get_support_vector_ocr_class_svm maps support vectors of a trained SVM-based OCR classifier (given in OCRHandle) to the original training data set. The index of the SV is specified with IndexSupportVector. The index is counted from 0, i.e., IndexSupportVector must be a number between 0 and IndexSupportVectors - 1, where IndexSupportVectors can be determined with get_support_vector_num_ocr_class_svm. The index of this SV in the training data is returned in Index. get_support_vector_ocr_class_svm can, for example, be used to visualize the support vectors. To do so, the train file that has been used to train the SVM must be read with read_ocr_trainf. The value returned in Index must be incremented by 1 and can then be used to select the support vectors with select_obj from the training characters. If more than one train file has been used in trainf_ocr_class_svm Index behaves as if all train files had been merged into one train file with concat_ocr_trainf.

Parameters

- **OCRHandle** (input_control) : ocr_svm ~ handle
  OCR handle.
- **IndexSupportVector** (input_control) : integer-array ~ integer
  Number of stored support vectors.
- **Index** (output_control) : real ~ real
  Index of the support vector in the training set.

Result
If the parameters are valid the operator get_support_vector_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module
OCR/OCV

read_ocr_class_svm ( : : FileName : OCRHandle )

Read a SVM-based OCR classifier from a file.
read_ocr_class_svm reads an OCR classifier that has been stored with write_ocr_class_svm. Since the training of an OCR classifier can consume a relatively long time, the classifier is typically trained in an offline process and written to a file with write_ocr_class_svm. In the online process the classifier is read with read_ocr_class_svm and subsequently used for classification with do_ocr_single_class_svm or do_ocr_multi_class_svm.

### Parameters

- **FileName** (input control) ............................................ filename.read ↼ string File name. File extension: .osc, .fnt
- **OCRHandle** (output control) ........................................ ocr_svm ↼ handle Handle of the OCR classifier.

### Result

If the parameters are valid the operator read_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Successors

do_ocr_single_class_svm, do_ocr_multi_class_svm

### Module

OCR/OCV

reduce_ocr_class_svm ( : : OCRHandle, Method, MinRemainingSV, MaxError : OCRHandleReduced )

Approximate a trained SVM-based OCR classifier by a reduced SVM.

reduce_ocr_class_svm reduces the classification time of an SVM based OCR classifier OCRHandle by returning a reduced copy of it in OCRHandleReduced. The parameters Method, MinRemainingSV and MaxError have the same meaning as in reduce_class_svm and are described there. Please note that classification time can also be significantly reduced with a preprocessing step in create_ocr_class_svm, which possibly introduces less errors.

### Parameters

- **OCRHandle** (input control) ........................................ ocr_svm ↼ handle Original handle of SVM-based OCR-classifier.
- **Method** (input control) ........................................... string ↼ string Type of postprocessing to reduce number of SVs. Default value: 'bottom_up'
  List of values: Method ∈ {'bottom_up'}
- **MinRemainingSV** (input control) ................................. integer ↼ integer Minimum number of remaining SVs. Default value: 2
  Suggested values: MinRemainingSV ∈ {2, 3, 4, 5, 7, 10, 15, 20, 30, 50}
  Restriction: MinRemainingSV ≥ 2
CHAPTER 21 OCR

- **MaxError** (input_control)  
  Maximum allowed error of reduction.
  **Default value:** 0.001  
  **Suggested values:** MaxError ∈ {0.0001, 0.0002, 0.0005, 0.001, 0.002, 0.005, 0.01, 0.02, 0.05}  
  **Restriction:** MaxError > 0.0

- **OCRHandleReduced** (output_control)  
  SVMHandle of reduced OCR classifier.

If the parameters are valid the operator `reduce_ocr_class_svm` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

- **Parallelization**
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

```plaintext
select_feature_set_trainf_svm ( : : TrainingFile, FeatureList,  
  SelectionMethod, Width, Height, GenParamName,  
  GenParamValue : OCRHandle, FeatureSet, Score )
```

Selects an optimal combination of features to classify OCR data.

`select_feature_set_trainf_svm` selects an optimal combination of features, to classify the data given in the training file `TrainingFile` with a Support Vector Machine (SVM), for details see `create_ocr_class_svm`.

Possible features are all OCR features listed and explained in `create_ocr_class_svm`. All candidates which should be tested can be specified in `FeatureList`. A subset of these features is returned as selected features in `FeatureSet`.

`select_feature_set_trainf_svm` is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator `select_feature_set_svm`.

The selection method `SelectionMethod` is either a greedy search 'greedy' (iteratively add the feature with highest gain) or the dynamically oscillating search 'greedy_oscillating' (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method 'greedy' is generally preferable, since it is faster. Only in cases when a large training set is available the method 'greedy_oscillating' might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in `Score`.

The parameters 'nu' and 'gamma' for the SVM that is used to classify can be set to 'auto' by using the parameters `GenParamName` and `GenParamValue`. If they are set to 'auto', the estimated optimal 'nu' and/or 'gamma' is estimated. The automatic estimation of 'nu' and 'gamma' can take a substantial amount of time (up to days, depending on the data set and the number of features). Alternatively, a certain value for both can be set the same
21.6. SUPPORT VECTOR MACHINES

way. An explanation of the parameters 'nu' and 'gamma' as the kernel parameter of the radial basis function (RBF) kernel can be found in `create_class_svm`.

