Create an image with a rectangular domain from a pointer on the pixels (with storage management).

The operator `gen_image1_rect` creates an image of size \( \text{VerticalPitch} / (\text{HorizontalBitPitch} / 8) \) * Height. The pixels pointed to by `PixelPointer` are stored line by line. Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

`VerticalPitch` determines the distance (in bytes) between pixel \( m \) in row \( n \) and pixel \( m \) in row \( n+1 \) inside of memory. All rows of the ‘input image’ have the same vertical pitch. The width of the output image is...
15.4. CREATION

VerticalPitch / (HorizontalBitPitch / 8), its height is Height. The domain of the output image Image is a rectangle of the size Width * Height. The parameter HorizontalBitPitch is the horizontal distance (in bits) between two neighboring pixels. BitsPerPixel is the number of used bits per pixel.

If DoCopy is set 'true', the image data pointed to by PixelPointer is copied and memory for the new image is newly allocated by HALCON. Else the image data is not duplicated and the memory space that PixelPointer points to must be released when deleting the object Image. This is done by the procedure ClearProc provided by the caller. This procedure must have the following signature

void ClearProc(void* ptr);

and will be called using __cdecl calling convention when deleting Image. If the memory shall not be released (in the case of frame grabbers or static memory) a procedure "without trunk" or the NULL-pointer can be passed. Analogously to the parameter PixelPointer the pointer has to be passed to the procedure depending on the used operator signature and programming environment. If DoCopy is 'true' then ClearProc is irrelevant. The operator gen_image1_rect is symmetrical to get_image_pointer1_rect.

Attention

gen_image1_rect does not check whether the PixelPointer is valid or not. Thus, it must be ensured by the user that it is valid. Otherwise, the program may crash!

Parameters

- **Image** (output_object) ................................. image ~ object : byte / uint2 / int4
Created HALCON image.

- **PixelPointer** (input_control) ......................... pointer ~ integer
Pointer to the first pixel.

- **Width** (input_control) .............................. extent.x ~ integer
Width of the image.
  Default value: 512
  Suggested values: Width ∈ {128, 256, 512, 1024}
  Typical range of values: 1 ≤ Width ≤ 512 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: Width >= 1

- **Height** (input_control) .............................. extent.y ~ integer
Height of the image.
  Default value: 512
  Suggested values: Height ∈ {128, 256, 512, 1024}
  Typical range of values: 1 ≤ Height ≤ 512 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: Height >= 1

- **VerticalPitch** (input_control) ................. integer ~ integer
Distance (in bytes) between pixel m in row n and pixel m in row n+1 of the ‘input image’.
  Restriction: VerticalPitch >= Width * HorizontalBitPitch / 8

- **HorizontalBitPitch** (input_control) ........... integer ~ integer
Distance between two neighboring pixels in bits.
  Default value: 8
  List of values: HorizontalBitPitch ∈ {8, 16, 32}

- **BitsPerPixel** (input_control) ..................... integer ~ integer
Number of used bits per pixel.
  Default value: 8
  List of values: BitsPerPixel ∈ {8, 9, 10, 11, 12, 13, 14, 15, 16, 32}
  Restriction: BitsPerPixel = HorizontalBitPitch

- **DoCopy** (input_control) .......................... string ~ string
Copy image data.
  Default value: 'false'
  Suggested values: DoCopy ∈ {'true', 'false'}

- **ClearProc** (input_control) ....................... pointer ~ integer
Pointer to the procedure releasing the memory of the image when deleting the object.
  Default value: 0

HALCON 20.11.0.0
Example

```c
void NewImage(Hobject *new)
{
    unsigned char *image;
    int r,c;

    image = malloc(640*480);
    for (r=0; r<480; r++)
        for (c=0; c<640; c++)
            image[r*640+c] = c % 255;
    gen_image1_rect(new,(Hlong)image,400,480,640,8,8,'false',(long)free);
}
```

Result

The operator `gen_image1_rect` returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

- `get_image_pointer1_rect`

Alternatives

- `gen_image1`, `gen_image1Extern`, `gen_image_const`

See also

- `get_image_pointer1_rect`

Module

**Foundation**

---

### `gen_image3`

**(ImageRGB : Type, Width, Height, PixelPointerRed, PixelPointerGreen, PixelPointerBlue : )**

Create an image from three pointers to the pixels (red/green/blue).

The operator `gen_image3` creates a three-channel image of the size Width x Height. The pixels in `PixelPointerRed`, `PixelPointerGreen` and `PixelPointerBlue` are stored line-sequentially. The type of the given pixels (`PixelPointerRed` etc.) must correspond to `Type` (see `gen_image_const` for a more detailed description of the pixel types). The storage for the new image is newly created by HALCON. Thus, it can be released after the call. Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

Attention

`gen_image3` does not check whether the pixels in `PixelPointerRed`, `PixelPointerGreen`, and `PixelPointerBlue` are valid or not. Thus, it must be ensured by the user that they are valid. Otherwise, the program may crash!

Parameters

- **ImageRGB** (output_object) image ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  Created image with new image matrix.
- **Type** (input_control) string ~ string
  Pixel type.
  Default value: 'byte'
  List of values: `Type ∈ {'byte', 'direction', 'cyclic', 'int1', 'int2', 'uint2', 'int4', 'real'}`
15.4. CREATION

▷ **Width** (input_control) ............................................................................................................ extent.x \(\sim\) integer

Width of image.

Default value: 512

Suggested values: Width \(\in\) \{128, 256, 512, 1024\}

Typical range of values: \(1 \leq\) Width \(\leq 512\) (lin)

Minimum increment: 1

Recommended increment: 10

▷ **Height** (input_control) ......................................................................................................... extent.y \(\sim\) integer

Height of image.

Default value: 512

Suggested values: Height \(\in\) \{128, 256, 512, 1024\}

Typical range of values: \(1 \leq\) Height \(\leq 512\) (lin)

Minimum increment: 1

Recommended increment: 10

▷ **PixelPointerRed** (input_control) .......................................................................................... pointer \(\sim\) integer

Pointer to first red value (channel 1).

▷ **PixelPointerGreen** (input_control) ....................................................................................... pointer \(\sim\) integer

Pointer to first green value (channel 2).

▷ **PixelPointerBlue** (input_control) ......................................................................................... pointer \(\sim\) integer

Pointer to first blue value (channel 3).

--- Example ---

```c
void NewRGBImage(Hobject *new)
{
    unsigned char red[768*525];
    unsigned char green[768*525];
    unsigned char blue[768*525];
    int r,c;
    for (r=0; r<525; r++)
    for (c=0; c<768; c++)
    {
        red[r*768+c] = c % 255;
        green[r*768+c] = (767 - c) % 255;
        blue[r*768+c] = r % 255;
    }
    gen_image3(new,"byte",768,525,(Hlong)red,(long)green,(long)blue);
}
```

```c
main()
{
    Hobject rgb;
    open_window(0,0,768,525,0,"","",&WindowHandle);
    NewRGBImage(&rgb);
    disp_color(rgb,WindowHandle);
}
```

--- Result ---

If the parameter values are correct, the operator \texttt{gen\_image3} returns the value 2 (H\_MSG\_TRUE). Otherwise an exception is raised.

--- Execution Information ---

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

• Multithreading scope: global (may be called from any thread).

• Processed without parallelization.

--- Possible Predecessors ---

\texttt{gen\_image\_const, get\_image\_pointer1}

HALCON 20.11.0.0
Create a three-channel image from three pointers on the pixels with storage management.

The operator gen_image3Extern creates a three-channel image of the size Width x Height. The pixels in PointerRed, PointerGreen, and PointerBlue are stored line-sequentially. The type of the given pixels must correspond to Type (see gen_image_const for a more detailed description of the image types). Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

The memory for the new image is not newly allocated by HALCON, contrary to gen_image3, and thus is not copied either. This means that the memory space that PointerRed, PointerGreen, and PointerBlue point to must be released by deleting the object Image. This is done by the procedure ClearProc provided by the caller. This procedure must have the following signature

```c
void ClearProc(void* ptr);
```

and will be called using _cdecl calling convention when deleting Image. If the memory shall not be released (in the case of frame grabbers or static memory) a procedure “without trunk” or the NULL-Pointer can be passed. Analogous to the parameters PointerRed, PointerGreen, and PointerBlue the pointer has to be passed to the procedure depending on the used operator signature and programming environment.

gen_image3Extern does not check if enough memory for an image of Width x Height is allocated in PointerRed, PointerGreen, and PointerBlue.

Also, gen_image3Extern does not check whether the pixels in PointerRed, PointerGreen, and PointerBlue are valid or not. Thus, it must be ensured by the user that they are valid. Otherwise, the program may crash!

**Parameters**

- **Image** (output_object) ........... image \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  Created HALCON image.
- **Type** (input_control) ................................................................. string \sim string
  Pixel type.
  **Default value:** ‘byte’
  **List of values:** Type ∈ {‘int1’, ‘int2’, ‘uint2’, ‘int4’, ‘byte’, ‘real’, ‘direction’, ‘cyclic’}
- **Width** (input_control) ................................................................. extent.x \sim integer
  Width of image.
  **Default value:** 512
  **Suggested values:** Width ∈ \{128, 256, 512, 1024\}
  **Typical range of values:** 1 \leq Width \leq 512 (lin)
  **Minimum increment:** 1
  **Recommended increment:** 10
  **Restriction:** Width \geq 1
Height (input_control) .................................................. extent.y ~ integer
Height of image.
Default value: 512
Suggested values: Height ∈ {128, 256, 512, 1024}
Typical range of values: 1 ≤ Height ≤ 512 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Height ≥ 1

PointerRed (input_control) .............................................. pointer ~ integer
Pointer to the first gray value of the first channel.

PointerGreen (input_control) .......................................... pointer ~ integer
Pointer to the first gray value of the second channel.

PointerBlue (input_control) ........................................... pointer ~ integer
Pointer to the first gray value of the third channel.

ClearProc (input_control) .............................................. pointer ~ integer
Pointer to the procedure re-releasing the memory of the image when deleting the object.
Default value: 0

--- Example ---

void NewImage(Hobject *new)
{
    unsigned char *image_red;
    unsigned char *image_green;
    unsigned char *image_blue;
    int r,c;
    image_red = malloc(640*480);
    image_green = malloc(640*480);
    image_blue = malloc(640*480);
    for (r=0; r<480; r++)
        for (c=0; c<640; c++)
        {
            image_red[r*640+c] = c % 255;
            image_green[r*640+c] = (c+64) % 255;
            image_blue[r*640+c] = (c+128) % 255;
        }
    gen_image3Extern(new,"byte",640,480,(Hlong)image_red,\n(Hlong)image_green,(Hlong)image_blue,(Hlong)free);
}

--- Result ---
The operator gen_image3Extern returns the value 2 (H_MSG_TRUE) if the parameter values are correct.
Otherwise an exception is raised.

--- Execution Information ---

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

reduce_domain, paint_gray, paint_region, set_grayval

--- Module ---
Foundation
gen_image_const ( : Image : Type, Width, Height : )

Create an image with constant gray value.

The operator gen_image_const creates an image of the indicated size. The width and height of the image are determined by Width and Height. HALCON supports the following image types:

- 'byte' 1 byte per pixel, unsigned
  Value range: (0..255)

- 'int1' 1 byte per pixel, signed
  Value range: (-128..127)

- 'uint2' 2 bytes per pixel, unsigned
  Value range: (0..65535)

- 'int2' 2 bytes per pixel, signed
  Value range: (-32768..32767)

- 'int4' 4 bytes per pixel, signed
  Value range: (-2147483648..2147483647)

- 'int8' 8 bytes per pixel, signed (only available on 64 bit systems)
  Value range: (-9223372036854775808..9223372036854775807)

- 'real' 4 bytes per pixel, floating point
  Value range: (-3.4e38..3.4e38)
  Precision: 6 significant decimal digits

- 'complex' Two matrices of type 'real’

- 'vector_field_relative' Two matrices of type 'real’
  Interpretation: Vectors

- 'vector_field_absolute' Two matrices of type 'real’
  Interpretation: Absolute coordinates

- 'direction' 1 byte per pixel, unsigned
  Value range: (0..179)
  Interpretation: Angle divided by two
  Attention: The values 180..254 are automatically set to the value 255, which is interpreted as undefined angle.

- 'cyclic’ 1 byte per pixel, unsigned, cyclic arithmetics
  Value range: (0..255)

With the operator set_system('init_new_image',<true/'false'>), it can be controlled whether the created image is initialized with 0 or not.

Parameters

- Image (output_object) image
  object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

  Created image with new image matrix.

- Type (input_control) string
  Default value: 'byte'
  List of values: Type ∈ { 'byte', 'direction', 'cyclic', 'int1', 'int2', 'uint2', 'int4', 'int8', 'real', 'complex', 'vector_field_absolute', 'vector_field_relative' }

- Width (input_control) extent.x
  Default value: 512
  Suggested values: Width ∈ { 128, 256, 512, 1024 }
  Typical range of values: 1 ≤ Width ≤ 512 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: Width ≥ 1
15.4. CREATION

Height (input_control)

Height of image.

Default value: 512

Suggested values: Height ∈ \{128, 256, 512, 1024\}

Typical range of values: 1 ≤ \text{Height} ≤ 512 (lin)

Minimum increment: 1

Recommended increment: 10

Restriction: Height ≥ 1

---------- Example ----------

```c
gen_image_const(&New,"byte",width,height);
get_image_pointer1(New,(Hlong*)&pointer,type,&width,&height);
for (row=0; row<height-1; row++)
{
    for (col=0; col<width-1; col++)
    {
        pointer[row*width+col] = (row + col) % 256;
    }
}
```

---------- Result ----------

If the parameter values are correct, the operator `gen_image_const` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

---------- Execution Information ----------

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

• Multithreading scope: global (may be called from any thread).

• Processed without parallelization.

---------- Possible Successors ----------

---------- Module ----------

`Foundation`

`gen_image_gray_ramp` ( : ImageGrayRamp : Alpha, Beta, Mean, Row, Column, Width, Height : )

Create a gray value ramp.

The operator `gen_image_gray_ramp` creates a gray value ramp according to the following equation:

\[
\text{ImageGrayRamp}(r, c) = \text{Alpha}(r - \text{Row}) + \text{Beta}(c - \text{Column}) + \text{Mean}
\]

The size of the image is determined by \text{Width} and \text{Height}. The gray values are of the type 'byte'. Gray values outside the valid area are clipped.
CHAPTER 15 IMAGE

Parameters

▷ **ImageGrayRamp** (output_object) .............................................. image → object: byte
   Created image with new image matrix.

▷ **Alpha** (input_control) ................................................................. real → real
   Gradient in line direction.
   Default value: 1.0
   Suggested values: $\text{Alpha} \in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
   Minimum increment: 0.000001
   Recommended increment: -0.005

▷ **Beta** (input_control) ................................................................. real → real
   Gradient in column direction.
   Default value: 1.0
   Suggested values: $\text{Beta} \in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
   Minimum increment: 0.000001
   Recommended increment: -0.005

▷ **Mean** (input_control) ................................................................. real → real
   Mean gray value.
   Default value: 128
   Suggested values: $\text{Mean} \in \{0.0, 20.0, 40.0, 60.0, 80.0, 100.0, 120.0, 140.0, 160.0, 180.0, 200.0, 220.0, 255.0\}$
   Minimum increment: 1
   Recommended increment: 10

▷ **Row** (input_control) ................................................................. point.y → integer
   Line index of reference point.
   Default value: 256
   Suggested values: $\text{Row} \in \{128, 256, 512, 1024\}$
   Minimum increment: 1
   Recommended increment: 10

▷ **Column** (input_control) ............................................................. point.x → integer
   Column index of reference point.
   Default value: 256
   Suggested values: $\text{Column} \in \{128, 256, 512, 1024\}$
   Minimum increment: 1
   Recommended increment: 10

▷ **Width** (input_control) .............................................................. extent.x → integer
   Width of image.
   Default value: 512
   Suggested values: $\text{Width} \in \{128, 256, 512, 1024\}$
   Typical range of values: $1 \leq \text{Width} \leq 512$ (lin)
   Minimum increment: 1
   Recommended increment: 10
   Restriction: $\text{Width} \geq 1$

▷ **Height** (input_control) ............................................................. extent.y → integer
   Height of image.
   Default value: 512
   Suggested values: $\text{Height} \in \{128, 256, 512, 1024\}$
   Typical range of values: $1 \leq \text{Height} \leq 512$ (lin)
   Minimum increment: 1
   Recommended increment: 10
   Restriction: $\text{Height} \geq 1$

#### Module
- `Foundation`

```
gen_image_interleaved ( : ImageRGB : PixelPointer, ColorFormat, OriginalWidth, OriginalHeight, Alignment, Type, ImageWidth, ImageHeight, StartRow, StartColumn, BitsPerChannel, BitShift : )
```

Create a three-channel image from a pointer to the interleaved pixels.

The operator `gen_image_interleaved` creates a three-channel image from an input image, whose pixels are stored line-sequentially in `PixelPointer`. The size of the input image has to be passed in `OriginalWidth` and `OriginalHeight`, the format of the interleaved pixels in `ColorFormat`.

The output image will be sized `ImageWidth × ImageHeight`. Together with the coordinates of upper left corner `StartRow` and `StartColumn` any section of the input image can be extracted. When a 0 is passed to `ImageWidth`, `ImageHeight`, `StartRow`, and `StartColumn`, the output image will have the same dimensions as the input image.

Note that the image type `Type` (see `gen_image_const`) of the output image `ImageRGB` has to be chosen such that the whole range of possible color values of the input image can be represented. I.e. `gen_image_interleaved` does not allow to create a byte image from an input image with `ColorFormat 'rgb48'`.

When the formats 'rgb48', 'bgr48', 'rgbx64', and 'bgrx64' do not use the full range of 16 bits per channel and pixel, the number of actually used bits should be passed in `BitsPerChannel`. Furthermore, the pixel values of the input image can be shifted by `BitShift` bits to the right.

The fourth channel of four-channel input images in the formats 'rgbx', 'bgrx', 'rgbx64', and 'bgrx64' is simply discarded.

The storage for the new image is newly created by HALCON. Thus, it can be released after the call. Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

Possible values for `ColorFormat`:

- `'rgb555'`: 16 bit rgb triple (5 bit per pixel and channel), the padding bit (X) being the first bit. The bit pattern is `XRRRRGGGGBBBB`.
- `'bgr555'`: 16 bit bgr triple (5 bit per pixel and channel), the padding bit (X) being the first bit. The bit pattern is `XBBBBBGGGGRRRR`.
- `'rgb5551'`: 16 bit rgb triple (5 bit per pixel and channel), the padding bit (X) being the last bit. The bit pattern is `RRRRRGGGGBBBBXX`.
- `'bgr5551'`: 16 bit bgr triple (5 bit per pixel and channel), the padding bit (X) being the last bit. The bit pattern is `BBBBBGGGGGRRRRRX`.
- `'rgb565'`: 16 bit rgb triple (5 bit per pixel and channel, 6 bit for the green channel). The bit pattern is `RRRRRGGGGGBBBBB`.
- `'bgr565'`: 16 bit bgr triple (5 bit per pixel and channel, 6 bit for the green channel). The bit pattern is `BBBBBGGGGGRRRRRX`.
- `'rgb565'`: 16 bit rgb triple (5 bit per pixel and channel, 6 bit for the green channel). The bit pattern is `BBBBBGGGGGRRRRRX`.
- `'bgr565'`: 16 bit bgr triple (5 bit per pixel and channel, 6 bit for the green channel). The bit pattern is `BBBBBGGGGGRRRRRX`.