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_trainf_svm` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

### Parameters

- **TrainingFile** (input_control) ................................. `filename.read(-array) ~ string`
  Names of the training files.
  Default value: ".
  File extension: `.trf`, `.otr`

- **FeatureList** (input_control) ................................. `string(-array) ~ string`
  List of features that should be considered for selection.
  Default value:
  ```
  ```

- **SelectionMethod** (input_control) ................................. `string`
  Method to perform the selection.
  Default value: 'greedy'
  List of values: `SelectionMethod` ∈ {"greedy", 'greedy_oscillating'}

- **Width** (input_control) ........................................ `integer` ...
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 15

- **Height** (input_control) ........................................ `integer` ...
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 16

- **GenParamName** (input_control) ................................. `string-array ~ string`
  Names of generic parameters to configure the selection process and the classifier.
  Default value: []
  List of values: `GenParamName` ∈ {'nu', 'gamma'}

- **GenParamValue** (input_control) ................................. `number-array ~ real / integer / string`
  Values of generic parameters to configure the selection process and the classifier.
  Default value: []
  Suggested values: `GenParamValue` ∈ {'auto', '0.1', '0.3'}

- **OCRHandle** (output_control) ................................. `ocr_svm ~ handle`
  Trained OCR-SVM Classifier.

- **FeatureSet** (output_control) ................................. `string-array ~ string`
  Selected feature set, contains only entries from `FeatureList`.

- **Score** (output_control) ........................................ `real-array ~ real`
  Achieved score using two-fold cross-validation.

### Result

If the parameters are valid, the operator `select_feature_set_trainf_svm` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

select_feature_set_trainf_svm_protected ( : : TrainingFile,
Password, FeatureList, SelectionMethod, Width, Height,
GenParamName, GenParamValue : OCRHandle, FeatureSet, Score )

Select an optimal combination of features to classify OCR data from a (protected) training file.

select_feature_set_trainf_svm_protected selects an optimal combination of features to classify the data given in the training files TrainingFile with a support vector machine (SVM). Its functionality corresponds to the functionality of select_feature_set_trainf_svm, with the addition that select_feature_set_trainf_svm_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator’s functionality see select_feature_set_trainf_svm. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_svm_protected may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

TrainingFile (input_control) .......................... filename.read(-array) ~ string
Names of the training files.
Default value:”
File extension: .trf, .otr

Password (input_control) ............................. string(-array) ~ string
Passwords for protected training files.

FeatureList (input_control) ........................... string(-array) ~ string
List of features that should be considered for selection.
```

Module

OCR/OCV

serialize_ocr_class_svm ( : : OCRHandle : SerializedItemHandle )

Serialize a SVM-based OCR classifier

serialize_ocr_class_svm serializes a SVM-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocr_class_svm is converted to a serialized item. The OCR classifier is defined by the handle
```
OCRHandle. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr_class_svm`.

--- Parameters ---

- **OCRHandle** (input_control) Handle of the OCR classifier.
- **SerializedItemHandle** (output_control) Handle of the serialized item.

--- Result ---

If the parameters are valid, the operator `serialize_ocr_class_svm` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

--- Parallelization ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Module ---

OCR/OCV

--- Train an OCR classifier. ---

`trainf_ocr_class_svm` trains the OCR classifier `OCRHandle` with the training characters stored in the OCR training files given by `TrainingFile`. The training files must have been created, e.g., using `write_ocr_trainf`, before calling `trainf_ocr_class_svm`. The parameters `Epsilon` and `TrainMode` have the same meaning as in `train_class_svm`. Please, note that training characters that have no corresponding class in the classifier `OCRHandle` are discarded.

--- Parameters ---

- **OCRHandle** (input_control) Handle of the OCR classifier.
- **TrainingFile** (input_control) Names of the training files.  
  Default value: 'ocr.trf'  
  File extension: .trf, .otr
- **Epsilon** (input_control) Stop parameter for training.  
  Default value: 0.001  
  Suggested values: Epsilon ∈ {0.00001, 0.0001, 0.001, 0.01, 0.1}
- **TrainMode** (input_control) Mode of training.  
  Default value: 'default'  
  List of values: TrainMode ∈ {'default', 'add_sv_to_train_set'}
21.6. SUPPORT VECTOR MACHINES

Example

* Train an OCR classifier
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, 
    'rbf', 0.01, 0.01, 'one-versus-one', 
    'normalization', 81, OCRHandle)
trainf_ocr_class_svm (OCRHandle, 'ocr.trf', 0.001, 'default')
write_ocr_class_svm (OCRHandle, 'ocr.osc')

Result

If the parameters are valid the operator trainf_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

trainf_ocr_class_svm may return the error 9211 (Matrix is not positive definite) if Preprocessing = 'canonical_variates' is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change Preprocessing to 'normalization'. Another solution can be to add more training samples.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

\begin{itemize}
\item OCR/OCV
\end{itemize}

\begin{itemize}
\item \textbf{write\_ocr\_class\_svm} ( : : OCRHandle, FileName : )
\end{itemize}

Write an OCR classifier to a file.
write_ocr_class_svm writes the OCR classifier OCRHandle to the file given by FileName. If a file extension is not specified in FileName, the default extension '.osc' is appended to FileName. write_ocr_class_svm is typically called after the classifier has been trained with trainf_ocr_class_svm. The classifier can be read with read_ocr_class_svm.

Parameters

- **OCRHandle** (input_control) : handle Handle of the OCR classifier.
- **FileName** (input_control) : string File name.
  File extension: .osc

Result

If the parameters are valid the operator write_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- trainf_ocr_class_svm

Possible Successors

- clear_ocr_class_svm

- create_ocr_class_svm, read_ocr_class_svm, write_class_svm, read_class_svm

Module

OCR/OCV

21.7 Training Files

append_ocr_trainf ( Character, Image : : Class, TrainingFile : )

Add characters to a training file.

The operator append_ocr_trainf serves to prepare the training with the operator trainf_ocr_class_mlp or trainf_ocr_class_svm. Hereby regions, representing characters, including their gray values (region and pixel) and the corresponding class name will be written into a file. An arbitrary number of regions within one image is supported. For each character (region) in Character the corresponding class name must be specified in Class. The gray values are passed via the parameter Image. In contrast to the operator write_ocr_trainf the characters are appended to an existing file using the same training file format as this file. If the file does not exist, a new file is generated. In this case, the file format can be chosen by the parameter 'ocr_trainf_version' of the operator set_system. If no file extension is specified in TrainingFile, the extension '.trf' is appended to the name.

Parameters

- **Character** (input_object) : object Characters to be trained.
- **Image** (input_object) : object singlechannelimage Gray values of the characters.
- **Class** (input_control) : string Class (name) of the characters.
- **TrainingFile** (input_control) : string Name of the training file.
  Default value: 'train_ocr'
  File extension: .trf, .otr
Example

```c
char name[128];
char class[128];

read_image(&Image,"character.tiff");
binary_threshold(Image,&Dark, 'otsu', 'dark', &UsedThreshold);
connection(Dark,&Character);
count_obj(Character,&num);
create_tuple(&Class,num);
open_window(0,0,-1,-1,0,",",&WindowHandle);
set_color(WindowHandle,"red");
for (i=0; i<num; i++) {
    select_obj(Character,&SingleCharacter,i);
    disp_region(SingleCharacter,WindowHandle);
    printf("class of character %d ?
",i);
    scanf("%s
",class);
    append_ocr_trainf(Character,Image,name,class);
}
```

Result

If the parameters are correct, the operator `append_ocr_trainf` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- threshold, connection, read_ocr_trainf

Possible Successors

- trainf_ocr_class_mlp, trainf_ocr_class_svm, write_ocr_trainf

Alternatives

- write_ocr_trainf, write_ocr_trainf_image

Module

**concat_ocr_trainf** ( : : SingleFiles, ComposedFile : )

Concat training files.

The operator `concat_ocr_trainf` stores all characters which are contained in the files `SingleFiles` into a new file with the name `ComposedFile`. The file format can be defined by the parameter `ocr_trainf_version` of the operator `set_system`. If no file extension is specified in `ComposedFile`, the extension `.trf` is appended to the file name. It is not possible to use any of the files in `SingleFiles` as the new file `ComposedFile`.

Parameters

- **SingleFiles** (input_control) .......................................................... filename.read(-array) ~ string
  Names of the single training files.
  Default value: ”
  File extension: .trf, .otr
- **ComposedFile** (input_control) ................................................... filename.write ~ string
  Name of the composed training file.
  Default value: ‘all_characters’
  File extension: .trf
If the parameters are correct, the operator `concat_ocr_trainf` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

### Module

OCR/OCV

---

### `protect_ocr_trainf`

```c
(: : TrainingFile, Password,
 TrainingFileProtected : )
```

**Protection of training data.**

Obtaining training data for an OCR classifier can be a complicated and time consuming activity. Thus, training data is valuable and there might be the necessity to protect its usage. The general idea is to prevent protected OCR training data from being reviewed or modified in any way and to ensure that its usage, e.g., training an OCR classifier, is restricted by a user password.

The approach in HALCON is to obtain OCR training data in the usual way, then write it to an unprotected OCR training file using, e.g., `write_ocr_trainf`, and afterwards create a new file containing the OCR training data protected with a user password. Protected training files can be used with a set of special operators that also require the correct password in order to be able to process the data, e.g., for training an OCR classifier.

It is important to keep in mind that data in a protected OCR training file cannot be reviewed or modified in any way, thus it is important to keep the original, unprotected, training data files.

Protected OCR training data can be used for training of multilayer perceptron (MLP) classifiers and support vector machine (SVM) classifiers.

`protect_ocr_trainf` protects the OCR training data contained in the file `TrainingFile` and writes it to the protected training data file `TrainingFileProtected`. The protection is done with the user password `Password`. The same password has to be used afterwards in order to use the protected OCR training data, e.g., by the operators `trainf_ocr_class_mlp_protected` or `read_ocr_trainf_names_protected`. Empty passwords (or passwords containing the empty string) are not allowed. If the number of passwords `Password` equals 1, then every output file `TrainingFileProtected` is protected with that password, otherwise the number of passwords has to be equal to the number of input and output files and the output file at position n is protected with the password at position n.

---

### Parameters

- **TrainingFile** (`input_control`) .................. filename.read ▼ string
  Names of the training files.
  Default value: 
  File extension: `.trf`, `.otr`

- **Password** (`input_control`) .................. string(-array) ▼ string
  Passwords for protecting the training files.