HALCON 20.11.0.0
'rgb': 24 bit rgb triple (8 bit per pixel and channel)
'bgr': 24 bit bgr triple (8 bit per pixel and channel)
'rgbx': 32 bit rgb quadruple (8 bit per pixel and channel)
'bgrx': 32 bit bgr quadruple (8 bit per pixel and channel)
'rgb48': 48 bit rgb triple (16 bit per pixel and channel)
'bgr48': 48 bit bgr triple (16 bit per pixel and channel)

'bgr555be': 16 bit bgr triple (5 bits per pixel and channel)
'rgb565be': 16 bit rgb triple (5 bits per pixel and channel)
'bgr565be': 16 bit bgr triple (5 bits per pixel and channel)
'rgb5551': 16 bit rgb triple (5 bits per pixel and channel)
'bgr5551': 16 bit bgr triple (5 bits per pixel and channel)
'rgb5551le': 16 bit rgb triple (5 bits per pixel and channel)
'bgr5551le': 16 bit bgr triple (5 bits per pixel and channel)
'rgb5551be': 16 bit rgb triple (5 bits per pixel and channel)
'bgr5551be': 16 bit bgr triple (5 bits per pixel and channel)

The values 'rgb555', 'bgr555', 'rgb565', 'bgr565', 'rgb5551' and 'bgr5551' can be used with the suffix 'le' (Little Endian: Lower byte is expected first) or - which is the default if the suffix is omitted - 'be' (Big Endian: Higher byte is expected first). For example, the bit pattern for ColorFormat = 'rgb555' is XRRRRRGG/GGGBBBBB, while the bit pattern for ColorFormat = 'rgb555le' is GGGBBBBB/XRRRRRGG.

**Attention**

**gen_image_interleaved** does not check whether the **PixelPointer** is valid or not. Thus, it must be ensured by the user that it is valid. Otherwise, the program may crash!

**Parameters**

- **ImageRGB** (output_object) ................................. object : byte / uint2
  Created image with new image matrix.
- **PixelPointer** (input_control) .......................... pointer : integer
  Pointer to interleaved pixels.
- **ColorFormat** (input_control) .......................... string
  Format of the input pixels.
  Default value: 'rgb'
  List of values: ColorFormat ∈ {'rgb', 'bgr', 'rgbx', 'bgrx', 'rgb48', 'bgr48', 'rgbx64', 'bgrx64', 'rgb555', 'bgr555', 'rgb565', 'bgr565', 'rgb555le', 'bgr555le', 'rgb565le', 'bgr565le', 'rgb555be', 'bgr555be', 'rgb565be', 'bgr565be', 'rgb5551', 'bgr5551', 'rgb5551le', 'bgr5551le', 'rgb5551be', 'bgr5551be'}
- **OriginalWidth** (input_control) ..................... extent.x
  Width of input image.
  Default value: 512
  Suggested values: OriginalWidth ∈ {128, 256, 512, 1024}
  Typical range of values: 1 ≤ OriginalWidth (lin)
  Minimum increment: 1
  Recommended increment: 10
- **OriginalHeight** (input_control) ...................... extent.y
  Height of input image.
  Default value: 512
  Suggested values: OriginalHeight ∈ {128, 256, 512, 1024}
  Typical range of values: 1 ≤ OriginalHeight (lin)
  Minimum increment: 1
  Recommended increment: 10
- **Alignment** (input_control) ................................ integer
  Reserved.
- **Type** (input_control) ..................................... string
  Pixel type of output image.
  Default value: 'byte'
  List of values: Type ∈ {'byte', 'uint2'}
- **ImageWidth** (input_control) ......................... rectangle.extent.x
  Width of output image.
  Default value: 0
  Suggested values: ImageWidth ∈ {128, 256, 512, 1024}
  Typical range of values: 0 ≤ ImageWidth (lin)
  Minimum increment: 1
  Recommended increment: 10
15.4. CREATION

- **ImageHeight** (input_control) .............................................. rectangle.extent.y $\sim$ integer
  Height of output image.
  Default value: 0
  Suggested values: ImageHeight $\in$ \{128, 256, 512, 1024\}
  Typical range of values: $0 \leq$ ImageHeight (lin)
  Minimum increment: 1
  Recommended increment: 10

- **StartRow** (input_control) .................................................. rectangle.origin.y $\sim$ integer
  Line number of upper left corner of desired image part.
  Default value: 0
  Suggested values: StartRow $\in$ [-1, 0]

- **StartColumn** (input_control) .............................................. rectangle.origin.x $\sim$ integer
  Column number of upper left corner of desired image part.
  Default value: 0
  Suggested values: StartColumn $\in$ [-1, 0]

- **BitsPerChannel** (input_control) ........................................ integer $\sim$ integer
  Number of used bits per pixel and channel of the output image (-1: All bits are used).
  Default value: -1
  Suggested values: BitsPerChannel $\in$ \{5, 8, 10, 12, 16, -1\}

- **BitShift** (input_control) .................................................. integer $\sim$ integer
  Number of bits that the color values of the input pixels are shifted to the right (only uint2 images).
  Default value: 0
  Suggested values: BitShift $\in$ \{0, 2, 4, 6\}

If the parameter values are correct, the operator `gen_image_interleaved` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

### Possible Successors

- `disp_color`
- `reduce_domain, paint_gray, paint_region, set_grayval, gen_image_const`

### Module

**gen_image_proto** ( Image : ImageCleared : Grayval : )

Create an image with a specified constant gray value.

`gen_image_proto` creates an output image `ImageCleared` with the constant gray value `Grayval`. If the input image is of type 'direction', gray values in result image that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. `ImageCleared` has the same dimensions and pixel type as the input image `Image`.

### Parameters

- **Image** (input_object) ...... singlechannelimage $\sim$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  Input image.

- **ImageCleared** (output_object) ...... image $\sim$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  Image with constant gray value.
**Grayval** (input_control) .......................... number  \(\sim\) real / integer
Gray value to be used for the output image.

**Default value:** 0

**Suggested values:** Grayval \(\in\) \{0, 1, 2, 5, 10, 16, 32, 64, 128, 253, 254, 255\}

---

**Result**

`gen_image_proto` returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Alternatives**

**gen_image_surface_first_order** ( : ImageSurface : Type, Alpha,
Beta, Gamma, Row, Column, Width, Height : )

Create a tilted gray surface with first order polynomial.

The operator `gen_image_surface_first_order` creates a tilted gray value surface according to the following equation:

\[
\text{ImageSurface}(r,c) = \text{Alpha}(r - \text{Row}) + \text{Beta}(c - \text{Column}) + \text{Gamma}
\]

The size of the image is determined by `Width` and `Height`. The parameters `Row` and `Column` define the reference point of the created gray surface. The gray values are of the type `Type` (see `gen_image_const` for a detailed description of the pixel types). Gray values outside the valid area are clipped.

---

**Parameters**

- **ImageSurface** (output_object) .......................... image  \(\sim\) object : byte / uint2 / real
Created image with new image matrix.

- **Type** (input_control) .......................... string  \(\sim\) string
Pixel type.

**Default value:** `byte`

**List of values:** `Type \in\` \{`byte`, `uint2`, `real`\}

- **Alpha** (input_control) .......................... number  \(\sim\) real
First order coefficient in vertical direction.

**Default value:** 1.0

**Suggested values:** Alpha \(\in\) \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}

**Minimum increment:** 0.000001

**Recommended increment:** -0.005

- **Beta** (input_control) .......................... number  \(\sim\) real
First order coefficient in horizontal direction.

**Default value:** 1.0

**Suggested values:** Beta \(\in\) \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}

**Minimum increment:** 0.000001

**Recommended increment:** -0.005

- **Gamma** (input_control) .......................... number  \(\sim\) real
Zero order coefficient.

**Default value:** 1.0

**Suggested values:** Gamma \(\in\) \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}

**Minimum increment:** 0.000001

**Recommended increment:** -0.005
15.4. CREATION

Row (input_control) .......................................................... number \(\rightarrow\) real
Row coordinate of the reference point of the surface.
Default value: 256.0
Suggested values: Row \(\in\) \{0.0, 128.0, 256.0, 512.0\}
Minimum increment: 0.000001
Recommended increment: -0.005

Column (input_control) .......................................................... number \(\rightarrow\) real
Column coordinate of the reference point of the surface.
Default value: 256.0
Suggested values: Column \(\in\) \{0.0, 128.0, 256.0, 512.0\}
Minimum increment: 0.000001
Recommended increment: -0.005

Width (input_control) ......................................................... extent.x \(\rightarrow\) integer
Width of image.
Default value: 512
Suggested values: Width \(\in\) \{128, 256, 512, 1024\}
Typical range of values: \(1 \leq\) Width \(\leq\) 512 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Width \(\geq\) 1

Height (input_control) ....................................................... extent.y \(\rightarrow\) integer
Height of image.
Default value: 512
Suggested values: Height \(\in\) \{128, 256, 512, 1024\}
Typical range of values: \(1 \leq\) Height \(\leq\) 512 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Height \(\geq\) 1

Result
If the parameter values are correct gen_image_surface_first_order returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Module

gen_image_surface_second_order ( : ImageSurface : Type, Alpha, Beta, Gamma, Delta, Epsilon, Zeta, Row, Column, Width, Height : )

Create a curved gray surface with second order polynomial.

The operator gen_image_surface_second_order creates a curved gray value surface according to the following equation:
The size of the image is determined by `Width` and `Height`. The parameters `Row` and `Column` define the reference point of the created gray surface. The gray values are of the type `Type` (see `gen_image_const` for a detailed description of the pixel types). Gray values outside the valid area are clipped.

**Parameters**

- **Imagesurface** (output_object) 
  Created image with new image matrix.

- **Type** (input_control) 
  Pixel type. 
  Default value: 'byte' 
  List of values: `Type ∈ {'byte', 'uint2', 'real'}`

- **Alpha** (input_control) 
  Second order coefficient in vertical direction. 
  Default value: 1.0 
  Suggested values: `Alpha ∈ {-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0}` 
  Minimum increment: 0.000001 
  Recommended increment: -0.005

- **Beta** (input_control) 
  Second order coefficient in horizontal direction.

- Processed without parallelization.

---

**Possible Predecessors**

fit_surface_second_order

---

**Possible Successors**

sub_image
Create an interleaved image from a multichannel image.

The operator `interleave_channels` creates an `InterleavedImage` from the input `MultichannelImage` containing three or four channels. This is useful to prepare a color image for visualization, e.g., by converting it to a .NET Bitmap.

**Pixel format**

The format of the pixels in `InterleavedImage` is specified with `PixelFormat`. Possible formats are `’rgb’`, `’rgba’`, `’argb’`, `’bgr’`, `’bgra’`, and `’abgr’`, where ‘a’ denotes the 4th (‘alpha’) channel. Be aware that, in contrast to `gen_image_interleaved`, LittleEndian byte ordering is used in `PixelFormat`.

**Alpha channel**

The alpha channel can be defined in the following ways:

<table>
<thead>
<tr>
<th>channels</th>
<th>domain</th>
<th>Value of <code>Alpha</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>not specified/full</td>
<td>Value of <code>Alpha</code> is set for the complete image.</td>
</tr>
<tr>
<td>3</td>
<td>reduced</td>
<td>Inside the domain: alpha is set to <code>Alpha</code>. Outside the domain: alpha is set to zero.</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>Alpha is set to the respective value of the fourth channel, domain and <code>Alpha</code> are ignored.</td>
</tr>
</tbody>
</table>

**Row alignment**

The number of bytes between the beginning of two rows in the output image can be set in `RowBytes`, e.g. to fulfill specific alignment criteria. Set `RowBytes` to ‘match’ if no additional padding is required. `RowBytes` must be at least the number of bytes in `PixelFormat` times the width of `MultichannelImage`.

**Parameters**

- **MultichannelImage** (input_object) : multichannel-image \( \rightarrow \) object : byte
  - Input multichannel image.
- **InterleavedImage** (output_object) : singlechannelimage \( \rightarrow \) object : byte
  - Output interleaved image.
- **PixelFormat** (input_control) : string \( \rightarrow \) string
  - Target format for InterleavedImage.
  - Default value: ‘rgba’
- **RowBytes** (input_control) : integer \( \rightarrow \) string / integer
  - Number of bytes in a row of the output image.
  - Default value: ‘match’
  - Suggested values: `RowBytes` \( \in \{’match’\}`
- **Alpha** (input_control) : integer \( \rightarrow \) integer
  - Alpha value for three channel input images.
  - Default value: 255
  - Suggested values: `Alpha` \( \in \{255, 0\}`

**Example**

```
HTuple type, width, height;
HImage patras = new HImage("patras");
```
HImage interleaved = patras.InterleaveChannels("argb", "match", 255);
IntPtr ptr = interleaved.GetImagePointer1(out type, out width, out height);
Image img = new Bitmap(width/4, height, width,
        PixelFormat.Format32bppArgb, ptr);
pictureBox.Image = img;

--- Execution Information ---

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

--- See also ---

gens_image_interleaved

--- Module ---

Foundation

region_to_bin ( Region : BinImage : ForegroundGray, BackgroundGray,
                 Width, Height : )

Convert a region into a binary byte-image.

region_to_bin converts the input region given in Region into a 'byte'-image and assigns a gray value of ForegroundGray to all pixels in the region. If the input region is larger than the generated image, it is clipped at the image borders. The background is set to BackgroundGray.

--- Parameters ---

▷ Region (input_object) ................................. region(-array) ～ object
  Regions to be converted.
▷ BinImage (output_object) ...................................... image ～ object : byte
  Result image of dimension Width × Height containing the converted regions.
▷ ForegroundGray (input_control) .............................. integer ～ integer
  Gray value in which the regions are displayed.
  Default value: 255
  Suggested values: ForegroundGray ∈ {0, 1, 50, 100, 128, 150, 200, 254, 255}
  Typical range of values: 0 ≤ ForegroundGray ≤ 255 (lin)
  Recommended increment: 1
▷ BackgroundGray (input_control) .............................. integer ～ integer
  Gray value in which the background is displayed.
  Default value: 0
  Suggested values: BackgroundGray ∈ {0, 1, 50, 100, 128, 150, 200, 254, 255}
  Typical range of values: 0 ≤ BackgroundGray ≤ 255 (lin)
  Recommended increment: 1
▷ Width (input_control) ..............................................extent.x ～ integer
  Width of the image to be generated.
  Default value: 512
  Suggested values: Width ∈ {256, 512, 1024}
  Typical range of values: 1 ≤ Width ≤ 1024 (lin)
  Minimum increment: 1
  Recommended increment: 16
  Restriction: Width >= 1
\( \text{Height} \) (input_control) \( \sim integer \)

Height of the image to be generated.

**Default value:** 512

**Suggested values:** Height \( \in \{256, 512, 1024\} \)

**Typical range of values:** \( 1 \leq \text{Height} \leq 1024 \) (lin)

**Minimum increment:** 1

**Recommended increment:** 16

**Restriction:** Height \( \geq 1 \)

\( O(2 \times \text{Height} \times \text{Width}). \)

**Result**

`region_to_bin` always returns 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)` and the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`. If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**See also**

`gen_image proto, paint_gray`

**Module**

`Foundation`

---

### region_to_label ( Region : ImageLabel : Type, Width, Height : )

**Convert regions to a label image.**

`region_to_label` converts the input regions into a label image according to their index (1..n), i.e., the first region is painted with the gray value 1, the second the gray value 2, etc. Only positive gray values are used. For 'byte'-images the index is entered modulo 256.

Regions larger than the generated image are clipped appropriately. If regions overlap the regions with the higher image are entered (i.e., they are painted in the order in which they are contained in the input regions). If so desired, the regions can be made non-overlapping by calling `expand_region`.

The background, i.e., the area not covered by any regions, is set to 0. This can be used to test in which image range no region is present.

**Parameters**

- **Region** (input_object) \( \sim object \)
  
  Regions to be converted.

- **ImageLabel** (output_object) \( \sim object : \text{byte} / \text{int2} / \text{int4} \)
  
  Result image of dimension Width \( \times \) Height containing the converted regions.

- **Type** (input_control) \( \sim string \)
  
  Pixel type of the result image.

  **Default value:** 'int2'

  **List of values:** Type \( \in \{‘\text{byte’}, ‘\text{int2’}, ‘\text{int4’}, ‘\text{int8’}\} \)
15.4. CREATION

\[ \text{Width} = \text{extent.y} \sim \text{integer} \]

Width of the image to be generated.

Default value: 512

Suggested values: Width \( \in \{64, 128, 256, 512, 1024\} \)

Typical range of values: \( 1 \leq \text{Width} \leq 1024 \) (lin)

Minimum increment: \( 1 \)

Recommended increment: 16

Restriction: Width \( \geq 1 \)

\[ \text{Height} = \text{extent.x} \sim \text{integer} \]

Height of the image to be generated.

Default value: 512

Suggested values: Height \( \in \{64, 128, 256, 512, 1024\} \)

Typical range of values: \( 1 \leq \text{Height} \leq 1024 \) (lin)

Minimum increment: \( 1 \)

Recommended increment: 16

Restriction: Height \( \geq 1 \)

\[ O(2 \cdot \text{Height} \cdot \text{Width}). \]

\[ \text{region_to_label} \] always returns 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via \text{set_system('no_object_result',<Result>)} and the behavior in case of an empty input region via \text{set_system('empty_region_result',<Result>).} If necessary, an exception is raised.

\[ \text{Execution Information} \]

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

15.5 Domain

add_channels ( Regions, Image : GrayRegions : : )

Add gray values to regions.
The operator add_channels creates an array of images GrayRegions with an element for every input region in Regions. These images correspond to the input image Image with a reduced domain, namely the intersection of the definition domain of the input image with the region. Thus, the new definition domain can be a subset of the region. Thereby the size of the image matrix is not changed and all channels of Image are adopted.

Parameters
- **Regions** (input_object) ................................. region(-array)  \(\sim\) object
  Input regions (without pixel values).
- **Image** (input_object) ...... (multichannel-)image  \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  Input image with pixel values for regions.
- **GrayRegions** (output_object) ...... image(-array)  \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  Output image(s) with regions and pixel values (one image per input region).

Number of elements: Regions == GrayRegions

Execution Information
- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

**Possible Predecessors**
- threshold, region_growing, gen_circle, draw_region

**Possible Successors**
- threshold, region_growing, get_domain

**Alternatives**
- change_domain, reduce_domain

**See also**
- full_domain, get_domain, intersection

---

**Module**

**Foundation**

---

**change_domain** ( Image, NewDomain : ImageNew : : )

*Change definition domain of an image.*

The operator `change_domain` uses the indicated region as the new definition domain. Unlike the operator `reduce_domain` it does not form the intersection of the previous definition domain, i.e., the size of the matrix is not changed. This implies in particular, that the region must not exceed the image matrix, otherwise using such inconsistent iconic objects during subsequent operations will likely lead to errors or system crashes.

---

**Attention**

Due to running time the transferred region is not checked for consistency (i.e., whether it fits with the image matrix). Incorrect regions lead to system hang-ups during subsequent operations.