- **TrainingFile Protected** (`input_control`) .................. filename.write ▼ string
  Names of the protected training files.
  File extension: `.trf`

---

### Result

If the parameters are correct, the operator `protect_ocr_trainf` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.
Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

select_feature_set_trainf_mlp

Module

---

read_ocr_trainf ( : Characters : TrainingFile : CharacterNames )

Read training characters from files and convert to images.

read_ocr_trainf reads all characters from the specified file names and converts them into images. The default HALCON file extension for the OCR training file is `trf`. The domain is defined according to the foreground of the characters (as specified in write_ocr_trainf). The names of the characters are returned in CharacterNames. If more than one file name is given the files are processed in the order of the file names.

Parameters

- **Characters** (output_object) .................. image-array \( \sim \) object : byte / uint2
  Images read from file.
- **TrainingFile** (input_control) .................. filename.read(-array) \( \sim \) string
  Names of the training files.
  Default value: 
  File extension: .trf, .otr
- **CharacterNames** (output_control) .............. string-array \( \sim \) string
  Names of the read characters.

Result

If the parameter values are correct the operator read_ocr_trainf returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

---

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Alternatives
read_ocr_trainf_select

Module

OCR/OCV

read_ocr_trainf_names ( : : TrainingFile : CharacterNames, CharacterCount )

Query which characters are stored in a training file.
read_ocr_trainf_names extracts the names and frequency of all characters in the specified training files.

Parameters

▷ TrainingFile (input_control) ........................................ filename.read(-array) ⨈ string
   Names of the training files.
   Default value: ”
   File extension: .trf, .otr
▷ CharacterNames (output_control) ................................ string(-array) ⨈ string
   Names of the read characters.
▷ CharacterCount (output_control) ................................ integer(-array) ⨈ integer
   Number of characters.

Result

If the parameter values are correct the operator read_ocr_trainf_names returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

See also
trainf_ocr_class_svm, trainf_ocr_class_mlp
Module

OCR/OCV

read_ocr_trainf_names_protected ( : : TrainingFile, Password : CharacterNames, CharacterCount )

Query which characters are stored in a (protected) training file.
read_ocr_trainf_names_protected extracts the names and frequency of all characters in the specified training files. Its functionality corresponds to the functionality of read_ocr_trainf_names, with the addition that read_ocr_trainf_names_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator’s functionality see read_ocr_trainf_names. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Parameters

▷ TrainingFile (input_control) ........................................ filename.read(-array) ⨈ string
   Names of the training files.
   Default value: ”
   File extension: .trf, .otr
▷ Password (input_control) ........................................ string(-array) ⨈ string
   Passwords for protected training files.
▷ CharacterNames (output_control) ................................ string(-array) ⨈ string
   Names of the read characters.
If the parameter values are correct the operator `read_ocr_trainf_names_protected` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `protect_ocr_trainf`
- `read_ocr_trainf_names`
- **Module**

**read_ocr_trainf_select** ( : Characters : TrainingFile,
 _SearchNames : _FoundNames )

*Read training specific characters from files and convert to images.*

`read_ocr_trainf_select` reads the characters given in `SearchNames` from the specified files and converts them into images. It works similar to `read_ocr_trainf` but here the characters which are extracted can be specified.

**Parameters**

- **Characters** (output_object) ......................... image-array ~ object : byte / uint2
  Images read from file.
- **TrainingFile** (input_control) ....................... filename.read(-array) ~ string
  Names of the training files.
  Default value: ”
  File extension: .trf, .otr
- **SearchNames** (input_control) ...................... string(-array) ~ string
  Names of the characters to be extracted.
  Default value: ’0’
- **FoundNames** (output_control) ...................... string(-array) ~ string
  Names of the read characters.

**Result**

If the parameter values are correct the operator `read_ocr_trainf_select` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `write_ocr_trainf`

**Possible Successors**

- `disp_image, select_obj, zoom_image_size`

**Alternatives**

- `read_ocr_trainf`
**Module**

**write_ocr_trainf** ( Character, Image : : Class, TrainingFile : )

**Storing of training characters into a file.**

The operator `write_ocr_trainf` serves to prepare the training with the operators `trainf_ocr_class_mlp` or `trainf_ocr_class_svm`. Hereby regions, representing characters, including their gray values (region and pixel) and the corresponding class name will be written into a file. An arbitrary number of regions within one image is supported. For each character (region) in `Character` the corresponding class name must be specified in `Class`. The gray values are passed via the parameter `Image`. If no file extension is specified in `TrainingFile` the extension ".trf" is appended to the file name. The version of the file format used for writing data can be defined by the parameter 'ocr_trainf_version' of the operator `set_system`.

**Parameters**

- **Character** (input_object) ........................................... region(-array) ~ object
  Characters to be trained.
- **Image** (input_object) ........................................... singlechannelimage ~ object : byte / uint2
  Gray values of the characters.
- **Class** (input_control) ........................................... string(-array) ~ string
  Class (name) of the characters.
- **TrainingFile** (input_control) ................................... filename.write ~ string
  Name of the training file.
  Default value: 'train_ocr'
  File extension: .trf

**Result**

If the parameters are correct, the operator `write_ocr_trainf` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Successors**

`trainf_ocr_class_mlp, trainf_ocr_class_svm`

**Module**

**write_ocr_trainf_image** ( Character : : Class, TrainingFile : )

**Write characters into a training file.**

The operator `write_ocr_trainf_image` is used to prepare the training with the operators `trainf_ocr_class_mlp` or `trainf_ocr_class_svm`. Hereby regions, representing characters, including their gray values (region and pixel) and the corresponding class name will be written into a file. An arbitrary number of regions within one image is supported. For each character (region) in `Character` the corresponding class name must be specified in `Class`. If no file extension is specified in `TrainingFile` the extension ".trf" is appended to the file name. In contrast to `write_ocr_trainf` one image per character is passed. The domain of this image defines the pixels which belong to the character. The file format can be defined by the parameter 'ocr_trainf_version' of the operator `set_system`.
Parameters

- **Character** (input_object) \[\text{singlechannelimage(-array)} \Rightarrow \text{object} : \text{byte / uint2}
  Characters to be trained.

- **Class** (input_control) \[\text{string(-array)} \Rightarrow \text{string}
  Class (name) of the characters.

- **TrainingFile** (input_control) \[\text{filename.write} \Rightarrow \text{string}
  Name of the training file.
  Default value: 'train_ocr'
  File extension: .trf

Result

If the parameters are correct, the operator `write_ocr_trainf_image` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

OCR/OCV
Chapter 22
Object

This chapter contains operators that can be used to either query information related to iconic objects or to manipulate iconic objects.

Available Iconic Objects
HALCON provides different kinds of iconic objects that are suitable for different needs:

1. A region (2), an ROI that is created using the dilated boundary of the region (3), contours (4), polygons (5), and parallels (6) are extracted.

Images: An image consists of one to multiple channels, i.e., matrices of similar size that contain gray values of various pixel types. Images are the major source for most machine vision tasks.

Regions: A region is defined as a set of pixels. The pixels of a region do not need to be connected. This means that even an arbitrary collection of pixels can be handled as a single region. Region processing is suitable, e.g., to apply a blob analysis within images or to define a region of interest (ROI) for following subpixel-precise operations.

XLDs: XLD is the abbreviation for eXtended Line Description and comprises all contour and polygon based data. Note that XLD contours are returned or used by many HALCON operators whereas XLD polygons and XLD parallels are needed only in special cases. A contour is a sequence of subpixel-accurate 2D control points that are connected by lines. Typically, the distance between control points is about one pixel. XLD objects contain, besides the control points, so-called local and global attributes. Typical examples for these...
are, e.g., the edge amplitude of a control point or the regression parameters of a contour segment. Contour processing is suitable, e.g., for subpixel-precise measurements. Subpixel-precise operations can be faster if they are applied within an ROI.

Further Information

See the “Quick Guide” for further details about the available data structures.

22.1 Information

\[
\text{\texttt{\textbf{compare_obj}( Objects1, Objects2 : : Epsilon : IsEqual )}}
\]

\textit{Compare iconic objects regarding equality.}

The operator \texttt{compare_obj} compares iconic objects regarding equality. The iconic objects are passed in the two input parameters \texttt{Objects1} and \texttt{Objects2} in form of (possibly mixed) tuples of images, regions, or XLDs. The n-th object in \texttt{Objects1} is compared to the n-th object in \texttt{Objects2} (for all n). If the two passed object tuples have the same length and if all objects are equal, the parameter \texttt{IsEqual} is set to 1, otherwise to 0.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object. Depending on the type of the input objects, different conditions must be met for the equality of two objects. In the following, the conditions for each possible iconic object are listed:

\textbf{Images}: For all channels, the gray values of the respective pixels must not differ by more than \texttt{Epsilon}. Note that images are only compared within their domain (ROI) and they are only equal if they have the same domain (ROI).

\textbf{Regions}: The regions must be equal. The parameter \texttt{Epsilon} has no effect for the comparison of regions.

\textbf{XLD contours}: XLD contours must have the same number of points and attributes. The point coordinates and the attribute values must not differ by more than \texttt{Epsilon}.

\textbf{XLD polygons}: XLD polygons must have the same number of line segments. The length and the orientation of these segments as well as the coordinates of the control points must not differ by more than \texttt{Epsilon}.

\textbf{XLD parallels and extended XLD parallels}: XLD parallels must have an identical index of the start and end line segment of the parallels of the first polygon (P1) and the second polygon (P2) as well as identical pointers to the underlying contours.

\textbf{Modified XLD parallels}: For modified XLD parallels, the same conditions apply as for XLD parallels and extended XLD parallels. Furthermore, the distances between the line segments of the parallel polygons must be identical.

Note that \texttt{compare_obj} compares all objects regarding their actual content. In contrast \texttt{test_equal_obj} compares only regions regarding their actual content while for all other objects their location in memory is compared.

\begin{tabular}{ll}
\hline
\textbf{Parameters} & \\
\hline
\texttt{Objects1} & \texttt{object(-array)} \\
\texttt{Objects2} & \texttt{object(-array)} \\
\texttt{Epsilon} & \texttt{number \sim real / integer} \\
\textbf{Default value:} 0.0 & \\
\textbf{Suggested values:} Epsilon \in \{0.0, 1.e-5\} & \\
\texttt{IsEqual} & \texttt{integer \sim integer} \\
\hline
\end{tabular}

\textbf{Result} \\
The operator \texttt{compare_obj} returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input objects available) is set via the operator \texttt{set_system("no_object_result",<Result>)}. If the number of objects differs an exception is raised.
22.1. INFORMATION

---

**Parallelization**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also: `test_equal_obj`, `test_equal_region`

---

**count_obj ( Objects : : : Number )**

Number of objects in a tuple.