---

**Parameters**

- **Image** (input_object) ...... (multichannel-)image(-array) \( \sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Input image.

- **NewDomain** (input_object) .................................................. region \( \sim \) object
  
  New definition domain.

- **ImageNew** (output_object) ...... image(-array) \( \sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Image with new definition domain.

---

**Execution Information**

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Predecessors**

**Alternatives**
- reduce_domain

**See also**
- full_domain, get_domain, intersection

---

**Module**

**Foundation**

---

**full_domain** ( Image : ImageFull : : )

*Expand the domain of an image to maximum.*
The operator `full_domain` enters a rectangle with the edge length of the image as new definition domain. This means that all pixels of the matrix are included in further operations. Thus the same definition domain is obtained as by reading or generating an image. The size of the matrix is not changed.

### Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) \(\sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  - Input image.
- **ImageFull** (output_object) ...... image(-array) \(\sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  - Image with maximum definition domain.

### Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

### Module

- `Foundation`

---

**get_domain** ( Image : Domain : )

Get the domain of an image.

The operator `get_domain` returns the definition domains of all input images as a region.

### Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) \(\sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  - Input images.
- **Domain** (output_object) ................................................................. region(-array) \(\sim \) object
  - Definition domains of input images.

### Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Module

- `Foundation`
Reduce the domain of an image to a rectangle.

The operator `rectangle1_domain` reduces the definition domain of the given image to the specified rectangle. The size of the matrix is not changed.

**Parameters**

- **Image** (input_object) ..... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Input image.

- **ImageReduced** (output_object) ..... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Image with reduced definition domain.

- **Row1** (input_control) .................................. rectangle.origin.y \(\sim\) integer
    
    Line index of upper left corner of image area.
    
    Default value: 100
    
    Suggested values: \(\text{Row1} \in \{10, 20, 50, 100, 200, 300, 500\}\)
    
    Typical range of values: \(0 \leq \text{Row1} \leq 1024\)

- **Column1** (input_control) .................................. rectangle.origin.x \(\sim\) integer
    
    Column index of upper left corner of image area.
    
    Default value: 100
    
    Suggested values: \(\text{Column1} \in \{10, 20, 50, 100, 200, 300, 500\}\)
    
    Typical range of values: \(0 \leq \text{Column1} \leq 1024\)

- **Row2** (input_control) .................................. rectangle.origin.y \(\sim\) integer
    
    Line index of lower right corner of image area.
    
    Default value: 200
    
    Suggested values: \(\text{Row2} \in \{10, 20, 50, 100, 200, 300, 500\}\)
    
    Typical range of values: \(0 \leq \text{Row2} \leq 1024\)

- **Column2** (input_control) .................................. rectangle.origin.x \(\sim\) integer
    
    Column index of lower right corner of image area.
    
    Default value: 200
    
    Suggested values: \(\text{Column2} \in \{10, 20, 50, 100, 200, 300, 500\}\)
    
    Typical range of values: \(0 \leq \text{Column2} \leq 1024\)

**Execution Information**

---

**reduce_domain** ( Image, Region : ImageReduced : : )

Reduce the domain of an image.
The operator reduce_domain reduces the definition domain of the given image to the indicated region. The new definition domain is calculated as the intersection of the old definition domain with the region. Thus, the new definition domain can be a subset of the region. The size of the matrix is not changed.

**Parameters**

- **Image** (input_object) ...... (multichannel-)image(-array) \(\rightarrow\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  Input image.
- **Region** (input_object) .................................................. region \(\rightarrow\) object
  New definition domain.
- **ImageReduced** (output_object) ...... image(-array) \(\rightarrow\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  Image with reduced definition domain.

**Execution Information**

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### 15.6 Features

#### area_center_gray ( Regions, Image : : : Area, Row, Column )

**Compute the area and center of gravity of a region in a gray value image.**

area_center_gray computes the area and center of gravity of the regions Regions that have gray values which are defined by the image Image. This operator is similar to area_center, but in contrast to that operator, the gray values of the image are taken into account while computing the area and center of gravity.

The area \(A\) of a region \(R\) in the image with the gray values \(g(r,c)\) is defined as

\[
A = \sum_{(r,c)\in R} g(r,c).
\]

This means that the area is defined by the volume of the gray value function \(g(r,c)\). The center of gravity is defined by the first two normalized moments of the gray values \(g(r,c)\), i.e., by \((m_{1,0}, m_{0,1})\), where

\[
m_{p,q} = \frac{1}{A} \sum_{(r,c)\in R} r^p c^q g(r,c).
\]

Note, that in the case where the Area is zero the row and column coordinates of the center of gravity are also set to zero.

**Attention**

Note that the operator area_center_gray only considers the given Regions and ignores any previously set domain of the input image Image. area_center_gray can be executed on OpenCL devices if the device supports the cl_khr_fp64 and cl_khr_int64_base_atomics OpenCL extensions.
15.6. FEATURES

Parameters

▷ Regions (input_object) ...................................................... region(-array) ↦ object
   Region(s) to be examined.

▷ Image (input_object) ......................................... singlechannelimage ↦ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
   Gray value image.

▷ Area (output_control) ...................................................... real(-array) ↦ real
   Gray value volume of the region.

▷ Row (output_control) ...................................................... point.y(-array) ↦ real
   Row coordinate of the gray value center of gravity.

▷ Column (output_control) ...................................................... point.x(-array) ↦ real
   Column coordinate of the gray value center of gravity.

Result

area_center_gray returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(::’no_object_result’, <Result>: ). If necessary, an exception is raised.

Execution Information

• Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Module

cooc_feature_image ( Regions, Image : : LdGray,
   Direction : Energy, Correlation, Homogeneity, Contrast )

Calculate a co-occurrence matrix and derive gray value features thereof.

The call of cooc_feature_image corresponds to the consecutive execution of the operators gen_cooc_matrix and cooc_feature_matrix. If several direction matrices of the co-occurrence matrix are to be evaluated consecutively, it is more efficient to generate the matrix via gen_cooc_matrix and then call the operator cooc_feature_matrix for the resulting matrix. The parameter Direction transfers the direction of the neighborhood in angle or ’mean’. In the case of ’mean’ the mean value is calculated in all four directions.

Attention

Note that the operator cooc_feature_image only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

▷ Regions (input_object) ...................................................... region(-array) ↦ object
   Region to be examined.

▷ Image (input_object) ......................................... singlechannelimage ↦ object : byte
   Corresponding gray values.
CHAPTER 15 IMAGE

- **LdGray** (input_control) ................................................................. integer \(\sim\) integer
  Number of gray values to be distinguished (\(2^{\text{LdGray}}\)).
  Default value: 6
  List of values: \(\text{LdGray} \in \{1, 2, 3, 4, 5, 6, 7, 8\}\)

- **Direction** (input_control) ....................................................... integer \(\sim\) integer / string
  Direction in which the matrix is to be calculated.
  Default value: 0
  List of values: \(\text{Direction} \in \{0, 45, 90, 135, \text{'mean'}\}\)

- **Energy** (output_control) .......................................................... real(-array) \(\sim\) real
  Gray value energy.

- **Correlation** (output_control) .................................................. real(-array) \(\sim\) real
  Correlation of gray values.

- **Homogeneity** (output_control) ................................................ real(-array) \(\sim\) real
  Local homogeneity of gray values.

- **Contrast** (output_control) ...................................................... real(-array) \(\sim\) real
  Gray value contrast.

The operator **cooc_feature_image** returns the value 2 (H_MSG_TRUE) if an image with defined gray values (‘byte’) is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator **set_system(:'no_object_result',<Result>:)**, the behavior in case of empty region is set via **set_system(:'empty_region_result',<Result>:)**. If necessary an exception is raised.

---

**Execution Information**

---

**cooc_feature_matrix** ( CoocMatrix : : : Energy, Correlation, Homogeneity, Contrast )

Calculate gray value features from a co-occurrence matrix.

The operator calculates from a co-occurrence matrix (CoocMatrix) the energy (Energy), correlation (Correlation), local homogeneity (Homogeneity) and contrast (Contrast).

The operator **cooc_feature_matrix** calculates the gray value features from the part of the input matrix generated by **gen_cooc_matrix** corresponding to the direction matrix indicated by the parameters **LdGray** and **Direction** according to the following formulae:

Energy:

\[
\text{Energy} = \sum_{i,j=0}^{\text{width}} c_{ij}^2
\]

(Measure for image homogeneity)

Correlation:
Correlation = $\sum_{i,j=0}^{width} \frac{(i-u_x)(j-u_y)c_{ij}}{s_x s_y}$

(Measure for gray value dependencies)

Local homogeneity:

$Homogeneity = \sum_{i,j=0}^{width} \frac{1}{1+(i-j)^2} c_{ij}$

Contrast:

$Contrast = \sum_{i,j=0}^{width} (i-j)^2 c_{ij}$

(Measure for the size of the intensity differences)

where

- $width = \text{Width of CoocMatrix}$
- $c_{ij} = \text{Entry of co-occurrence matrix}$
- $u_x = \sum_{i,j=0}^{width} i * c_{ij}$
- $u_y = \sum_{i,j=0}^{width} j * c_{ij}$
- $s_x^2 = \sum_{i,j=0}^{width} (i-u_x)^2 * c_{ij}$
- $s_y^2 = \sum_{i,j=0}^{width} (i-u_y)^2 * c_{ij}$

Attention

The region of the input image is disregarded.

Parameters

- CoocMatrix (input_object) : singlechannelimage(-array) ~ object : real
- Energy (output_control) : real ~ real
- Correlation (output_control) : real ~ real
- Homogeneity (output_control) : real ~ real
- Contrast (output_control) : real ~ real

Result

The operator cooc_feature_matrix returns the value 2 (H_MSG_TRUE) if an image with defined gray values is passed and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(‘no_object_result’,<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

gen_cooc_matrix

Alternatives

intensity, min_max_gray, entropy_gray, select_gray

Module

elliptic_axis_gray ( Regions, Image : : : Ra, Rb, Phi )

Compute the orientation and major axes of a region in a gray value image.

The operator elliptic_axis_gray calculates the length of the axes and the orientation of the ellipse having the "same orientation" and the "aspect ratio" as the input region. Several input regions can be passed in Regions as tuples. The length of the major axis Ra and the minor axis Rb as well as the orientation of the major axis with regard to the x-axis (Phi) are determined. The angle is returned in radians. The calculation is done analogously to elliptic_axis. The only difference is that in elliptic_axis_gray the gray value moments are used instead of the region moments. The gray value moments are derived from the input image Image. For the definition of the gray value moments, see area_center_gray.

Note, that in the case where the gray value area is zero the length of the axes Ra and Rb as well as the orientation Phi are also set to zero.

Attention

Note that the operator elliptic_axis_gray only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

- Regions (input_object) region(-array) object Region(s) to be examined.
- Ra (output_control) real(-array) real Major axis of the region.
- Rb (output_control) real(-array) real Minor axis of the region.
- Phi (output_control) angle.rad(-array) real Angle enclosed by the major axis and the x-axis.

Result

elliptic_axis_gray returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Foundation

HALCON/HDevelop Reference Manual, 2020-11-10
**entropy_gray** ( Regions, Image : : : Entropy, Anisotropy )

Determine the entropy and anisotropy of images.

The operator **entropy_gray** creates the histogram of relative frequencies of the gray values in the input image and calculates from these frequencies the entropy and the anisotropy coefficient for each region from **Regions** according to the following formulae:

Entropy:

\[ Entropy = - \sum_{0}^{255} rel[i] \times \log_2(rel[i]) \]

Anisotropy coefficient:

\[ Anisotropy = \frac{\sum_{0}^{k} rel[i] \times \log_2(rel[i])}{Entropy} \]

where

\[ rel[i] = \text{Histogram of relative gray value frequencies} \]
\[ i = \text{Gray value of input image (0...255)} \]
\[ k = \text{Smallest possible gray value with } \sum_{0}^{k} rel[i] \geq 0.5 \]

Attention

Note that the operator **entropy_gray** only considers the given **Regions** and ignores any previously set domain of the input image **Image**.

**Parameters**

- **Regions** (input_object) region(-array) \( \rightsquigarrow \) object
  - Regions where the features are to be determined.
- **Image** (input_object) singlechannelimage \( \rightsquigarrow \) object : byte
  - Gray value image.
- **Entropy** (output_control) real(-array) \( \rightsquigarrow \) real
  - Information content (entropy) of the gray values.
    - **Assertion:** \( 0 \leq \text{Entropy} \land \text{Entropy} \leq 8 \)
- **Anisotropy** (output_control) real(-array) \( \rightsquigarrow \) real
  - Measure of the symmetry of gray value distribution.

**Complexity**

If \( F \) is the area of the region the runtime complexity is \( O(F + 255) \).

**Result**

The operator **entropy_gray** returns the value 2 (H_MSG_TRUE) if an image with defined gray values is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator **set_system**(::’no_object_result’,<Result>:), the behavior in case of empty region is set via **set_system**(::’empty_region_result’,<Result>:). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Module**

HALCON 20.11.0.0
The operator \texttt{estimate\_noise} estimates the standard deviation of additive noise within the domain of the image that is passed in \texttt{Image}. The standard deviation is returned in \texttt{Sigma}.

The operator is useful in the following use cases:

- determination of MinContrast for matching,
- determination of the amplitude for edge filters,
- camera evaluation,
- monitoring errors in camera operation (e.g., user overdrives camera gain).

To estimate the noise, one of the following four methods can be selected in \texttt{Method}:

- \texttt{'foerstner'}: If \texttt{Method} is set to \texttt{'foerstner'}, first for each pixel a homogeneity measure is computed based on the first derivatives of the gray values of \texttt{Image}. By thresholding the homogeneity measure one obtains the homogeneous regions in the image. The threshold is computed based on a starting value for the image noise. The starting value is obtained by applying the method \texttt{'immerkaer'} (see below) in the first step. It is assumed that the gray value fluctuations within the homogeneous regions are solely caused by the image noise. Furthermore it is assumed that the image noise is Gaussian distributed. The average homogeneity measure within the homogeneous regions is then used to calculate a refined estimate for the image noise. The refined estimate leads to a new threshold for the homogeneity. The described process is iterated until the estimated image noise remains constant between two successive iterations. Finally, the standard deviation of the estimated image noise is returned in \texttt{Sigma}.

  Note that in some cases the iteration falsely converges to the value 0. This happens, for example, if the gray value histogram of the input image contains gaps that are caused either by an automatic radiometric scaling of the camera or frame grabber, respectively, or by a manual spreading of the gray values using a scaling factor $> 1$.

  Also note that the result obtained by this method is independent of the value passed in \texttt{Percent}.

- \texttt{'immerkaer'}: If \texttt{Method} is set to \texttt{'immerkaer'}, first the following filter mask is applied to the input image:

  $$M = \begin{vmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{vmatrix}.$$  

  The advantage of this method is that $M$ is almost insensitive to image structure but only depends on the noise in the image. Assuming a Gaussian distributed noise, its standard deviation is finally obtained as

  $$'\text{Sigma}' = \sqrt{\frac{\pi}{2 \cdot 6N}} \sum_{'\text{Image}'} |'\text{Image}' \ast M|,$$

  where $N$ is the number of image pixels to which $M$ is applied. Note that the result obtained by this method is independent of the value passed in \texttt{Percent}.

- \texttt{'least\_squares'}: If \texttt{Method} is set to \texttt{'least\_squares'}, the fluctuations of the gray values with respect to a locally fitted gray value plane are used to estimate the image noise. First, a homogeneity measure is computed based on the first derivatives of the gray values of \texttt{Image}. Homogeneous image regions are determined by selecting the \texttt{Percent} percent most homogeneous pixels in the domain of the input image, i.e., pixels with small magnitudes of the first derivatives. For each homogeneous pixel a gray value plane is fitted to its $3 \times 3$ neighborhood. The differences between the gray values within the $3 \times 3$ neighborhood and the locally fitted plane are used to estimate the standard deviation of the noise. Finally, the average standard deviation over all homogeneous pixels is returned in \texttt{Sigma}.

- \texttt{'mean'}: If \texttt{Method} is set to \texttt{'mean'}, the noise estimation is based on the difference between the input image and a noiseless version of the input image. First, a homogeneity measure is computed based on the first derivatives of the gray values of \texttt{Image}. Homogeneous image regions are determined by selecting the \texttt{Percent} percent most homogeneous pixels in the domain of the input image, i.e., pixels with small magnitudes of the first derivatives. A mean filter is applied to the homogeneous image regions in order to eliminate the noise. It is assumed that the difference between the input image and the thus obtained noiseless
version of the image represents the image noise. Finally, the standard deviation of the differences is returned in \( \Sigma \). It should be noted that this method requires large connected homogeneous image regions to be able to reliably estimate the noise.

Note that the methods 'foerstner' and 'immerkaer' assume a Gaussian distribution of the image noise, whereas the methods 'least_squares' and 'mean' can be applied to images with arbitrarily distributed noise. In general, the method 'foerstner' returns the most accurate results while the method 'immerkaer' shows the fastest computation.

If the image noise could not be estimated reliably, the error 3175 is raised. This may happen if the image does not contain enough homogeneous regions, if the image was artificially created, or if the noise is not of Gaussian type. In order to avoid this error, it might be useful in some cases to try one of the following modifications in dependence of the estimation method that is passed in Method:

- Increase the size of the input image domain (useful for all methods).
- Increase the value of the parameter Percent (useful for methods 'least_squares' and 'mean').
- Use the method 'immerkaer', instead of the methods 'foerstner', 'least_squares', or 'mean'. The method 'immerkaer' does not rely on the existence of homogeneous image regions, and hence is almost always applicable.

Attention Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) .................................................. singlechannelimage(-array) \( \sim \) object : byte / uint2
  Input image.
- **Method** (input_control) .................................................. string \( \sim \) string
  Method to estimate the image noise.
  Default value: 'foerstner'
  List of values: Method \( \in \{ \text{'foerstner'}, \text{'immerkaer'}, \text{'least_squares'}, \text{'mean'} \} \)
- **Percent** (input_control) .................................................. number \( \sim \) real / integer
  Percentage of used image points.
  Default value: 20
  Suggested values: Percent \( \in \{ 1, 2, 5, 7, 10, 15, 20, 30, 40, 50 \} \)
  Restriction: \( 0 \leq \text{Percent} \leq 50 \).
- **Sigma** (output_control) .................................................. real(-array) \( \sim \) real
  Standard deviation of the image noise.
  Assertion: Sigma \( \geq 0 \)

Example

```
read_image (Image, 'combine')
estimate_noise (ImageNoise, 'foerstner', 20, SigmaFoerstner)
estimate_noise (ImageNoise, 'immerkaer', 20, SigmaImmerkaer)
estimate_noise (ImageNoise, 'least_squares', 20, SigmaLeastSquares)
estimate_noise (ImageNoise, 'mean', 20, SigmaMean)
```

Result

If the parameters are valid, the operator estimate_noise returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the image noise could not be estimated reliably, the error 3175 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

fit_surface_first_order ( Regions, Image : : Algorithm, 
Iterations, ClippingFactor : Alpha, Beta, Gamma )

Calculate gray value moments and approximation by a first order surface (plane).
The operator fit_surface_first_order calculates the gray value moments and the parameters of the approximation of the gray values by a first order surface. The calculation is done by minimizing the distance between the gray values and the surface. A first order surface is described by the following formula:

\[
\text{Image}(r,c) = \text{Alpha}(r - r\_center) + \text{Beta}(c - c\_center) + \text{Gamma}
\]

r\_center and c\_center are the center coordinates of intersection of the input region with the full image domain. By the minimization process the parameters from Alpha to Gamma is calculated.