The operator `count_obj` determines for the object parameter `Objects` the number of objects it contains. In this connection it should be noted that object is not the same as connection component (see `connection`). For example, the number of objects of one region consisting of three parts that are not connected is 1.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter `Object`.

---

**Parameters**

- `Objects` (input_object) object-array `object`
  Objects to be examined.
- `Number` (output_control) integer `integer`
  Number of objects in the tuple `Objects`.

---

**Complexity**

Runtime complexity: \(O(|\text{Objects}|)\).

---

**Result**

`count_obj` returns the value 2 (H_MSG_TRUE).

---

**Parallelization**

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also: `copy_obj`, `obj_to_integer`, `connection`, `set_system`

---

**get_channel_info ( Object : : Request, Channel : : Information )**

Informations about the components of an image object.

The operator `get_channel_info` gives information about the components of an image object. The following requests (Request) are currently possible:

- `creator` Output of the names of the procedures which initially created the image components (not the object).

HALCON 20.05.0.0
In the tuple Channel the numbers of the components about which information is required are stated. After carrying out get_channel_info, Information contains a tuple of strings (one string per entry in Channel) with the required information.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

--- Parameters ---

▷ Object (input_object) ........... object
  Image object to be examined.

▷ Request (input_control) .......... string
  Required information about object components.
  Default value: 'creator'
  List of values: Request ∈ {'creator', 'type'}

▷ Channel (input_control) .......... channel(-array)
  Components to be examined (0 for region/XLD).
  Default value: 0
  Suggested values: Channel ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8}

▷ Information (output_control) .. string(-array)
  Requested information.

--- Result ---

If the parameters are correct the operator get_channel_info returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

--- Parallelization ---

• Supports objects on compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

--- Possible Predecessors ---

read_image

count_relation

--- See also ---

Foundation

--- Module ---

get_obj_class ( Object : : : Class )

Name of the class of an image object.

get_obj_class returns the name of the corresponding class to each object. The following classes are possible:

'object'  Object with region (definition domain) and at least one channel.
'region'  Object with a region without gray values.
'xld_cont' XLD object as contour
'xld_poly' XLD object as polygon
'xld_parallel' XLD object with parallel polygons

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.
Parameters

- **Object** (input_object) ...................................................... object(-array) ~ object
  Image objects to be examined.
- **Class** (output_control) ...................................................... string(-array) ~ string
  Name of class.

Result

If the parameter values are correct the operator `get_obj_class` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Parallelization

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors
disp_image, disp_region, disp_xld

See also
getchannel_info, count_relation

Module

**test_equal_obj** ( Objects1, Objects2 : : : IsEqual )

*Compare image objects regarding equality.*

The operator `test_equal_obj` compares the regions and gray value components of all objects of the two input parameters. The n-th object in `Objects1` is compared to the n-th object in `Objects2` (for all n). If all corresponding regions are equal and the number of regions is also identical the parameter `IsEqual` is set to TRUE, otherwise FALSE.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

Image matrices and XLDs are not compared regarding their contents. Thus, two images or XLDs, respectively, are “equal” if they are located at the same place in the storage. By contrast, regions that are not located at the same place in the storage are compared regarding their actual contents. If the input parameters are empty and the behavior was set via the operator `set_system(::'no_object_result','true':)` the parameter `IsEqual` is set to TRUE, since all input (= empty set) is equal.

Parameters

- **Objects1** (input_object) ...................................................... object-array ~ object
  Test objects.
- **Objects2** (input_object) ...................................................... object-array ~ object
  Comparative objects.
- **IsEqual** (output_control) ...................................................... integer ~ integer
  Boolean result value.

Complexity

If \( F \) is the area of a region the runtime complexity is \( O(1) \) or \( O(\sqrt{F}) \) if the result is TRUE and \( O(\sqrt{F}) \) if the result is FALSE.

Result

The operator `test_equal_obj` returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input objects available) is set via the operator `set_system(::'no_object_result','true':)<Result>). If the number of objects differs an exception is raised. Else `test_equal_obj` returns 2 (H_MSG_TRUE)
• Supports objects on compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

compare_obj, test_equal_region

Module
Foundation

22.2 Manipulation

clear_obj ( Objects : : : )

Delete an iconic object from the HALCON database.

clear_obj deletes iconic objects, which are no longer needed, from the HALCON database. It should be noted that clear_obj is the only way to delete objects from the database, and hence to reclaim their memory, in HALCON/C. In all other HALCON language interfaces, clear_obj must not be used because objects are destroyed automatically through appropriate destructors.

Images and regions are normally used by several iconic objects at the same time (uses less memory!). This has the consequence that a region or an image is only deleted if all objects using it have been deleted.

The operator reset_obj_db can be used to reset the system and clear all remaining iconic objects.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

Regarding the use of local variables in HALCON/C: When exiting a subroutine, the local variables are deleted, but the HALCON database is not updated. To update the database and thus free the memory, you must explicitly clear the local objects from the database before exiting the subroutine.

Parameters

▷ Objects (input_object) .................................................. object(-array) ~ object
Objects to be deleted.

Result

clear_obj returns 2 (H_MSG_TRUE) if all objects are contained in the HALCON database. If not all objects are valid (e.g., already cleared), an exception is raised, which also clears all valid objects. The operator set_check(::"clear") can be used to suppress the raising of this exception. If the input is empty the behavior can be set via set_system(::"no_object_result",<Result>). If necessary, an exception is raised.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Alternatives

reset_obj_db

set_check

Module
Foundation
22.2. MANIPULATION

**concat_obj** ( Objects1, Objects2 : ObjectsConcat : )

**Concatenate two iconic object tuples.**

`concat_obj` concatenates the two tuples of iconic objects `Objects1` and `Objects2` into a new tuple of iconic objects `ObjectsConcat`. Hence, this tuple contains all the iconic objects of the two input tuples:

```
ObjectsConcat = [Objects1,Objects2]
```

In `ObjectsConcat`, the objects of `Objects1` are stored first, followed by the objects of `Objects2`, i.e., the order of the objects is preserved. Note that only references to the corresponding images and regions are stored in `ObjectsConcat`, i.e., no new memory is allocated. Furthermore, this means that modifications of input images, e.g., with `set_grayval`, `overpaint_gray`, or `overpaint_region` directly affect the images of the output tuple `ObjectsConcat` and vice versa.

`concat_obj` should not be confused with `union1` or `union2`, in which regions are merged, i.e., in which the number of objects is modified.

`concat_obj` can be used to concatenate objects of different image object types (e.g., images and XLD contours) into a single object. This is only recommended if it is necessary to accumulate in a single object variable, for example, the results of an image processing sequence. It should be noted that the only operators that can handle such object tuples of mixed type are `concat_obj`, `copy_obj`, `select_obj`, and `disp_obj`.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter *Object*.

### Parameters

- **Objects1** (input_object) object(-array) \(\rightarrow\) object
  - Object tuple 1.
- **Objects2** (input_object) object(-array) \(\rightarrow\) object
  - Object tuple 2.
- **ObjectsConcat** (output_object) object-array \(\rightarrow\) object
  - Concatenated objects.

### Example

```c
/* generate a tuple of a circle and a rectangle */

gen_circle(&Circle,200.0,400.0,23.0);
gen_rectangle1(&Rectangle,23.0,44.0,203.0,201.0);
concat_obj(Circle,Rectangle,&CirclAndRectangle);
disp_region(CirclAndRectangle,WindowHandle);
```

### Complexity

Runtime complexity: \(O(|Objects1| + |Objects2|)\);  
Memory complexity of the result objects: \(O(|Objects1| + |Objects2|)\)

### Result

`concat_obj` returns 2 (H_MSG_TRUE) if all objects are contained in the HALCON database. If the input is empty the behavior can be set via `set_system(::'no_object_result',<Result>):`. If necessary, an exception is raised.

### Parallelization

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### See also

`count_obj`, `copy_obj`, `select_obj`, `disp_obj`

### Module

Foundation

```c
copy_obj ( Objects : ObjectsSelected : Index, NumObj : )
```

Copy an iconic object in the HALCON database.

`copy_obj` copies `NumObj` iconic objects beginning with index `Index` (starting with 1) from the iconic input object tuple `Objects` to the output object `ObjectsSelected`. If -1 is passed for `NumObj`, all objects beginning with `Index` are copied. No new storage is allocated for the regions and images. Instead, new objects containing references to the existing objects are created. The number of objects in an object tuple can be queried with the operator `count_obj`.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter `Object`.

**Parameters**

- **Objects** (input_object) .......... object(-array)  
  Objects to be copied.
- **ObjectsSelected** (output_object) .......... object(-array)  
  Copied objects.
- **Index** (input_control) .......... integer  
  Starting index of the objects to be copied.  
  Default value: 1  
  Suggested values: `Index ∈ {1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500, 1000, 2000, 5000}`  
  Typical range of values: `1 ≤ Index`  
  Restriction: `Index <= number(Objects)`
- **NumObj** (input_control) .......... integer  
  Number of objects to be copied or -1.  
  Default value: 1  
  Suggested values: `NumObj ∈ {-1, 1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500, 1000, 2000, 5000}`  
  Typical range of values: `-1 ≤ NumObj`  
  Restriction: `NumObj + Index - 1 <= number(Objects) && NumObj != 0`

**Example**

```c
gen_circle (Circles, [100,200,400], [200,100,400], [100,100,50])
copy_obj (Circles, CircleCopy, 2, 3)
erosion_circle (CircleCopy, CircleErosion, 15.5)
dev_set_color ('red')
dev_set_draw ('fill')
dev_display(Circles)
dev_set_color ('white')
dev_set_draw ('margin')
dev_display (CircleCopy)
dev_set_color ('green')
dev_display (CircleErosion)
```

**Complexity**

Runtime complexity: \(O(|\text{Objects}| + \text{NumObj})\);
Memory complexity of the result object: \(O(\text{NumObj})\)

**Result**

`copy_obj` returns 2 (H_MSG_TRUE) if all objects are contained in the HALCON database and all parameters are correct. If the input is empty the behavior can be set via `set_system(:: 'no_object_result',<Result>):`. If necessary, an exception is raised.

**Parallelization**

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

count_obj, concat_obj, obj_to_integer, copy_image

Module

Foundation

```
**gen_empty_obj** ( : EmptyObject : : )
```

Create an empty object tuple.