The algorithm used for the fitting can be selected via Algorithm:

- 'regression' Standard 'least squares' line fitting.
- 'huber' Weighted 'least squares' fitting, where the impact of outliers is decreased based on the approach of Huber.
- 'tukey' Weighted 'least squares' fitting, where outliers are ignored based on the approach of Tukey.

The parameter ClippingFactor (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for ClippingFactor the more outliers are detected. The detection of outliers is repeated. The parameter Iterations specifies the number of iterations. In the modus 'regression' this value is ignored.

Attention
Note that the operator fit_surface_first_order only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

- **Regions** (input_object) region(-array) *object*  
Regions to be checked.

- **Image** (input_object) singlechannelimage *byte / uint2 / direction / cyclic / real*  
Corresponding gray values.

- **Algorithm** (input_control) string *string*  
Algorithm for the fitting.  
Default value: 'regression'  
List of values: Algorithm ∈ ['regression', 'huber', 'tukey']
15.6. FEATURES

- **Iterations** (input_control) .................................................. integer ~ integer
  Maximum number of iterations (unused for 'regression').
  Default value: 5
  Restriction: Iterations >= 0

- **ClippingFactor** (input_control) .......................................... real ~ real
  Clipping factor for the elimination of outliers.
  Default value: 2.0
  List of values: ClippingFactor ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
  Restriction: ClippingFactor > 0

- **Alpha** (output_control) ...................................................... real(-array) ~ real
  Parameter Alpha of the approximating surface.

- **Beta** (output_control) ...................................................... real(-array) ~ real
  Parameter Beta of the approximating surface.

- **Gamma** (output_control) ..................................................... real(-array) ~ real
  Parameter Gamma of the approximating surface.

The operator fit_surface_first_order returns the value 2 (H_MSG_TRUE) if an image with the defined gray values ('byte') is entered and the parameters are correct. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Possible Successors

- gen_image_surface_first_order
- moments_gray_plane, fit_surface_second_order

Module

fit_surface_second_order ( Regions, Image : : Algorithm,
  Iterations, ClippingFactor : Alpha, Beta, Gamma, Delta, Epsilon,
  Zeta )

Calculate gray value moments and approximation by a second order surface.

The operator fit_surface_second_order calculates the gray value moments and the parameters of the approximation of the gray values by a second order surface. The calculation is done by minimizing the distance between the gray values and the surface. A second order surface is described by the following formula:

\[
\text{Image}(r,c) = \text{Alpha}(r - r_{\text{center}})^2 + \text{Beta}(c - c_{\text{center}})^2 + \text{Gamma}(r - r_{\text{center}}) \times (c - c_{\text{center}}) + \text{Delta}(r - r_{\text{center}}) + \text{Epsilon}(c - c_{\text{center}}) + \text{Zeta}
\]

r_{\text{center}} and c_{\text{center}} are the center coordinates of the intersection of the input region with the full image domain. By the minimization process the parameters from Alpha to Zeta is calculated.

The algorithm used for the fitting can be selected via Algorithm:
'regression' Standard 'least squares' fitting.
'huber' Weighted 'least squares' fitting, where the impact of outliers is decreased based on the approach of Huber.
'tukey' Weighted 'least squares' fitting, where outliers are ignored based on the approach of Tukey.

The parameter ClippingFactor (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for ClippingFactor the more outliers are detected. The detection of outliers is repeated. The parameter Iterations specifies the number of iterations. In the modus 'regression' this value is ignored.

Attention
Note that the operator fit_surface_second_order only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

- **Regions** (input_object) region(-array) object
  Regions to be checked.
- **Image** (input_object) singlchannelimage object: byte / uint2 / direction / cyclic / real
  Corresponding gray values.
- **Algorithm** (input_control) string
  Algorithm for the fitting.
  Default value: 'regression'
  List of values: Algorithm ∈ {'regression', 'tukey', 'huber'}
- **Iterations** (input_control) integer
  Maximum number of iterations (unused for 'regression').
  Default value: 5
  Restriction: Iterations >= 0
- **ClippingFactor** (input_control) real
  Clipping factor for the elimination of outliers.
  Default value: 2.0
  List of values: ClippingFactor ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
  Restriction: ClippingFactor > 0
- **Alpha** (output_control) real(-array)
  Parameter Alpha of the approximating surface.
- **Beta** (output_control) real(-array)
  Parameter Beta of the approximating surface.
- **Gamma** (output_control) real(-array)
  Parameter Gamma of the approximating surface.
- **Delta** (output_control) real(-array)
  Parameter Delta of the approximating surface.
- **Epsilon** (output_control) real(-array)
  Parameter Epsilon of the approximating surface.
- **Zeta** (output_control) real(-array)
  Parameter Zeta of the approximating surface.

Result

The operator fit_surface_second_order returns the value 2 (H_MSG_TRUE) if an image with the defined gray values (‘byte’) is entered and the parameters are correct. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module Foundation

fuzzy_entropy ( Regions, Image : : Apar, Cpar : Entropy )

Determine the fuzzy entropy of regions.

fuzzy_entropy calculates the fuzzy entropy of a fuzzy set. To do so, the image is regarded as a fuzzy set. The entropy then is a measure of how well the image approximates a white or black image. It is defined as follows:

\[
H(X) = \frac{1}{MN} \sum_l T_e(l) h(l)
\]

where \( M \times N \) is the size of the image, and \( h(l) \) is the histogram of the image. Furthermore,

\[
T_e(l) = -\mu(l) \ln \mu(l) - (1 - \mu(l)) \ln(1 - \mu(l))
\]

Here, \( u(x(m,n)) \) is a fuzzy membership function defining the fuzzy set (see fuzzy_perimeter). The same restrictions hold as in fuzzy_perimeter.

Attention
Note that for fuzzy_entropy, the Regions must lie completely within the previously defined domain. Otherwise an exception is raised.

Parameters

- **Regions** (input_object) region(-array) \( \sim \) object
  Regions for which the fuzzy entropy is to be calculated.
- **Image** (input_object) singlechannelimage \( \sim \) object : byte
  Input image containing the fuzzy membership values.
- **Apar** (input_control) integer
  Start of the fuzzy function.
  Default value: 0
  Suggested values: \( Apar \in \{0, 5, 10, 20, 50, 100\} \)
  Typical range of values: \( 0 \leq Apar \leq 255 \) (lin)
  Minimum increment: 1
  Recommended increment: 5
- **Cpar** (input_control) integer
  End of the fuzzy function.
  Default value: 255
  Suggested values: \( Cpar \in \{50, 100, 150, 200, 220, 255\} \)
  Typical range of values: \( 0 \leq Cpar \leq 255 \) (lin)
  Minimum increment: 1
  Recommended increment: 5
  Restriction: \( Apar \leq Cpar \)
- **Entropy** (output_control) real(-array) \( \sim \) real
  Fuzzy entropy of a region.

Example

* To find a Fuzzy Entropy from an Image
  read_image(Image,'monkey')
  fuzzy_entropy(Trans,Trans,0,255,Entro)

Result
The operator fuzzy_entropy returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

See also

References

Module Foundation

**fuzzy_perimeter** ( Regions, Image : : Apar, Cpar : Perimeter )

Calculate the fuzzy perimeter of a region.

The operator **fuzzy_perimeter** is used to determine the differences of fuzzy membership between an image point and its neighbor points. The right and lower neighbor are taken into account. The fuzzy perimeter is then defined as follows:

\[
\begin{align*}
p(X) &= \sum_{m=1}^{M-1} \sum_{n=1}^{N-1} |\mu_X(x_{m,n}) - \mu_X(x_{m,n+1})| + \sum_{m=1}^{M-1} \sum_{n=1}^{N-1} |\mu_X(x_{m,n}) - \mu_X(x_{m+1,n})| \\
\end{align*}
\]

where \(M \times N\) is the size of the image, and \(u(x(m,n))\) is the fuzzy membership function (i.e., the input image). This implementation uses Zadeh’s Standard-S function, which is defined as follows:

\[
\mu_X(x) = \begin{cases} 
0, & x \leq a \\
\frac{1}{2} \left( \frac{x-a}{c-a} \right)^2, & a < x \leq b \\
1 - 2 \left( \frac{x-a}{c-a} \right)^2, & b < x \leq c \\
1, & c \leq x 
\end{cases}
\]

The parameters \(a, b\) and \(c\) obey the following restrictions: \(b = \frac{1}{2} \Delta b\) is the inflection point of the function, \(\Delta b = b - a = c - b\) is the bandwidth, and for \(x = b \mu(x) = 0.5\) holds. In **fuzzy_perimeter**, the parameters \(\text{Apar}\) and \(\text{Cpar}\) are defined as follows: \(b = \frac{\text{Apar} + \text{Cpar}}{2}\).

Note that for **fuzzy_perimeter**, the **Regions** must lie completely within the previously defined domain. Otherwise an exception is raised.

Parameters

- **Regions** (input_object) ... region(-array) \(\sim\) object
  - Regions for which the fuzzy perimeter is to be calculated.
- **Image** (input_object) ... singlechannelimage \(\sim\) object : byte
  - Input image containing the fuzzy membership values.
- **Apar** (input_control) ... integer \(\sim\) integer
  - Start of the fuzzy function.
    - Default value: 0
    - Suggested values: \(\text{Apar} \in \{0, 5, 10, 20, 50, 100\}\)
    - Typical range of values: \(0 \leq \text{Apar} \leq 255\) (lin)
    - Minimum increment: 1
    - Recommended increment: 5
15.6. FEATURES

- **Cpar** (input_control): integer ~ integer
  End of the fuzzy function.
  **Default value:** 255
  **Suggested values:** \(Cpar \in \{50, 100, 150, 200, 220, 255\}\)
  **Typical range of values:** \(0 \leq Cpar \leq 255\) (lin)
  **Minimum increment:** 1
  **Recommended increment:** 5
  **Restriction:** \(Apar \leq Cpar\)

- **Perimeter** (output_control): real(-array) ~ real
  Fuzzy perimeter of a region.

  * To find a Fuzzy Entropy from an Image
    read_image(Image,'monkey')
    fuzzy_perimeter(Trans,Trans,0,255,Per)

  **Result**
  The operator `fuzzy_perimeter` returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

  **Execution Information**
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Automatically parallelized on tuple level.

  **Module**

- **gen_cooc_matrix** (Regions, Image : Matrix : LdGray, Direction : )

  Calculate the co-occurrence matrix of a region in an image.
  The operator `gen_cooc_matrix` determines from the input regions how often the gray values \(i\) and \(j\) are located next to each other in a certain direction \((0, 45, 90, 135\) degrees), stores this number in the co-occurrence matrix at the locations \((i,j)\) and \((j,i)\) (the matrix is symmetrical), and finally scales the matrix with the number of entries. \(LdGray\) indicates the number of gray values to be distinguished (namely \(2^{LdGray}\)).
  Example:
  **Input image with gray values (scaled with LdGray=2)**
  
<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>1</td>

  **HALCON 20.11.0.0**
Attention

Note that the operator gen_cooc_matrix only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

- **Regions** (input_object)  
  Region to be checked.
- **Image** (input_object)  
  Image providing the gray values.
- **Matrix** (output_object)  
  Co-occurrence matrix (matrices).
- **LdGray** (input_control)  
  Number of gray values to be distinguished ($2^{\text{LdGray}}$).
  Default value: 6
  List of values: $\text{LdGray} \in \{1, 2, 3, 4, 5, 6, 7, 8\}$ (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Direction** (input_control)  
  Direction of neighbor relation.
  Default value: 0
  List of values: $\text{Direction} \in \{0, 45, 90, 135\}$

Result

The operator gen_cooc_matrix returns the value 2 (H_MSG_TRUE) if an image with defined gray values is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(‘no_object_result’,<Result>), the behavior in case of empty region is set via set_system(‘empty_region_result’,<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

cocf_feature_matrix

Module

gray_features ( Regions, Image : Features : Value )

Calculates gray value features for a set of regions.

gray_features has a set of regions (Regions) as input. For each of these regions the features (Features) are calculated and returned in Value. Possible values for Features:

- ’area’  Gray value volume of region (see area_center_gray)
- ’row’  Row index of the center of gravity (see area_center_gray)
- ’column’  Column index of the center of gravity (see area_center_gray)
- ’ra’  Major axis of equivalent ellipse (see elliptic_axis_gray)
15.6. FEATURES

- 'rb'  Minor axis of equivalent ellipse (see elliptic_axis_gray)
- 'phi'  Orientation of equivalent ellipse (see elliptic_axis_gray)
- 'min'  Minimum gray value (see min_max_gray)
- 'max'  Maximum gray value (see min_max_gray)
- 'median'  Median gray value (see min_max_gray, with Percent=50)
- 'mean'  Mean gray value (see intensity)
- 'deviation'  Deviation of gray values (see intensity)
- 'plane_deviation'  Deviation from the approximating plane (see plane_deviation)
- 'anisotropy'  Anisotropy (see entropy_gray)
- 'entropy'  Entropy (see entropy_gray)
- 'fuzzy_entropy'  Fuzzy entropy of region (see fuzzy_entropy, with a fuzzy function from Apar=0 to Cpar=255)
- 'fuzzy_perimeter'  Fuzzy perimeter of region (see fuzzy_perimeter, with a fuzzy function from Apar=0 to Cpar=255)
- 'moments_row'  Mixed moments along a row (see moments_gray_plane)
- 'moments_column'  Mixed moments along a column (see moments_gray_plane)
- 'alpha'  Approximating plane, parameter Alpha (see moments_gray_plane)
- 'beta'  Approximating plane, parameter Beta (see moments_gray_plane)

Attention

Several features are processed in the order in which they are entered.

Note that the operator gray_features only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

- **Regions** (input_object) .................................................. .region-array  object
  Regions to be examined.
- **Image** (input_object) ......  singlechannelimage  object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  Gray value image.
- **Features** (input_control) .............................................. string(-array)  string
  Names of the features.
  Default value: ‘mean’
  ‘moments_column’, ‘alpha’, ‘beta’}
- **Value** (output_control) ............................................... real(-array)  real
  Values of the features.

Complexity

If F is the area of the region and N the number of features the runtime complexity is $O(F \times N)$.

Result

The operator gray_features returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
Possible Predecessors
connection, mean_image, entropy_image, sobel_amp, median_separate

Possible Successors
select_gray, shape_trans, reduce_domain, count_obj

See also
select_gray, deviation_image, entropy_gray, intensity, mean_image, min_max_gray, select_obj

Foundation

gray_histo ( Regions, Image : : : AbsoluteHisto, RelativeHisto )

Calculate the gray value distribution.
The operator gray_histo calculates for the image (Image) within Regions the absolute (AbsoluteHisto) and relative (RelativeHisto) histogram of the gray values.

Both histograms are tuples of 256 values, which — beginning at 0 — contain the frequencies of the individual gray values of the image.

AbsoluteHisto indicates the absolute frequencies of the gray values in integers, and RelativeHisto indicates the relative, i.e. the absolute frequencies divided by the area of the image as floating point numbers.

’real’-, ‘int2’-, ‘uint2’-, and ‘int4’-images are transformed into ‘byte’-images (first the largest and smallest gray value in the image are determined, and then the original gray values are mapped linearly into the area 0..255) and then processed as mentioned above.

Attention
Note that the operator gray_histo only considers the given Regions and ignores any previously set domain of the input image Image.

Real, int2, uint2, and int4 images are reduced to 256 gray values.

gray_histo can be executed on OpenCL devices for byte, int1, directional and cyclic images if the OpenCL device supports the cl_khr_local_int32_base_atomics and cl_khr_global_int32_base_atomics extensions (which are optional in OpenCL 1.0). Unlike most other HALCON operators, gray_histo can be substantially slower on an OpenCL device if the Image is not completely included in the Regions.

OpenCL support is not available in HALCON XL, as 64 bit atomic integer arithmetic would be required.

Parameters

▷ Regions (input_object) .................................................. region(-array)  arrow object
Region in which the histogram is to be calculated.

▷ Image (input_object) .... singlechannelimage  arrow object: byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Image the gray value distribution of which is to be calculated.

▷ AbsoluteHisto (output_control) ........................................................ histogram-array  arrow integer
Absolute frequencies of the gray values.

▷ RelativeHisto (output_control) ......................................................... histogram-array  arrow real
Frequencies, normalized to the area of the region.

Complexity
If F is the area of the region the runtime complexity is \( O(F + 255) \).

Result
The operator gray_histo returns the value 2 (H_MSG_TRUE) if the image has defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(::‘no_object_result’,<Result>):, the behavior in case of empty region is set via set_system(::‘empty_region_result’,<Result>):. If necessary an exception is raised.

Execution Information

• Supports OpenCL compute devices.
15.6. FEATURES

---

### gray_histo_abs (Regions, Image, Quantization, AbsoluteHisto)

Calculate the gray value distribution.

The operator `gray_histo_abs` calculates for the image (Image) within `Regions` the absolute (AbsoluteHisto) histogram of the gray values.

The parameter `Quantization` defines, how many frequencies of neighbored gray values are added for one frequency value. The resulting histogram `AbsoluteHisto` is a tuple, whose indices are mapped on the gray values of the input image `Image` and whose elements contain the frequencies of the gray values. The indices `i` of the frequency value are calculated from the gray values `g` and the quantization `q` as follows:

\[
i = \left\lfloor \frac{g + 0.5}{q} \right\rfloor \quad \text{for unsigned image types},
\]

\[
i = \left\lfloor \frac{g - (\text{MIN} - 0.5)}{q} \right\rfloor \quad \text{for signed image types},
\]

whereas `MIN` denotes the minimal gray value, e.g., -128 for an `int1` image type. Therefore, the size of the tuple results from the ratio of the full domain of gray values and the quantization, e.g. for images of `int2` in \([\frac{65536}{3.0}] = 21846\). The origin gray value of the signed image types `int1` resp. `int2` is mapped on the index 128 resp. 32768, negative resp. positive gray values have smaller resp. greater indices.

**Attention**

Note that the operator `gray_histo_abs` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

**Parameters**

- **Regions** (input_object) ................................. region(-array) \(\sim\) object
  Region in which the histogram is to be calculated.
- **Image** (input_object) ......................... singlechannelimage \(\sim\) object : byte / cyclic / direction / int1 / int2 / uint2
  Image the gray value distribution of which is to be calculated.
- **Quantization** (input_control) ................................. number \(\sim\) real / integer
  Quantization of the gray values.
  **Default value:** 1.0
  **Suggested values:** Quantization \(\in\) {1.0, 2.0, 3.0, 5.0, 10.0}
  **Restriction:** Quantization \(\geq\) 1.0
- **AbsoluteHisto** (output_control) ............................... histogram-array \(\sim\) integer
  Absolute frequencies of the gray values.

**Result**

The operator `gray_histo_abs` returns the value 2 (H_MSG_TRUE) if the image has defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(\':\'no_object_result\',<Result>;)`; the behavior in case of empty region is set via `set_system(\':\'empty_region_result\',<Result>;)` If necessary an exception is raised.

**Execution Information**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Possible Successors
histo_to_thresh, gen_region_histo

Alternatives

disp_image, histo_2dim, scale_image_max, entropy_gray

Module
Foundation

gray_histo_range (Regions, Image : : Min, Max, NumBins : Histo, BinSize )

Calculate the gray value distribution of a single channel image within a certain gray value range.

gray_histo_range calculates the gray value distribution Histo of the single channel Image within Regions and the gray value range [Min,Max]. The values for Min and Max are rounded down to the next integer if the Image is not of type ‘real’. The gray value range is divided into NumBins bins of the same size, which is returned in BinSize. If a gray value lies between two bins the gray value is assigned to the smaller bin. If the Image is of type ‘real’ BinSize = (Max-Min) / NumBins. If the Image has discrete gray values the size of a bin is computed with BinSize = (Max-Min+1) / NumBins, since the accuracy of the histogram Histo can be adjusted with NumBins. The calculation of the gray value histogram with gray_histo_range is most useful for images of type ‘real’ and images of type ‘integer’, which have a high bit depth.

Attention

Note that the operator gray_histo_range only considers the given Regions and ignores any previously set domain of the input image Image.

If the Image has discrete gray values the value of BinSize may cause the following effects: For BinSize > 1 multiple neighboring gray values are assigned to the same bin. If BinSize is an integer the gray values are distributed uneven among the bins, e.g., for BinSize = 1.5 the first and second gray value are assigned to the first bin, the third gray value is assigned to the second bin, and the fourth and fifth gray value are assigned to the third bin. This becomes noticeable in several peaks in the histogram Histo. If BinSize < 1 some classes are not assigned by any gray value, e.g., for BinSize = 0.5 the first gray value is assigned to the first bin and the second gray value is assigned to the third bin. The histogram Histo shows some gaps, which resembles the structure of a comb.

If the Image is of type ‘real’ and Min = Max, all pixels of the corresponding gray value are assigned only to the first bin.

Parameters

▷ Regions (input_object) .............................................................. region(-array) ⇒ object
Region in which the histogram is to be calculated.

▷ Image (input_object) ...... singlechannelimage ⇒ object : byte / cyclic / direction / int1 / uint2 / int2 / int4 / int8 / real
Input image.

▷ Min (input_control) .............................................................. .real ⇒ real / integer
Minimum gray value.
Default value: 0
Suggested values: Min ∈ {0}

▷ Max (input_control) .............................................................. .real ⇒ real / integer
Maximum gray value.
Default value: 255
Suggested values: Max ∈ {255}
Restriction: Max >= Min
15.6. FEATURES

• **NumBins** (input_control) .......................................................... integer ∼ integer 
  Number of bins.
  **Default value:** 256
  **Suggested values:** NumBins ∈ {16, 32, 64, 128, 256}
  **Restriction:** NumBins >= 1

• **Histo** (output_control) ........................................................... histogram(-array) ∼ integer 
  Histogram to be calculated.

• **BinSize** (output_control) ........................................................ real ∼ real 
  Bin size.

**Result**

If the parameters are valid, the operator `gray_histo_range` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

**Possible Predecessors**

`min_max_gray`

**Possible Successors**

`create_funct_1d_array`

`gray_histo, gray_histo_abs`

**See also**

`histo_2dim, scale_image_max`

**Module**

`gray_projections`

Calculate horizontal and vertical gray-value projections.

gray_projections calculates the horizontal and vertical gray-value projections, i.e., the mean values in the horizontal and vertical direction of the gray values of the input image `Image` within the input region `Region`. If `Mode = 'simple'` is selected the projection is performed in the direction of the coordinate axes of the image, i.e.:

\[
\text{HorProjection}(r) = \frac{1}{n(r + r')} \sum_{(r + r', c + c') \in \text{Region}} \text{Image}(r + r', c + c')
\]

\[
\text{VertProjection}(c) = \frac{1}{n(c + c')} \sum_{(r + r', c + c') \in \text{Region}} \text{Image}(r + r', c + c')
\]

Here, \((r', c')\) denotes the upper left corner of the smallest enclosing axis-parallel rectangle of the input region (see `smallest_rectangle1`), and \(n(x)\) denotes the number of region points in the corresponding row \(r + r'\) or column \(c + c'\). Hence, the horizontal projection returns a one-dimensional function that reflects the vertical gray value changes. Likewise, the vertical projection returns a function that reflects the horizontal gray value changes.

If `Mode = 'rectangle'` is selected the projection is performed in the direction of the major axes of the smallest enclosing rectangle of arbitrary orientation of the input region (see `smallest_rectangle2`). Here, the horizontal projection direction corresponds to the larger axis, while the vertical direction corresponds to the smaller axis. In this mode, all gray values within the smallest enclosing rectangle of arbitrary orientation of the input region are used to compute the projections.
The operator `gray_projections` only considers the given `Region` and ignores any previously set domain of the input image `Image`.

If \( n(x) = 0 \), i.e., if there are no region points in the corresponding row \( r + r' \) or column \( c + c' \), the respective value of `HorProjection` or `VertProjection` is set to \(-1\).

`gray_projections` can be executed on an OpenCL device for the 'simple' mode if the OpenCL device supports the `cl_khr_global_int32_base_atomics` OpenCL extension. For processing images of type `real`, the OpenCL device must support the `cl_khr_fp64` and `cl_khr_int64_base_atomics` extensions.

### Parameters

- **Region** (input_object) ............................... region \( \sim \) `object`
  Region to be processed.
- **Image** (input_object) ......................... singlechannelimage \( \sim \) `object` : byte / `int2` / `uint2` / `real`
  Grayvalues for projections.
- **Mode** (input_control) ........................... string \( \sim \) `string`
  Method to compute the projections.
  Default value: 'simple'
  List of values: Mode \( \in \) ['simple', 'rectangle']
- **HorProjection** (output_control) ............... real-array \( \sim \) `real`
  Horizontal projection.
- **VertProjection** (output_control) ............... real-array \( \sim \) `real`
  Vertical projection.

### Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**1D Metrology**

```plaintext
histo_2dim ( Regions, ImageCol, ImageRow : Histo2Dim : )
```

Calculate the histogram of two-channel gray value images.

The operator `histo_2dim` calculates the 2-dimensional histogram of two images within `Regions`. The gray values of channel 1 (`ImageCol`) are interpreted as row index, those of channel 2 (`ImageRow`) as column index. The gray value at one point \( P(g1,g2) \) in the output image `Histo2Dim` indicates the frequency of the gray value combination \( (g1,g2) \) with \( g1 \) indicating the line index and \( g2 \) the column index.

**Attention**

Note that the operator `histo_2dim` only considers the given `Regions` and ignores any previously set domain of the input images.

### Parameters

- **Regions** (input_object) ............................... region(-array) \( \sim \) `object`
  Region in which the histogram is to be calculated.
- **ImageCol** (input_object) ......................... (multichannel-)image \( \sim \) `object` : byte / direction / cyclic / `int1` Channel 1.
- **ImageRow** (input_object) ......................... (multichannel-)image \( \sim \) `object` : byte / direction / cyclic / `int1` Channel 2.
- **Histo2Dim** (output_object) ............................ image \( \sim \) `object` : `int4`
  Histogram to be calculated.
Example

```plaintext
read_image(Image,'monkey')
get_domain(Image, Domain)
gauss_filter(Image, ImageGauss, 7)
histo_2dim(Domain,ImageGauss, Image,Histo2Dim)
dev_display(Histo2Dim)
```

Complexity

If $F$ is the plane of the region, the runtime complexity is $O(F + 256^2)$.

Result

The operator `histo_2dim` returns the value 2 (H_MSG_TRUE) if both images have defined gray values.

The behavior in case of empty input (no input images available) is set via the operator `set_system(::{: 'no_object_result',<Result>:})`, the behavior in case of empty region is set via `set_system(::{: 'empty_region_result',<Result>:})`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`decompose3, decompose2, draw_region`

Possible Successors

`threshold, class_2dim_sup, pouring, local_max, gray_skeleton`

Alternatives

`gray_histo, gray_histo_abs`

See also

`get_grayval`

Module

`Foundation`

**intensity** (Regions, Image : : : Mean, Deviation)

Calculate the mean and deviation of gray values.

The operator `intensity` calculates the mean and the deviation of the gray values in the input image within `Regions`. If $R$ is a region, $p$ a pixel from $R$ with the gray value $g(p)$ and $F$ the plane ($F = |R|$), the features are defined by:

\[
\text{Mean} := \frac{\sum_{p \in R} g(p)}{F}
\]

\[
\text{Deviation} := \sqrt{\frac{\sum_{p \in R} (g(p) - \text{Mean})^2}{F}}
\]

Attention

Note that the operator `intensity` only considers the given `Regions` and ignores any previously set domain of the input image `Image`. The calculation of `Deviation` does not follow the usual definition if the region of the image contains only one pixel. In this case 0.0 is returned.
### Parameters

- **Regions** (input_object) ........................................... region(-array)  \( \sim \) object
  - Regions in which the features are calculated.
- **Image** (input_object) ...... singlechannelimage  \( \sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  - Gray value image.
- **Mean** (output_control) ........................................... real(-array)  \( \sim \) real
  - Mean gray value of a region.
- **Deviation** (output_control) ........................................... real(-array)  \( \sim \) real
  - Deviation of gray values within a region.

### Complexity

If \( F \) is the area of the region, the runtime complexity is \( O(F) \).

### Result

The operator `intensity` returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>):` the behavior in case of empty region is set via `set_system(::'empty_region_result',<Result>):`. If necessary an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Successors

- `threshold`

### Alternatives

- `select_gray, min_max_gray`

### See also

- `mean_image, gray_histo, gray_histo_abs`

### Module

**Foundation**

---

**min_max_gray** ( Regions, Image : : Percent : Min, Max, Range )

*Determines the minimum and maximum gray values within regions.*

The operator `min_max_gray` creates the histogram of the absolute frequencies of the gray values within `Regions` in the input image `Image` (see `gray_histo`) and calculates the number of pixels `Percent` corresponding to the area of the input image. Then it goes inwards on both sides of the histogram by this number of pixels and determines the smallest and the largest gray value:

**e.g.**

- Area = 60, percent = 5, i.e. 3 pixels
- histogram = [2,8,0,7,13,0,0,0,3,1,1]
- \( \Rightarrow \) Maximum = 255, Minimum = 0, Range = 255
- `min_max_gray` returns: Maximum = 253, Minimum = 1, Range = 252

For images of type int4, int8, and real, the above calculation is not performed via histograms, but using a rank selection algorithm. If `Percent` is set to 50, `Min = Max = Median`. If `Percent` is 0 no histogram is calculated in order to enhance the runtime.

---

**Attention**

Note that the operator `min_max_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

---

HALCON/HDevelop Reference Manual, 2020-11-10
15.6. FEATURES

Parameters

- **Regions** (input_object) .......................... region(-array) \( \sim \) object
  Regions, the features of which are to be calculated.

- **Image** (input_object) ............. singlechannelimage \( \sim \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4
  / int8 / real
  Gray value image.

- **Percent** (input_control) .................. number \( \sim \) real / integer
  Percentage below (above) the absolute maximum (minimum).
  **Default value:** 0
  **Suggested values:** Percent \( \in \) \{0, 1, 2, 5, 7, 10, 15, 20, 30, 40, 50\}
  **Restriction:** 0 \( \leq \) Percent \&\& Percent \( \leq \) 50

- **Min** (output_control) ................. real(-array) \( \sim \) real
  “Minimum” gray value.
  **Assertion:** Min \( \geq \) Min

- **Max** (output_control) ................. real(-array) \( \sim \) real
  “Maximum” gray value.
  **Assertion:** Max \( \geq \) Min

- **Range** (output_control) ............... real(-array) \( \sim \) real
  Difference between Max and Min.
  **Assertion:** Range \( \geq \) 0

Example

* Threshold segmentation with training region:
  read_image(Image,'fabrik')
  draw_region(Region,WindowHandle)
  min_max_gray(Region,Image,5,Min,Max,Range)
  threshold(Image,SegmentedRegion,Min,Max)
  dev_display(SegmentedRegion)

Result

The operator `min_max_gray` returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system::<\'no_object_result\',<Result>>`. The behavior in case of an empty region is set via the operator `set_system::<\'empty_region_result\',<Result>>`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

draw_region, gen_circle, gen_ellipse, gen_rectangle1, threshold, regiongrowing

Possible Successors

threshold

Alternatives

select_gray, intensity

See also

gray_histo, scale_image, scale_image_max, learn_ndim_norm

Module

**moments_gray Plane** ( Regions, Image : : : MRow, MCol, Alpha, Beta, Mean )

Calculate gray value moments and approximation by a plane.
The operator `moments_gray_plane` calculates the gray value moments and the parameters of the approximation of the gray values by a plane. The calculation is carried out according to the following formula:

\[
\begin{align*}
M_{\text{Row}} &= \frac{1}{F^2} \sum_{(r,c) \in \text{Regions}} (r - \tau)(\text{Image}(r,c) - \text{Mean}) \\
M_{\text{Col}} &= \frac{1}{F^2} \sum_{(r,c) \in \text{Regions}} (c - \tau)(\text{Image}(r,c) - \text{Mean})
\end{align*}
\]

where \( F \) is the plane, \( \tau \) the center, and \( m_{11}, m_{20}, \) and \( m_{02} \) the scaled moments of \( \text{Regions} \).

The parameters `Alpha`, `Beta` and `Mean` describe a plane above the region:

\[
\text{Image}'(r,c) = \text{Alpha}(r - \tau) + \text{Beta}(c - \tau) + \text{Mean}
\]

Thus `Alpha` indicates the gradient in the direction of the line axis (“down”), `Beta` the gradient in the direction of the column axis (to the “right”).

**Attention**

Note that the operator `moments_gray_plane` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

**Parameters**

- `Regions` (input_object) ......... region(-array) \( \leadsto \) object
  Regions to be checked.
- `Image` (input_object) ......... singlechannelimage \( \leadsto \) object : byte / direction / cyclic / uint2 / real
  Corresponding gray values.
- `MRow` (output_control) .......... real(-array) \( \leadsto \) real
  Mixed moments along a line.
- `MCol` (output_control) .......... real(-array) \( \leadsto \) real
  Mixed moments along a column.
- `Alpha` (output_control) ......... real(-array) \( \leadsto \) real
  Parameter `Alpha` of the approximating plane.
- `Beta` (output_control) .......... real(-array) \( \leadsto \) real
  Parameter `Beta` of the approximating plane.
- `Mean` (output_control) .......... real(-array) \( \leadsto \) real
  Mean gray value.

**Result**

The operator `moments_gray_plane` returns the value 2 (H_MSG_TRUE) if an image with the defined gray values (“byte”) is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::’no_object_result’,<Result>:)`, the behavior in case of empty region is set via `set_system(::’empty_region_result’,<Result>:)`. If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Predecessors**

`draw_region, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, threshold, regiongrowing`

**See also**

`intensity, moments_region_2nd`

**References**

**Module**

HALCON/HDevelop Reference Manual, 2020-11-10
**plane_deviation** (Regions, Image : : : Deviation )

**Calculate the deviation of the gray values from the approximating image plane.**

The operator `plane_deviation` calculates the deviation of the gray values in `Image` from the approximation of the gray values through a plane. Contrary to the standard deviation in case of intensity slanted gray value planes also receive the value zero. The gray value plane is calculated according to `gen_image_gray_ramp`. If \( F \) is the area of the region, \( \alpha, \beta, \) and \( \mu \) the parameters of the image plane, and \( (r',c') \) the center of the region, Deviation is defined by:

\[
\text{Deviation} = \sqrt{\frac{\sum_{(r,c) \in \text{Regions}} ((\alpha(r - r') + \beta(c - c') + \mu) - \text{Image}(r,c))^2}{F}}.
\]

**Attention**

Note that the operator `plane_deviation` only considers the given `Regions` and ignores any previously set domain of the input image `Image`. It should be noted that the calculation of `Deviation` does not follow the usual definition. It is defined to return the value 0.0 for an image with only one pixel.

**Parameters**

- **Regions** (input_object) : region(-array) \( \leadsto \) object
  Regions, of which the plane deviation is to be calculated.
- **Image** (input_object) : singlechannelimage \( \leadsto \) object : byte / cyclic
  Gray value image.
- **Deviation** (output_control) : real(-array) \( \leadsto \) real
  Deviation of the gray values within a region.

**Complexity**

If \( F \) is the area of the region the runtime complexity amounts to \( O(F) \).

**Result**

The operator `plane_deviation` returns the value 2 (H_MSG_TRUE) if `Image` is of the type 'byte'. The behavior in case of empty input (no input images available) is set via the operator `set_system(:: 'no_object_result',<Result>:)`, the behavior in case of empty region is set via `set_system(:: 'empty_region_result',<Result>:)`. If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Alternatives**

- `intensity`, `gen_image_gray_ramp`, `sub_image`

**See also**

- `moments_gray_plane`

**Module**

- `select_gray` (Regions, Image : SelectedRegions : Features, Operation, Min, Max : )

**Select regions based on gray value features.**

The operator `select_gray` has a number of regions (`Regions`) as input. For each of these regions the (`Features`) are calculated. The region is transferred (duplicated) into the output `SelectedRegions`, if each (`Operation` = 'and') or at least one (`Operation` = 'or') of the calculated features is within the limits. The limits are defined by the parameters `Min` and `Max`. Thereby, `Min` and `Max` can also be set to 'min' or 'max', respectively, corresponding to setting the smallest or largest value possible for this feature. The parameter `Image`
contains an image which returns the gray values for calculating the features. Condition:

\[ \text{Min}_i \leq \text{Features}_i(\text{Regions, Image}) \leq \text{Max}_i \]

- **area** Gray value volume of region (see area_center_gray)
- **row** Row index of the center of gravity (see area_center_gray)
- **column** Column index of the center of gravity (see area_center_gray)
- **ra** Major axis of equivalent ellipse (see elliptic_axis_gray)
- **rb** Minor axis of equivalent ellipse (see elliptic_axis_gray)
- **phi** Orientation of equivalent ellipse (see elliptic_axis_gray)
- **min** Minimum gray value (see min_max_gray)
- **max** Maximum gray value (see min_max_gray)
- **median** Median gray value (see min_max_gray, with Percent=50)
- **mean** Mean gray value (see intensity)
- **deviation** Deviation of gray values (see intensity)
- **plane_deviation** Deviation from the approximating plane (see plane_deviation)
- **anisotropy** Anisotropy (see entropy_gray)
- **entropy** Entropy (see entropy_gray)
- **fuzzy_entropy** Fuzzy entropy of region (see fuzzy_entropy, with a fuzzy function from Apar=0 to Cpar=255)
- **fuzzy_perimeter** Fuzzy perimeter of region (see fuzzy_perimeter, with a fuzzy function from Apar=0 to Cpar=255)
- **moments_row** Mixed moments along a row (see moments_gray_plane)
- **moments_column** Mixed moments along a column (see moments_gray_plane)
- **alpha** Approximating plane, parameter Alpha (see moments_gray_plane)
- **beta** Approximating plane, parameter Beta (see moments_gray_plane)

**Attention**

Note that the operator select_gray only considers the given Regions and ignores any previously set domain of the input image Image. If only one feature is used the value of Operation is meaningless. Several features are processed in the order in which they are entered. The maximum number of features is limited to 100.

**Parameters**

- **Regions** (input_object) ...................................................... region-array \( \rightarrow \) object
  Regions to be examined.
- **Image** (input_object) ...... singlechannelimage \( \rightarrow \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
  Gray value image.
- **SelectedRegions** (output_object) ...................................... region-array \( \rightarrow \) object
  Regions having features within the limits.
- **Features** (input_control) ............................................... string(-array) \( \rightarrow \) string
  Names of the features.
  Default value: ‘mean’
  List of values: Features \( \in \{ \text{'area', 'row', 'column', 'ra', 'rb', 'phi', 'min', 'max', 'median', 'mean', 'deviation', 'plane_deviation', 'anisotropy', 'entropy', 'fuzzy_entropy', 'fuzzy_perimeter', 'moments_row', 'moments_column', 'alpha', 'beta' \} \)
- **Operation** (input_control) .............................................. string \( \rightarrow \) string
  Logical connection of features.
  Default value: ‘and’
  List of values: Operation \( \in \{ \text{'and', 'or'} \} \)
15.6. FEATURES

Min (input_control) ............................................................number(-array) \sim real / integer / string
Lower limit(s) of features or ‘min’.
Default value: 128.0
Suggested values: Min \in \{0.5, 1.0, 10.0, 20.0, 50.0, 128.0, 255.0, 1000.0, 'min'\}

Max (input_control) ............................................................number(-array) \sim real / integer / string
Upper limit(s) of features or ‘max’.
Default value: 255.0
Suggested values: Max \in \{0.5, 1.0, 10.0, 20.0, 50.0, 128.0, 255.0, 1000.0, 'max'\}

Complexity
If \( F \) is the area of the region and \( N \) the number of features the runtime complexity is \( \mathcal{O}(F \times N) \).

Result
The operator select_gray returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(::’no_object_result’,<Result>:), the behavior in case of empty region is set via set_system(::’empty_region_result’,<Result>:). If necessary an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors
connection, mean_image, entropy_image, sobel_amp, median_separate

Possible Successors
select_shape, shape_trans, reduce_domain, count_obj

See also
deviation_image, entropy_gray, intensity, mean_image, min_max_gray, select_obj

Module
Foundation

shape_histo_all ( Region, Image : : Feature : AbsoluteHisto,
RelativeHisto )

Determine a histogram of features along all threshold values.
The operator shape_histo_all carries out 255 threshold operations within Region with the gray values of Image. The entry \( i \) in the histogram corresponds to the number of connected components/holes of this image segmented with the threshold \( i \) (Feature = ’connected_components’, ’holes’) or the mean value of the feature values of the regions segmented in this way (Feature = ’convexity’, ’compactness’, ’anisometry’), respectively.

Attention
The operator shape_histo_all expects a region and exactly one gray value image as input. Because of the power of this operator the runtime of shape_histo_all is relatively large!

Note that the operator shape_histo_all only considers the given Region and ignores any previously set domain of the input image Image.

Parameters

Region (input_object) ............................................................region \sim object
Region in which the features are to be examined.

Image (input_object) ............................................................singlechannelimage \sim object : byte
Gray value image.

Feature (input_control) ............................................................string \sim string
Feature to be examined.
Default value: ’connected_components’
List of values: Feature \in \{’connected_components’, ’convexity’, ’compactness’, ’anisometry’, ’holes’\}
**AbsoluteHisto** (output_control) ...................... histogram-array \(\sim real / integer\)
Absolute distribution of the feature.

**RelativeHisto** (output_control) ...................... histogram-array \(\sim real\)
Relative distribution of the feature.

---

**Example**

* Simulation of shape_histo_all with feature 'connected_components':
  * my_shape_histo_all(Region,Image,AbsHisto,RelHisto):

```
reduce_domain(Region,Image,RegionGray)
for i := 0 to 255 by 1
  threshold(RegionGray,Seg,i,255)
  connect_and_holes (Seg, NumConnected, _)
  AbsHisto[i] := NumConnected
endfor
Sum := 0
for i := 0 to 255 by 1
  Sum := Sum+AbsHisto[i]
endfor
for i := 0 to 255 by 1
  RelHisto[i] := AbsHisto[i]/Sum
endfor
```

---

**Complexity**

If \(F\) is the area of the input region and \(N\) the mean number of connected components the runtime complexity is \(O(255(F + \sqrt{F} \sqrt{N}))\).

---

**Result**

The operator shape_histo_all returns the value 2 (H_MSG_TRUE) if an image with the defined gray values is entered. The behavior in case of empty input (no input images) is set via the operator set_system(:: 'no_object_result',<Result>:), the behavior in case of empty region is set via set_system(:: 'empty_region_result',<Result>):). If necessary an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Module**

Foundation

---

**shape_histo_point** ( Region, Image : : Feature, Row,
  Column : AbsoluteHisto, RelativeHisto )

Determine a histogram of features along all threshold values.

Like shape_histo_all the operator shape_histo_point carries out 255 threshold value operations within Region with the gray values of Image. Contrary to shape_histo_all only the segmented region containing the pixel (Row, Column) is taken into account here. The entry \(i\) in the histogram then corresponds to
the number of holes of this region segmented with the threshold \(i\) (Feature = 'holes') or the feature value of the region (Feature = 'convexity', 'compactness', 'anisometry'), respectively.

**Attention** Note that the operator `shape_histo_point` only considers the given `Region` and ignores any previously set domain of the input image `Image`.

**Parameters**

- **Region** (input_object) Region in which the features are to be examined. Default value: 'convexity'
  
- **Image** (input_object) Gray value image. Default value: 256
  
- **Feature** (input_control) Feature to be examined. Default value: 'convexity'
  
- **Row** (input_control) Row of the pixel which the region must contain. Default value: 256
  
- **Column** (input_control) Column of the pixel which the region must contain. Default value: 256
  
- **AbsoluteHisto** (output_control) Absolute distribution of the feature. Default value: 256
  
- **RelativeHisto** (output_control) Relative distribution of the feature. Default value: 256

**Result**

The operator `shape_histo_point` returns the value 2 (H_MSG_TRUE) if an image with defined gray values is entered. The behavior in case of empty input (no input images available) is set via the operator `set_system(::{'no_object_result',<Result>:})`, the behavior in case of empty region is set via `set_system(::{'empty_region_result',<Result>:})`. If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

**Possible Predecessors**

15.7 Format

```
change_format ( Image : ImagePart : Width, Height : )
```

`change_format` changes image size.
The operator change_format increases or decreases the size of the input images to the indicated height or width, respectively. If the image is reduced, parts are cut off at the “right” or “lower” edge of the image, respectively. If the image is enlarged, the additional areas are set to 0. The definition domain of the new image is equal to the domain of the input image, clipped to the size of the new image. No zooming is carried out.

Parameters

Image (input_object) (multichannel-)image(-array)  \(\leadsto\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Input image.

ImagePart (output_object) (multichannel-)image(-array)  \(\leadsto\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Image with new format.

Width (input_control) extent.x  \(\leadsto\) integer

Width of new image.

Default value: 512
Suggested values: Width \(\in\) \{32, 64, 128, 256, 512, 768, 1024\}

Height (input_control) extent.y  \(\leadsto\) integer

Height of new image.

Default value: 512
Suggested values: Height \(\in\) \{32, 64, 128, 256, 512, 525, 1024\}

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Successors
disp_image

Alternatives
crop_part

See also
crop_domain

Module
crop_domain ( Image : ImagePart : : )

Cut out of defined gray values.

The operator crop_domain cuts a rectangular area from the input images. This rectangle is the smallest surrounding rectangle of the domain of the input image. The new image matrix has the size of the rectangle.

Parameters

Image (input_object) (multichannel-)image(-array)  \(\leadsto\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

Input image.

ImagePart (output_object) (multichannel-)image(-array)  \(\leadsto\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

Image area.

Execution Information

• Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Successors

disp_image

Module
Foundation

crop_domain_rel ( Image : ImagePart : Top, Left, Bottom, Right : )

Cut out an image area relative to the domain.

crop_domain_rel cuts a rectangular area from the input images. The area is determined by the surrounding rectangle of the domain of the input image. The rectangle can be influenced by the control parameters to modify at the top (Top), at the left (Left), at the bottom (Bottom), and at the right (Right). Positive values result in a smaller, negative values in a larger size. If all parameters are set to zero, the region remains unchanged.

Parameters

▷ Image (input_object) . . . . . . (multichannel-)image(-array) ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real

Input image.

▷ ImagePart (output_object) . . . . . . (multichannel-)image(-array) ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real

Image area.

▷ Top (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer ~ integer

Number of rows clipped at the top.

Default value: -1

Suggested values: Top ∈ {-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20}

▷ Left (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer ~ integer

Number of columns clipped at the left.

Default value: -1

Suggested values: Left ∈ {-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20}

▷ Bottom (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer ~ integer

Number of rows clipped at the bottom.

Default value: -1

Suggested values: Bottom ∈ {-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20}

▷ Right (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer ~ integer

Number of columns clipped at the right.

Default value: -1

Suggested values: Right ∈ {-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20}

Result
crop_domain_rel returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.

### Module
Foundation

### **crop_part**  
(Image : ImagePart : Row, Column, Width, Height : )

Cut out one or more rectangular image areas.

The operator `crop_part` cuts one or more rectangular area from each of the input images. The areas are indicated by rectangles, which are defined by the coordinates of their upper left corner and by their size. The upper left corners of the rectangles must be within the image. At the right side and at the bottom, the rectangles may exceed the image, but the domain of the output images is set so that only the part that can be derived from the input image is contained. If the rectangular areas fall completely within the image, then each of the resulting images has the size of its corresponding rectangle.

#### Parameters

- **Image**  (input_object)  
  (multichannel-)image(-array)  
  object : byte / direction / cyclic / int1 / int2 / uint2 / uint4 / int8 / real
  Input image.

- **ImagePart**  (output_object)  
  (multichannel-)image(-array)  
  object : byte / direction / cyclic / int1 / int2 / uint2 / uint4 / int8 / real
  Image area.

- **Row**  (input_control)  
  rectangle.origin.y(-array)  
  integer
  Line index of upper left corner of image area.
  **Default value:** 100
  **Suggested values:** Row \( \in \{10, 20, 50, 100, 200, 300, 500\}\)
  **Typical range of values:** \(0 \leq \text{Row} \leq 1024\)

- **Column**  (input_control)  
  rectangle.origin.x(-array)  
  integer
  Column index of upper left corner of image area.
  **Default value:** 100
  **Suggested values:** Column \( \in \{10, 20, 50, 100, 200, 300, 500\}\)
  **Typical range of values:** \(0 \leq \text{Column} \leq 1024\)

- **Width**  (input_control)  
  rectangle.extent.x(-array)  
  integer
  Width of new image.
  **Default value:** 128
  **Suggested values:** Width \( \in \{32, 64, 128, 256, 512, 768\}\)
  **Typical range of values:** \(0 \leq \text{Width} \leq 1024\)

- **Height**  (input_control)  
  rectangle.extent.y(-array)  
  integer
  Height of new image.
  **Default value:** 128
  **Suggested values:** Height \( \in \{32, 64, 128, 256, 512, 525\}\)
  **Typical range of values:** \(0 \leq \text{Height} \leq 1024\)

#### Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module
Foundation

crop_rectangle1 ( Image : ImagePart : Row1, Column1, Row2, Column2 : )

Cut out one or more rectangular image areas.

The operator `crop_rectangle1` cuts one or more rectangular areas from each of the input images. The areas are indicated by rectangles, which are defined by the coordinates of their upper left and their lower right corners. The upper left corners must be within the image. At the right side and at the bottom, the rectangles may exceed the image, but the domain of the output images is set so that only the part that can be derived from the input image is contained. If the rectangular areas fall within the image, then each of the resulting images has the size of its corresponding rectangle.

Parameters

- **Image** (input_object) ....... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  
  Input image.

- **ImagePart** (output_object) ....... (multichannel-)image(-array) \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  
  Image area.

- **Row1** (input_control) .......................................................... rectangle.origin.y(-array) \(\sim\) integer
  
  Line index of upper left corner of image area.
  
  **Default value:** 100
  
  **Suggested values:** \(\text{Row1} \in \{10, 20, 50, 100, 200, 300, 500\}\)
  
  **Typical range of values:** \(0 \leq \text{Row1} \leq 1024\)

- **Column1** (input_control) ...................................................... rectangle.origin.x(-array) \(\sim\) integer
  
  Column index of upper left corner of image area.
  
  **Default value:** 100
  
  **Suggested values:** \(\text{Column1} \in \{10, 20, 50, 100, 200, 300, 500\}\)
  
  **Typical range of values:** \(0 \leq \text{Column1} \leq 1024\)

- **Row2** (input_control) .......................................................... rectangle.corner.y(-array) \(\sim\) integer
  
  Line index of lower right corner of image area.
  
  **Default value:** 200
  
  **Suggested values:** \(\text{Row2} \in \{10, 20, 50, 100, 200, 300, 500\}\)
  
  **Typical range of values:** \(0 \leq \text{Row2} \leq 1024\)

- **Column2** (input_control) ...................................................... rectangle.corner.x(-array) \(\sim\) integer
  
  Column index of lower right corner of image area.
  
  **Default value:** 200
  
  **Suggested values:** \(\text{Column2} \in \{10, 20, 50, 100, 200, 300, 500\}\)
  
  **Typical range of values:** \(0 \leq \text{Column2} \leq 1024\)

**Module**

**crop_rectangle2** (Image : ImagePart : Row, Column, Phi, Length1, Length2, AlignToAxis, Interpolation : )

Cut out one or more arbitrarily oriented rectangular image areas.

`crop_rectangle2` cuts one or more rectangular areas from each of the input images. The areas are indicated by rectangles, which are defined by the center (Row, Column), the orientation Phi and the half edge lengths Length1 and Length2. Phi is given in arc measure in mathematically positive direction and indicates the angle between the horizontal axis and the first edge (with length Length1). The rectangle parameters use pixel centered, subpixel accurate coordinates, see Transformations / 2D Transformations.

The parameter AlignToAxis determines the alignment of the output image. Possible values:

- 'true': The cropped image part is rotated such that it is aligned with the coordinate axes. For this, a suitable interpolation must be performed. A detailed description of the interpolation modes can be found in the description of `affine_trans_image`. The rectangle may protrude the input image. Gray values of pixels lying outside the input image are set to 0.
- 'false': The smallest surrounding rectangle of the input rectangle is cut out and the domain is set accordingly. The rectangle may exceed the input image boundaries. However, the size of the resulting cropped image part is determined by the portion of the rectangle which lies within the input image boundaries. For this method no interpolation is required. Therefore, the parameter Interpolation has no effect.

**Parameters**

- **Image** (input_object) ....................... (multichannel-)image-array ~ object : byte / int2 / uint2 / real
  Input image(s).
- **ImagePart** (output_object) ................. (multichannel-)image-array ~ object : byte / int2 / uint2 / real
  Cropped image part(s).
- **Row** (input_control) .......................... rectangle2.center.y(-array) ~ real / integer
  Row index of the image crop center.
  Default value: 300.0
  Suggested values: Row ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0} (lin)
  Recommended increment: 10.0
- **Column** (input_control) ....................... rectangle2.center.x(-array) ~ real / integer
  Column index of the image crop center.
  Default value: 200.0
  Suggested values: Column ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0} (lin)
  Recommended increment: 10.0
- **Phi** (input_control) ............................ rectangle2.angle.rad(-array) ~ real / integer
  Orientation of the rectangle (arc measure).
  Default value: 0.0
  Suggested values: Phi ∈ [-1.178097, -0.785398, -0.392699, 0.0, 0.392699, 0.785398, 1.178097]
  Typical range of values: -1.178097 ≤ Phi ≤ 1.178097 (lin)
15.7. FORMAT

DIV.Length1 (input_control) ...........................................rectangle2.hwidth(-array)  \sim real / integer
First half edge length of the rectangle.
Default value: 100.0
Suggested values: Length1 \in \{3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0, 300.0, 500.0\}
Recommended increment: 10.0

DIV.Length2 (input_control) ...........................................rectangle2.hheight(-array)  \sim real / integer
Second half edge length of the rectangle.
Default value: 20.0
Suggested values: Length2 \in \{1.0, 2.0, 3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0\}
Recommended increment: 10.0

DIV.AlignToAxis (input_control) ...........................................string  \sim string
Determines whether the cropped image part is aligned with the coordinate axes.
Default value: 'true'
List of values: AlignToAxis \in \{'true', 'false'\}

DIV.Interpolation (input_control) ...........................................string  \sim string
Interpolation method.
Default value: 'constant'
List of values: Interpolation \in \{'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'\}

**tile_channels** ( Image : TiledImage : NumColumns, TileOrder : )

Tile multiple images into a large image.

*tile_channels* tiles an image consisting of multiple channels into a large single-channel image. The input image *Image* contains *Num* images of the same size, which are stored in the individual channels. The output image *TiledImage* contains a single channel image, where the *Num* input channels have been tiled into *NumColumns* columns. In particular, this means that *tile_channels* cannot tile color images. For this purpose, *tile_images* can be used. The parameter *TileOrder* determines the order in which the images are copied into the output in the cases in which this is not already determined by *NumColumns* (i.e., if *NumColumns* \neq 1 and *NumColumns* \neq *Num*). If *TileOrder* = 'horizontal' the images are copied in the horizontal direction, i.e., the second channel of *Image* will be to the right of the first channel. If *TileOrder* = 'vertical' the images are copied in the vertical direction, i.e., the second channel of *Image* will be below the first channel. The domain of *TiledImage* is obtained by copying the domain of *Image* to the corresponding locations in the output image. If *Num* is not a multiple of *NumColumns* the output image will have undefined gray values in the lower right corner of the image. The output domain will reflect this.
Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) \(\sim object : \) byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Input image.

- **TiledImage** (output_object) ...... singlechannelimage(-array) \(\sim object : \) byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Tiled output image.

- **NumColumns** (input_control) ................................................................. integer \(\sim integer\)
  Number of columns to use for the output image.
  Default value: 1
  Suggested values: NumColumns \(\in\{1, 2, 3, 4, 5, 6, 7\}\)
  Restriction: NumColumns \(\geq 1\)

- **TileOrder** (input_control) ................................................................. string \(\sim string\)
  Order of the input images in the output image.
  Default value: 'vertical'
  List of values: TileOrder \(\in\{'horizontal', 'vertical'\}\)

Example

* Grab 5 single-channel images and stack them vertically.
  gen_rectangle1 (Image, 0, 0, Height-1, Width-1)
  for I := 1 to 5 by 1
    grab_image_async (ImageGrabbed, AcqHandle, -1)
    append_channel (Image, ImageGrabbed, Image)
  endfor
  tile_channels (Image, TiledImage, 1, 'vertical')

Result

tile_channels returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(:,:,no_object_result,’<Result>‘). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

append_channel

```
tile_images ( Images : TiledImage : NumColumns, TileOrder : )
```

Tile multiple image objects into a large image.

tile_images tiles multiple input image objects, which must contain the same number of channels, into a large image. The input image object Images contains Num images, which may be of different size. The output image TiledImage contains as many channels as the input images. In the output image the Num input images have been tiled into NumColumns columns. Each tile has the same size, which is determined by the maximum width and height of all input images. If an input image is smaller than the tile size it is copied to the center of the respective
The parameter **TileOrder** determines the order in which the images are copied into the output in the cases in which this is not already determined by **NumColumns** (i.e., if **NumColumns** ≠ 1 and **NumColumns** ≠ **Num**). If **TileOrder** = 'horizontal' the images are copied in the horizontal direction, i.e., the second image of **Images** will be to the right of the first image. If **TileOrder** = 'vertical' the images are copied in the vertical direction, i.e., the second image of **Images** will be below the first image. The domain of **TiledImage** is obtained by copying the domains of **Images** to the corresponding locations in the output image. If **Num** is not a multiple of **NumColumns** the output image will have undefined gray values in the lower right corner of the image. The output domain will reflect this.

---

### Parameters

- **Images** *(input_object) .... (multichannel-)image-array → object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real*
  
  Input images.

- **TiledImage** *(output_object) .... (multichannel-)image → object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real*
  
  Tiled output image.

- **NumColumns** *(input_control) ............................................................ integer → integer*
  
  Number of columns to use for the output image.

  **Default value:** 1

  **Suggested values:** **NumColumns** ∈ {1, 2, 3, 4, 5, 6, 7}

  **Restriction:** **NumColumns** ≥ 1

- **TileOrder** *(input_control) ............................................................ string → string*
  
  Order of the input images in the output image.

  **Default value:** 'vertical'

  **List of values:** **TileOrder** ∈ {'horizontal', 'vertical'}

---

### Example

* Grab 5 (multi-channel) images and stack them vertically.

  ```
  gen_empty_obj (Images)
  for I := 1 to 5 by 1
    grab_image_async (ImageGrabbed, AcqHandle, -1)
    concat_obj (Images, ImageGrabbed, Images)
  endfor
  tile_images (Images, TiledImage, 1, 'vertical')
  ```

---

### Result

**tile_images** returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via **set_system( ::'no_object_result',<Result>::)**. If necessary, an exception is raised.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

---

### Possible Predecessors

**append_channel**

### Alternatives

**tile_channels, tile_images_offset**

### See also

**change_format, crop_part, crop_rectangle**

---

### Module

**Foundation**
Tile multiple image objects into a large image with explicit positioning information.

tile_images_offset tiles multiple input image objects, which must contain the same number of channels, into a large image. The input image object Images contains Num images, which may be of different size. The output image TiledImage contains as many channels as the input images. The size of the output image is determined by the parameters Width and Height. The position of the upper left corner of the input images in the output images is determined by the parameters OffsetRow and OffsetCol. Both parameters must contain exactly Num values. Optionally, each input image can be cropped to an arbitrary rectangle that is smaller than the input image. To do so, the parameters Row1, Col1, Row2, and Col2 must be set accordingly. If any of these four parameters is set to -1, the corresponding input image is not cropped. In any case, all four parameters must contain Num values. If the input images are cropped the position parameters OffsetRow and OffsetCol refer to the upper left corner of the cropped image. If the input images overlap each other in the output image (while taking into account their respective domains), the image with the higher index in Images overwrites the image data of the image with the lower index. The domain of TiledImage is obtained by copying the domains of Images to the corresponding locations in the output image.

Attention

If the input images all have the same size and tile the output image exactly, the operator tile_images usually will be slightly faster.

Parameters

- Images (input_object) ...... (multichannel-)image(-array) ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Input images.

- TiledImage (output_object) ...... (multichannel-)image ~ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
  Tiled output image.

- OffsetRow (input_control) ........................................ point.y(-array) ~ integer
  Row coordinate of the upper left corner of the input images in the output image.
  Default value: 0
  Suggested values: OffsetRow ∈ {0, 50, 100, 150, 200, 250}

- OffsetCol (input_control) ........................................ point.x(-array) ~ integer
  Column coordinate of the upper left corner of the input images in the output image.
  Default value: 0
  Suggested values: OffsetCol ∈ {0, 50, 100, 150, 200, 250}

- Row1 (input_control) ........................................ rectangle.origin.y(-array) ~ integer
  Row coordinate of the upper left corner of the copied part of the respective input image.
  Default value: -1
  Suggested values: Row1 ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}

- Col1 (input_control) ........................................ rectangle.origin.x(-array) ~ integer
  Column coordinate of the upper left corner of the copied part of the respective input image.
  Default value: -1
  Suggested values: Col1 ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}

- Row2 (input_control) ........................................ rectangle.corner.y(-array) ~ integer
  Row coordinate of the lower right corner of the copied part of the respective input image.
  Default value: -1
  Suggested values: Row2 ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}

- Col2 (input_control) ........................................ rectangle.corner.x(-array) ~ integer
  Column coordinate of the lower right corner of the copied part of the respective input image.
  Default value: -1
  Suggested values: Col2 ∈ {-1, 0, 10, 20, 50, 100, 200, 300, 500}

- Width (input_control) ........................................ extent.x ~ integer
  Width of the output image.
  Default value: 512
  Suggested values: Width ∈ {32, 64, 128, 256, 512, 768, 1024, 2048, 4096}
Manipulation

Height (input_control) 

Height of the output image.

Default value: 512

Suggested values: \( \text{Height} \in \{32, 64, 128, 256, 512, 525, 1024, 2048, 4096\} \)

---

Example 1

Grab 2 (multi-channel) NTSC images, crop the bottom 5 lines off
* of each image, the right 5 columns off of the first image, and
* the left five lines off of the second image, and put the cropped
* images side-by-side.

gen_empty_obj (Images)
for I := 1 to 2 by 1
   grab_image_async (ImageGrabbed, AcqHandle, -1)
   concat_obj (Images, ImageGrabbed, Images)
endfor
tile_images_offset (Images, TiledImage, [0,635], [0,0], [0,0], \[
   [0,5], [474,474], [634,639], 635, 950\])

---

Example 2

Enlarge image by 15 rows and columns on all sides

EnlargeColsBy := 15
EnlargeRowsBy := 15

g10_image_pointer1 (Image, Pointer, Type, WidthImage, HeightImage)
tile_images_offset (Image, EnlargedImage, EnlargeRowsBy, EnlargeColsBy, \[
   -1, -1, -1, -1, WidthImage + EnlargeColsBy*2, \[
   HeightImage + EnlargeRowsBy*2\])

---

Result

tile_images_offset returns 2 (H_MSG_TRUE) if all parameters are correct and no error oc-

curs during execution. If the input is empty the behavior can be set via set_system(::

‘no_object_result’,<Result>:). If necessary, an exception is raised.

---

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

15.8 Manipulation

overpaint_gray ( ImageDestination, ImageSource : : : )

Overpaint the gray values of an image.
overpaint_gray copies the gray values of the image given in ImageSource into the image in ImageDestination. Only the gray values of the domain of ImageSource are copied (see reduce_domain).

If you do not want to modify ImageDestination itself, you can use the operator paint_gray, which returns the result in a newly created image.

Attention
overpaint_gray modifies the content of an already existing image (ImageDestination). Besides, even other image objects may be affected: For example, if you created ImageDestination via copy_obj from another image object (or vice versa), overpaint_gray will also modify the image matrix of this other image object. Therefore, overpaint_gray should only be used to overpaint newly created image objects. Typical operators for this task are, e.g., gen_image_const (creates a new image with a specified size), gen_image_proto (creates an image with the size of a specified prototype image) or copy_image (creates an image as the copy of a specified image).

Parameters

- ImageDestination (input_object) ...... (multichannel-)image  \( \rightarrow \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  Input image to be painted over.

- ImageSource (input_object) ...... (multichannel-)image  \( \rightarrow \) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  Input image containing the desired gray values.

Example

* Copy a circular part of the image 'monkey' into a new image (New1):

  read_image(Image,'monkey')
  gen_circle(Circle,200,200,150)
  reduce_domain(Image,Circle,Mask)
  * New image with black (0) background
  gen_image_proto(Image,New1,0.0)
  * Copy a part of the image 'monkey' into New1
  overpaint_gray(New1,Mask)

Result

overpaint_gray returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ImageDestination

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

paint_region, overpaint_region

Module

Foundation

HALCON/HDevelop Reference Manual, 2020-11-10
**overpaint_region** ( Image, Region : : Grayval, Type : )

Overpaint regions in an image.

`overpaint_region` paints the regions given in `Region` with a constant gray value into the image given in `Image`. These gray values can either be specified for each channel once, valid for all regions, or for each region separately. To define the latter, group the channel gray values `g` of each region and concatenate them to a tuple according to the regions’ order, e.g., for a three channel image:

\[ g(\text{channel1},\text{region1}), g(\text{channel2},\text{region1}), g(\text{channel3},\text{region1}), g(\text{channel1},\text{region2}), \ldots \]

If the input image is of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. The parameter `Type` determines whether the region should be painted filled ('fill') or whether only its boundary should be painted ('margin').

If you do not want to modify `Image` itself, you can use the operator `paint_region`, which returns the result in a newly created image.

---

**Parameters**

- **Image** (input_object) ...... (multichannel-)image \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  - Image in which the regions are to be painted.

- **Region** (input_object) ........................................... region(-array) \(\sim\) object
  - Regions to be painted into the input image.

- **Grayval** (input_control) ...................................... number(-array) \(\sim\) real / integer
  - Desired gray values of the regions.
  - Default value: 255.0
  - Suggested values: `Grayval \in \{0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0\}

- **Type** (input_control) ............................................. string \(\sim\) string
  - Paint regions filled or as boundaries.
  - Default value: 'fill'
  - List of values: `Type \in \{'fill', 'margin'\}'

---

**Example**

* Paint a rectangle into a new image (New1)

```hcout
  gen_rectangle1(Rectangle, 100.0, 100.0, 300.0, 300.0)
  * generate a black image
  gen_image_const(New1, 'byte', 768, 576)
  * paint a white rectangle
  overpaint_region(New1, Rectangle, 255.0, 'fill')
```

**Result**

`overpaint_region` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system(\::\::'no_object_result', <Result>::)`. If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
Process without parallelization.

This operator modifies the state of the following input parameter:

- **Image**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**Possible Predecessors**

- read_image, gen_image_const, gen_image_proto, reduce_domain

---

**Alternatives**

- set_grayval, paint_region, paint_xld

---

**See also**

- reduce_domain, set_draw, paint_gray, overpaint_gray, gen_image_const

---

**Module**

**paint_gray** ( ImageSource, ImageDestination : MixedImage : : )

Paint the gray values of an image into another image.

**paint_gray** paints the gray values of the image given in **ImageSource** into the image in **ImageDestination** and returns the resulting image in **MixedImage**. Only the gray values of the domain of **ImageSource** are copied (see **reduce_domain**).

As an alternative to **paint_gray**, you can use the operator **overpaint_gray**, which directly paints the gray values into **ImageDestination**.

**Parameters**

- **ImageSource** (input_object) ...... (multichannel-)image $\rightarrow$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  - Input image containing the desired gray values.

- **ImageDestination** (input_object) ...... (multichannel-)image $\rightarrow$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  - Input image to be painted over.

- **MixedImage** (output_object) ...... image $\rightarrow$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
  - Result image.

**Example**

* Copy a circular part of the image 'monkey' into the image 'fabrik':

  ```
  read_image(Image,'monkey')
  gen_circle(Circle,200,200,150)
  reduce_domain(Image,Circle,Mask)
  read_image(Image2,'fabrik')
  paint_gray(Mask,Image2,MixedImage)
  ```

**Result**

**paint_gray** returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

paint_region, overpaint_region

Module

Paint regions into an image.

paint_region paints the regions given in Region with a constant gray value into the image given in Image and returns the result in ImageResult. These gray values can either be specified for each channel once, valid for all regions, or for each region separately. To define the latter, group the channel gray values \( g \) of each region and concatenate them to a tuple according to the regions’ order, e.g., for a three channel image:

\[
[g(channel1,region1), g(channel2,region1), g(channel3,region1), g(channel1,region2), ...]
\]

If the input image is of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. The parameter Type determines whether the region should be painted filled ('fill') or whether only its boundary should be painted ('margin').

As an alternative to paint_region, you can use the operator overpaint_region, which directly paints the regions into Image.

Parameters

- Region (input_object) ........................................ region(-array) \sim object
  Regions to be painted into the input image.
- Image (input_object) ...... (multichannel-)image \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image in which the regions are to be painted.
- ImageResult (output_object) ...... image \sim object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image containing the result.
- Grayval (input_control) ...................................... number(-array) \sim real / integer
  Desired gray values of the regions.
  Default value: 255.0
  Suggested values: Grayval \in \{0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0\}
- Type (input_control) ........................................ string \sim string
  Paint regions filled or as boundaries.
  Default value: 'fill'
  List of values: Type \in \{'fill', 'margin'\}

Example

* Paint a rectangle into the image 'monkey'

read_image(Image, 'monkey')
gen_rectangle1(Rectangle, 100.0, 100.0, 300.0, 300.0)
* paint a white rectangle
paint_region(Rectangle, Image, ImageResult, 255.0, 'fill')
Result

paint_region returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(;'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Alternatives

set_grayval, overpaint_region, paint_xld

See also

reduce_domain, paint_gray, overpaint_gray, set_draw, gen_image_const

Module

Foundation

Paint XLD objects into an image.

paint_xld paints the XLD objects XLD of type contour or polygon with the constant gray values Grayval into each channel of the background image given in Image and returns the result in ImageResult. Open contours of XLD objects are closed and their enclosed regions are filled up. The rim of the subpixel XLD objects is painted onto the background image using anti-aliasing.

Filling up XLD-objects that have crossings or segments that are very close (lying in neighboring pixels) does not work correctly and leads to artifacts. The set_system parameter ‘neighborhood’ defines whether diagonal neighbors are filled as well as orthogonal neighbors.

Grayval contains the gray values for painting the XLD objects. These gray values can either be specified for each channel once, valid for all XLD objects, or for each XLD object separately. To define the latter, group the channel gray values $g$ of each XLD object and concatenate them to a tuple according to the order of the XLD objects, e.g., for a three channel image:

$$[g(channel1,xld1), g(channel2,xld1), g(channel3,xld1), g(channel1,xld2), \ldots]$$

If the input image is of type ‘direction’, gray values that are not in the value range that is valid for ‘direction’ images are set to the value 255 to mark them as invalid.

Parameters

- **XLD (input_object)** ................................................................. xld(-array) \(\rightarrow\) object
  XLD objects to be painted into the input image.
- **Image (input_object)** ...... (multichannel-)image \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
  Image in which the xld objects are to be painted.
- **ImageResult (output_object) ...... image \(\sim\) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
  Image containing the result.
- **Grayval (input_control) ........................ number(-array) \(\rightarrow\) real / integer
  Desired gray value of the xld object.
  Default value: 255.0
  Suggested values: Grayval \(\in\) \{0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0\}
15.8. MANIPULATION

Example

* Paint colored xld objects into a gray image

* read and copy image to generate a three channel image
read_image(Image1,'green-dot')
copy_image(Image1,Image2)
copy_image(Image1,Image3)
compose3(Image1,Image2,Image3,Image)

* extract subpixel border
threshold_sub_pix(Image1,Border,128)

* select the circle and the arrows
select_obj(Border,circle,14)
select_obj(Border,arrows,16)
concat_obj(circle,arrows,green_dot)

* paint a green circle and white arrows (to paint all
* objects e.g. blue, pass [0,0,255] tuple for GrayVal)
paint_xld(green_dot,Image,ImageResult,[0,255,0,255,255,255])

Result

paint_xld returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(!:‘no_object_result’,<Result>):. If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

read_image,gen_image_const,gen_image_proto,gen_contour_polygon_xld,
threshold_sub_pix

Alternatives
set_grayval,paint_gray,paint_region

See also

gen_image_const

Module

set_grayval ( Image : : Row, Column, Grayval : )

Set single gray values in an image.

set_grayval sets the gray values of the input image Image at the positions (Row,Column) to the values specified by Grayval. If Image is a multi-channel image, you can either set a single gray value for a pixel and thus set it for all available channels, or you can set the gray values g for all channels individually by concatenating them within Grayval. For example, for a three-channel image three gray values (according to the order of the channels) are specified for each pixel:

\[ g(\text{channel0},\text{pixel0}), g(\text{channel1},\text{pixel0}), g(\text{channel2},\text{pixel0}), g(\text{channel0},\text{pixel1}), \ldots ] \]

Please note that for complex or vector field images, two gray values per pixel must be specified (per channel).

If the image is of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid.

Attention

The operator set_grayval produces quite some overhead. Typically, it is used to set single gray values of
an image. It is not suitable for programming image processing operations such as filters. In this case it is more useful to use the operator `get_image_pointer1` and to directly use the C or C++ interface for integrating own procedures.

Note also that `set_grayval` modifies the content of an already existing image (`Image`). Besides, even other image objects may be affected: For example, if you created `Image` via `copy_obj` from another image object, `set_grayval` will also modify the image matrix of this other image object. Therefore, `set_grayval` should only be used to overwrite newly created image objects.

---

**Parameters**

- **Image** (input_object) ... (multichannel-)image $\sim$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
  
  Image to be modified.

- **Row** (input_control) ................................................ point.y(-array) $\sim$ integer
  
  Row coordinates of the pixels to be modified.
  
  Default value: 0
  
  Suggested values: $\text{Row} \in \{0, 10, 50, 127, 255, 511\}$
  
  Typical range of values: $0 \leq \text{Row}$
  
  Restriction: $0 \leq \text{Row} \&\& \text{Row} < \text{height(Image)}$

- **Column** (input_control) ........................................... point.x(-array) $\sim$ integer
  
  Column coordinates of the pixels to be modified.
  
  Default value: 0
  
  Suggested values: $\text{Column} \in \{0, 10, 50, 127, 255, 511\}$
  
  Typical range of values: $0 \leq \text{Column}$
  
  Restriction: $0 \leq \text{Column} \&\& \text{Column} < \text{width(Image)}$

- **Grayval** (input_control) .......................................... grayval(-array) $\sim$ real / integer
  
  Gray values to be used.
  
  Default value: 255.0
  
  Suggested values: $\text{Grayval} \in \{0.0, 1.0, 10.0, 128.0, 255.0\}$

---

**Result**

`set_grayval` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system(::/no_object_result, <Result>):`. If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

15.9 Type Conversion

**complex_to_real** ( ImageComplex : ImageReal, ImageImaginary : : )

Convert a complex image into two real images.

complex_to_real converts a complex image ImageComplex into two real images ImageReal and ImageImaginary, which contain the real and imaginary part of the complex image.

**Parameters**

- **ImageComplex** (input_object) singlechannelimage(-array) object : complex
  Complex image.
- **ImageReal** (output_object) image(-array) object : real
  Real part.
- **ImageImaginary** (output_object) image(-array) object : real
  Imaginary part.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**See also**

real_to_complex

**Foundation**

**convert_image_type** ( Image : ImageConverted : NewType : )

Convert the type of an image.

convert_image_type converts images of an arbitrary type into an arbitrary new image type. If the conversion is done from a larger to a smaller gray value range (e.g., from 'int4' to 'byte'), too large or too small values are simply "clipped". If the result images are of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. It is therefore advisable to adapt the range of gray values by calling scale_image before calling this operator. For images of type complex, only the real part is converted. The imaginary part is ignored. This facilitates an efficient conversion of images that have been transformed back from the frequency domain. Such images always have an imaginary part of 0.

**Attention**

The conversion to the 'int8' image format is only available on 64 bit systems! If the source and destination image type are identical, no new image matrix is allocated.

**Parameters**

- **Image** (input_object) (multichannel-)image(-array) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Image whose image type is to be changed.
- **ImageConverted** (output_object) (multichannel-)image(-array) object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
  Converted image.
- **NewType** (input_control) string
  Desired image type (i.e., type of the gray values).
  Default value: 'byte'
  List of values: NewType ∈ {'int1', 'int2', 'uint2', 'int4', 'int8', 'byte', 'real', 'direction', 'cyclic', 'complex'}
Result

convert_image_type returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(‘no_object_result’,<Result>). If necessary, an exception is raised.

------------------- Execution Information -------------------

real_to_vector_field ( Row, Col : VectorField : Type : )

Convert two real-valued images into a vector field image.

real_to_vector_field converts two real-valued images Row and Col into a vector field image VectorField. The input images contain the vector components in the row and column direction, respectively. The semantic type of VectorField is set with Type.
15.9. TYPE CONVERSION

Parameters

- **Row** (input_object) .................. singlechannelimage(-array) \(\rightarrow\) object : real
  Vector component in the row direction.

- **Col** (input_object) .................. singlechannelimage(-array) \(\rightarrow\) object : real
  Vector component in the column direction.

- **VectorField** (output_object) .................. image(-array) \(\rightarrow\) object : vector_field
  Displacement vector field.

- **Type** (input_control) .................. string \(\rightarrow\) string
  Semantic kind of the vector field.
  Default value: 'vector_field_relative'
  List of values: Type \(\in\) {'vector_field_relative', 'vector_field_absolute'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Chapter 16

Inspection

16.1 Bead Inspection

apply_bead_inspection_model ( Image : LeftContour, RightContour, ErrorSegment : BeadInspectionModel : ErrorType )

Inspect beads in an image, as defined by the bead inspection model.

The operator apply_bead_inspection_model applies the bead inspection model BeadInspectionModel to the input Image. The output parameter ErrorSegment indicates the positions of detected errors. The parameter ErrorType indicates the type of the detected errors. For more details on the possible errors, refer to the parameters’ description and figures in create_bead_inspection_model. The value of 'ErrorType' can be:

'no bead': No bead could be detected at this position.

'incorrect position': The center of the bead found at this position is further away from the contour than allowed by PositionTolerance.

'too thin': The bead is thinner than allowed by TargetThickness and ThicknessTolerance.

'too thick': The bead is thicker than allowed by TargetThickness and ThicknessTolerance.

Values of the generic parameters set through create_bead_inspection_model or set_bead_inspection_param highly affect the inspection results of the same model. For more details on those parameters, please refer to create_bead_inspection_model.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Image</td>
<td>Image to apply bead inspection on.</td>
</tr>
<tr>
<td>LeftContour</td>
<td>The detected left contour of the beads.</td>
</tr>
<tr>
<td>RightContour</td>
<td>The detected right contour of the beads.</td>
</tr>
<tr>
<td>ErrorSegment</td>
<td>Detected error segments</td>
</tr>
<tr>
<td>BeadInspectionModel</td>
<td>Handle of the bead inspection model to be used.</td>
</tr>
<tr>
<td>ErrorType</td>
<td>Types of detected errors</td>
</tr>
</tbody>
</table>

Result

The operator apply_bead_inspection_model returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information
Multithreading type: reentrant (runs in parallel with non-exclusive operators).
Multithreading scope: global (may be called from any thread).
Processed without parallelization.

This operator modifies the state of the following input parameter:

- BeadInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

```
clear_bead_inspection_model ( : : BeadInspectionModel : )
```

Delete the bead inspection model and free the allocated memory.

The operator `clear_bead_inspection_model` deletes a bead inspection model that was created by `create_bead_inspection_model`. All memory used by the model is freed. The handle of the model is passed in `BeadInspectionModel`. It is invalid after the operator call.

- **Parameters**
  
  - `BeadInspectionModel` (input_control) .......................... `bead_inspection_model` ↼ `handle`
    Handle of the bead inspection model.

- **Result**
  The operator `clear_bead_inspection_model` returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred bead inspection model can be freed correctly. Otherwise, an exception will be raised.

- **Execution Information**
  
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

This operator modifies the state of the following input parameter:

- BeadInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
create_bead_inspection_model ( BeadContour : TargetThickness, ThicknessTolerance, PositionTolerance, Polarity, GenParamName, GenParamValue : BeadInspectionModel )

Create a model to inspect beads or adhesive in images.
create_bead_inspection_model creates a model to inspect beads or adhesive in images.

The basic principle of bead inspection

The bead inspection operators enable the user to define a reference contour that indicates the position and shape of a bead or adhesive on a certain product. Images of such products can then be inspected to verify that a bead or adhesive exists at the positions defined by the contour and that it is of acceptable thickness. The images must already be aligned with the given contour.

The operator create_bead_inspection_model returns a handle to the bead inspection model in BeadInspectionModel, which can later be used to perform other operations related to bead inspection. These operations include the modification of the bead inspection model parameters and performing the inspection on input images as defined by the model.

Providing the model contour

In order to inspect beads, a contour serving as the model for the bead must be provided in BeadContour. Such a contour can be generated, e.g., by using the operators gen_contour_polygon_xld or gen_contour_nurbs_xld. The contour must be defined to be aligned to the beads in the input images. To achieve this, the user can draw the XLD directly on a reference image in the graphics window (with draw_polygon or draw_nurbs). To inspect beads consisting of multiple parts, multiple models must be created.

Mandatory parameters

In order to inspect beads, the following parameters must be set:

**TargetThickness**: defines the optimal bead thickness in pixels.
**ThicknessTolerance**: defines the tolerance to the bead’s thickness in pixels. The bead is accepted if its thickness is within the range: \[\text{TargetThickness} - \text{ThicknessTolerance}, \text{TargetThickness} + \text{ThicknessTolerance}\]

**PositionTolerance**: defines the tolerance to the bead’s position in pixels. The ‘bead position’ is the center of the detected bead. The bead is accepted if the distance between its center and the contour’s position is less than the PositionTolerance.

**Polarity**: defines the polarity of the bead in the images to inspect. ‘light’ if the bead is lighter than its background, ‘dark’ otherwise.

**Edge extraction parameters**

Bead inspection relies on edge extraction to identify the edges of beads. Accordingly, correct initialization of the measure_pos parameters helps improve bead inspection results. In particular, the following 2 parameters are included as generic parameters in the bead inspection model:

- **'sigma’**: As defined in measure_pos, ‘sigma’ is the standard deviation of the Gaussian smoothing kernel. The value of ‘sigma’ depends on the quality of the images to be inspected, namely on the amount of noise. ‘sigma’ is set to 2.0 by default.
- **'threshold’**: As defined in measure_pos, ‘threshold’ sets the minimum edge amplitude to be extracted. Setting a higher value for ‘threshold’ helps to avoid the extraction of noise edges and select salient edges. ‘threshold’ cannot be less than 1 and is set to 30 by default.

The Measure Assistant can be used to find suitable values for these two parameters.

---

**Example**

* Read the image of the bead to be inspected.
  
  `read_image (Image, 'bead/adhesive_bead_01')`

* Define the reference path of the adhesive beads.

```plaintext
get_bead_inspection_param ( : : BeadInspectionModel, 
   GenParamName : GenParamValue )
```

*Get the value of a parameter in a specific bead inspection model.*

The operator `get_bead_inspection_param` is used to query the values of the different parameters of a bead inspection model. The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. All these parameters can be set and changed at any time with the operator `set_bead_inspection_param`. Multiple parameters can be queried with a single call to `get_bead_inspection_param`.

---

HALCON 20.11.0.0
The parameters that can be queried are 'target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma' and 'threshold'. Only the model’s contour cannot be queried. Refer to \texttt{set_bead_inspection_param} and \texttt{create_bead_inspection_model} for a detailed description of all supported parameters.

\begin{verbatim}
Parameters

\begin{itemize}
  \item BeadInspectionModel \( (\text{input\_control}) \) \( \cdots \) \( \text{bead\_inspection\_model} \sim \text{handle} \)
    Handle of the bead inspection model.
  \item GenParamName \( (\text{input\_control}) \) \( \cdots \) \( \text{attribute.name\_array} \sim \text{string} \)
    Name of the model parameter that is queried.
    Default value: 'target_thickness'
    List of values: GenParamName \( \in \) \{'target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma', 'threshold'\}
  \item GenParamValue \( (\text{output\_control}) \) \( \cdots \) \( \text{attribute.value\_array} \sim \text{integer / real / string} \)
    Value of the queried model parameter.
\end{itemize}

\end{verbatim}

\textbf{Result}

The operator \texttt{get_bead_inspection_param} returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

\section*{Execution Information}

\section*{Module}

\texttt{2D Metrology}

\begin{verbatim}
set_bead_inspection_param ( : : BeadInspectionModel, GenParamName, GenParamValue : )
\end{verbatim}

\textbf{Set parameters of the bead inspection model.}

The operator \texttt{set_bead_inspection_param} is used to set parameters of a bead inspection model in order to adapt it to a particular inspection task. All parameters except for the model’s contour can be set with this operator. A new bead inspection model should be used when a new contour is introduced. The current values of all parameters can be queried with the operator \texttt{get_bead_inspection_param}.

\section*{Parameters that can be set}

The following parameters are essential and inspection model specific. It is vital for the inspection’s success to identify accurate values for those parameters:

- 'target_thickness': sets the TargetThickness.
- 'thickness_tolerance': sets the ThicknessTolerance.
- 'position_tolerance': sets the PositionTolerance.
- 'polarity': sets the bead’s Polarity.
- 'sigma'
- 'threshold'

For more details, refer to the parameters’ description in \texttt{create_bead_inspection_model}.
16.2. OCV

---

**Parameters**

- **BeadInspectionModel** (input_control) .................................. bead_inspection_model ↦ handle
  Handle of the bead inspection model.

- **GenParamName** (input_control) .................................. attribute.name(-array) ↦ string
  Name of the model parameter that shall be adjusted for the specified bead inspection model.
  **Default value:** 'target_thickness'
  **List of values:** GenParamName ∈ ['target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma', 'threshold']

- **GenParamValue** (input_control) .................................. attribute.value(-array) ↦ string / integer / real
  Value of the model parameter that shall be adjusted for the specified bead inspection model.
  **Default value:** 40
  **Suggested values:** GenParamValue ∈ {40, 10, 15, 0.6, 1.0, 4.0, 5.0, 'light', 'dark'}

---

**Result**

The operator `set_bead_inspection_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

---

**Execution Information**

### 16.2 OCV

```c
close_ocv ( : : OCVHandle : )
```

Clear an OCV tool.

`close_ocv` closes an open OCV tool and frees the memory. The OCV tool has been created using `create_ocv_proj` or `read_ocv`. The handle is after this call no longer valid.

---

**Parameters**

- **OCVHandle** (input_control) .................................. ocv ↦ handle
  Handle of the OCV tool which has to be freed.

---

**Example**
read_ocv("ocv_file", &ocv_handle);
for (i=0; i<1000; i++)
{
    grab_image_async(&Image, fg_handle, -1);
    reduce_domain(Image, ROI, &Pattern);
    do_ocv_simple(Pattern, ocv_handle, "A",
                  "true", "true", "false", "true", 10,
                  &Quality);
}
close_ocv(ocv_handle);

--- Result ---
close_ocv returns 2 (H_MSG_TRUE), if the handle is valid. Otherwise, an exception is raised.

--- Execution Information ---

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• OCVHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

--- Possible Predecessors ---
read_ocv, create_ocv_proj

close_ocr

--- See also ---
Module

OCR/OCV

--- Parameters ---

create_ocv_proj ( : : PatternNames : OCVHandle )

Create a new OCV tool based on gray value projections.

create_ocv_proj creates a new OCV tool. This tool will be used to train good-patterns for the optical character verification. The training is done using the operator traind_ocv_proj. Thus traind_ocv_proj is normally called after create_ocv_proj.

The pattern comparison is based on the gray projections: For every training pattern the horizontal and vertical gray projections are calculated by summing up the gray values along the rows and columns inside the region of the pattern. This operation is applied to the training patterns and the test patterns. For the training patterns the result is stored inside the OCV tool to save runtime while comparing patterns. The OCV is done by comparing the corresponding projections. The Quality is the similarity of the projections.

Input for create_ocv_proj are the names of the patterns (PatternNames) which have to be trained. The number and the names can be chosen arbitrary. In most case only one pattern will be trained, thus only one name has to be specified. The names will be used when doing the OCV (do_ocv_simple). It is possible to specify more names than actually used. These might be trained later.

To close the OCV tool, i.e. to free the memory, the operator close_ocv is called.
Example

```c
create_ocv_proj("A", &ocv_handle);
draw_region(&ROI, window_handle);
reduce_domain(Image, ROI, &Sample);
traind_ocv_proj(Sample, ocv_handle, "A", "single");
```

Result

`create_ocv_proj` returns 2 (H_MSG_TRUE), if the parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`traind_ocv_proj`, `write_ocv`, `close_ocv`

Alternatives

`read_ocv`

See also

`create_ocr_class_box`

Module

OCR/OCV

```c
deserialize_ocv ( : : SerializedItemHandle : OCVHandle )
```

Deserialize a serialized OCV tool.

`deserialize_ocv` deserializes an OCV tool, that was serialized by `serialize_ocv` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCV tool is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCV tool with the handle `OCVHandle`. After deserializing the tool the training can be completed for those patterns which have not been trained so far. Otherwise, a pattern comparison can be applied directly by calling `do_ocv_simple`.

Parameters

- **SerializedItemHandle** (input_control) ................. serialized_item ~ handle
  Handle of the serialized item.
- **OCVHandle** (output_control) .......................... ocv ~ handle
  Handle of the OCV tool.

Result

If the parameters are valid, the operator `deserialize_ocv` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
CHAPTER 16  INSPECTION

Possible Predecessors
fread_serialized_item, receive_serialized_item, serialize_ocv

Possible Successors
do_ocv_simple, close_ocv

Module

OCR/OCV

do_ocv_simple ( Pattern : : OCVHandle, PatternName, AdaptPos, AdaptSize, AdaptAngle, AdaptGray, Threshold : Quality )

Verification of a pattern using an OCV tool.
do_ocv_simple evaluates the pattern in (Pattern). Before the evaluation the good-pattern has to be trained by using the operator traind_ocv_proj. Both patterns should have roughly the same (relative) extent and shape. To specify which of the trained patterns is used as reference its name is specified in PatternName. The next four parameters influence the automatic adaption: AdaptPos and AdaptSize refer to the geometry of the pattern. AdaptPos specifies whether a shift of the position will be adapted automatically. AdaptSize is used to adapt to changes in the size of the pattern. AdaptAngle is not implemented. The parameter AdaptGray controls the adaption to changes of the gray values. This comprises additive and multiplicative changes of the intensity.

The parameter Threshold specifies the minimum difference of the gray values to be treated as an error. In this case the percentage of wrong pixels is returned. If the value is below 0 the sum of all errors normalized with respect to the size is returned.

The result of the operator is the Quality of the pattern with a value between 0 and 1. The value 1 corresponds to a pattern with no faults. The value 0 corresponds to a very big fault.

Parameters

- Pattern (input_object) ........................................... singlechannelimage(-array) \(\leadsto\) object : byte
  Characters to be verified.
- OCVHandle (input_control) ........................................... ocv \(\leadsto\) handle
  Handle of the OCV tool.
- PatternName (input_control) ........................................... string(-array) \(\leadsto\) string
  Name of the character.
  Default value: 'a'
- AdaptPos (input_control) ........................................... string \(\leadsto\) string
  Adaption to vertical and horizontal translation.
  Default value: 'true'
  List of values: AdaptPos \(\in\) ['true', 'false']
- AdaptSize (input_control) ........................................... string \(\leadsto\) string
  Adaption to vertical and horizontal scaling of the size.
  Default value: 'true'
  List of values: AdaptSize \(\in\) ['true', 'false']
- AdaptAngle (input_control) ........................................... string \(\leadsto\) string
  Adaption to changes of the orientation (not implemented).
  Default value: 'false'
  List of values: AdaptAngle \(\in\) ['false']
- AdaptGray (input_control) ........................................... string \(\leadsto\) string
  Adaption to additive and scaling gray value changes.
  Default value: 'true'
  List of values: AdaptGray \(\in\) ['true', 'false']
- Threshold (input_control) ........................................... number \(\leadsto\) real
  Minimum difference between objects.
  Default value: 10
  Suggested values: Threshold \(\in\) [-1.0, 0.0, 1.0, 5.0, 10.0, 15.0, 20.0, 30.0, 40.0, 50.0, 60.0, 80.0, 100.0, 150.0]
16.2. OCV

Quality (output_control) ................................. real(-array) \sim real
Evaluation of the character.

Typical range of values: 0.0 \leq \text{Quality} \leq 1.0

do_ocv_simple returns 2 (H_MSG_TRUE), if the handle and the characters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Possible Successors

close_ocv

See also

create_ocv_proj

Module

OCR/OCV

---

**read_ocv** (: : FileName : OCVHandle )

Reading an OCV tool from file.

read_ocv reads an OCV tool from file. The tool will contain the same information that it contained when saving it with write_ocv. After reading the tool the training can be completed for those patterns which have not been trained so far. Otherwise a pattern comparison can be applied directly by calling do_ocv_simple.

As extension '.ocv' is used. If this extension is not given with the file name it will be added automatically.

Parameters

- **FileName** (input_control) ................................. filename.read \sim string
  Name of the file which has to be read.
  Default value: 'test_ocv'
  File extension: .ocv

- **OCVHandle** (output_control) ................................. ocv \sim handle
  Handle of read OCV tool.

Example

read_ocv("ocv_file", &ocv_handle);
for (i=0; i<1000; i++)
{
    grab_image_async(&Image, fg_handle, -1);
    reduce_domain(Image, ROI, &Pattern);
    do_ocv_simple(Pattern, ocv_handle, "A",
                  "true", "true", "false", "true", 10,
                  &Quality);
}

close_ocv(ocv_handle);

Result

read_ocv returns 2 (H_MSG_TRUE), if the file is correct. Otherwise, an exception is raised.

---
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Possible Predecessors
- write_ocv

### Possible Successors
- do_ocv_simple, close_ocv
- See also read_ocr

### Module
OCR/OCV

#### serialize_ocv

**Serialize an OCV tool.**

serialize_ocv serializes the data of an OCV tool (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocv is converted to a serialized item. The OCV tool is defined by the handle OCVHandle. The serialized OCV tool is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocv.

#### Parameters
- OCVHandle (input_control) : OCVHandle
  - Handle of the OCV tool.
- SerializedItemHandle (output_control) : SerializedItemHandle
  - Handle of the serialized item.

#### Result
If the parameters are valid, the operator serialize_ocv returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

#### Execution Information
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors
- traind_ocv_proj

### Possible Successors
- fwrite_serialized_item, send_serialized_item, deserialize_ocv

### Module
OCR/OCV

#### traind_ocv_proj

**Training of an OCV tool.**

traind_ocv_proj trains patterns for an OCV tool that has been created using the operators create_ocv_proj or read_ocv. For this training one or multiple patterns are provided to the system. Such a pattern consists of an image with a reduced domain (ROI) for the area of the pattern. Note that the pattern should
not only contain foreground pixels (e.g. dark pixels of a character) but also background pixels. This can be implemented e.g. by the smallest surrounding rectangle of the pattern. Without this context an evaluation of the pattern is not possible.

If more than one pattern has to be trained this can be achieved by multiple calls (one for each pattern) or by calling `traind_