The operator **gen_empty_obj** creates an empty tuple. This means that the output parameter does not contain any objects. Thus, the operator **count_obj** returns 0. However, **clear_obj** can be called for the output. It should be noted that no objects must not be confused with an empty region. In case of an empty region, i.e. a region with 0 pixels **count_obj** returns the value 1.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter **Object**.

Parameters

- **EmptyObject** (output_object) .....................object ~ object
  No objects.

Parallelization

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
**insert_obj** ( Objects, ObjectsInsert : ObjectsExtended : Index : )
```

Insert objects into an iconic object tuple.

**insert_obj** inserts the elements of **ObjectsInsert** at **Index** into the object tuple **Objects** and returns the result in **ObjectsExtended**.

**Index** must contain a single integer value. Note that, in contrast to control tuples, indices of object tuple elements start at 1. The length of **ObjectsExtended** is the sum of the length of **Objects** and **ObjectsInsert**. It is allowed to mix images, regions and XLDs in **Objects** and **ObjectsInsert**.

Parameters

- **Objects** (input_object) ......................object(-array) ~ object
  Input object tuple.
- **ObjectsInsert** (input_object) ..........object(-array) ~ object
  Object tuple to insert.
- **ObjectsExtended** (output_object) ..........object(-array) ~ object
  Extended object tuple.
- **Index** (input_control) ......................number ~ integer
  Index to insert objects.

Example
gen_image_const (Image1, 'byte', 1, 1)
gen_image_const (Image3, 'byte', 3, 3)
concat_obj (Image1, Image3, Images)
gen_image_const (Image, 'byte', 2, 2)
insert_obj (Images, Image, Images, 2)

Complexity

Typical runtime complexity: $O(|\text{Objects}| + |\text{ObjectsInsert}|)$.

Parallelization

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

count_obj

Possible Successors

count_obj

Alternatives

concat_obj

count_obj, select_obj, copy_obj, remove_obj

Module

integer_to_obj ( : Objects : SurrogateTuple : )

Convert an “integer number” into an iconic object.

integer_to_obj is the inverse operator to obj_to_integer. All surrogates of objects passed in SurrogateTuple are stored as objects. In contrast to obj_to_integer, the objects are duplicated. integer_to_obj is intended especially for use in HALCON/C, because iconic objects and control parameters are treated differently in C. Please note that if you pass the value 0 in SurrogateTuple, the program will crash because 0 is no valid pointer.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

The objects are duplicated in the database.

Parameters

▷ Objects (output_object) ........................................... object(-array) $\rightsquigarrow$ object
Created objects.
▷ SurrogateTuple (input_control) ........................................... pointer(-array) $\rightsquigarrow$ integer
Tuple of object surrogates.

Result

integer_to_obj returns 2 (H_MSG_TRUE) if all parameters are correct, i.e., if they are valid object keys. If the input is empty the behavior can be set via set_system(:'no_object_result',<Result>:). If necessary, an exception is raised.

Parallelization

• Supports objects on compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
22.2. MANIPULATION

- Processed without parallelization.

Module

Foundation

---

**obj_diff ( Objects, ObjectsSub : ObjectsDiff : : )**

*Calculate the difference of two object tuples.*

**obj_diff** calculates the set-theoretic difference of two object tuples:

\[(\text{objects in } \text{Objects}) - (\text{objects in } \text{ObjectsSub})\]

The resulting object tuple **ObjectsDiff** is defined as the input tuple **Objects** with all objects from **ObjectsSub** removed.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

---

**Attention**

Image matrices and XLDs are not compared regarding their contents. Thus, two images or XLDs, respectively, are “equal” if they are located at the same place in the storage. By contrast, regions that are not located at the same place in the storage are compared regarding their actual contents.

---

**Parameters**

- **Objects** (input_object) .............. object(-array) → object
  - Object tuple 1.
- **ObjectsSub** (input_object) .............. object(-array) → object
  - Object tuple 2.
- **ObjectsDiff** (output_object) .............. object(-array) → object
  - Objects from **Objects** that are not part of **ObjectsSub**.

**Result**

**obj_diff** always returns 2 (H_MSG_TRUE).

---

**Parallelization**

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**obj_to_integer ( Objects : : Index, Number : SurrogateTuple )**

*Convert an iconic object into an “integer number.”*

**obj_to_integer** stores **Number**, starting at index **Index**, of the database keys of the input object **Objects** as integer numbers in the output parameter **SurrogateTuple**. If -1 is passed for **Number** all objects beginning with **Index** are copied. This facilitates a direct access to an arbitrary element of **Objects**. In conjunction with **count_obj** (returns the number of objects in **Objects**) the elements of **Objects** can be processed successively. The objects are not duplicated by **obj_to_integer** and thus must not be cleared by **clear_obj**.
For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

The objects’ data is not duplicated.

Parameters

- **Objects** *(input_object) → object*  
  Objects for which the surrogates are to be returned.

- **Index** *(input_control) → integer*  
  Starting index of the surrogates to be returned.
  
  **Default value:** 1
  
  **Typical range of values:** $1 \leq \text{Index}$

- **Number** *(input_control) → integer*  
  Number of surrogates to be returned.
  
  **Default value:** -1
  
  **Restriction:** Number == -1 || Number + Index <= number(Objects)

- **SurrogateTuple** *(output_control) → integer*  
  Tuple containing the surrogates.

Example

* Access the i-th element:
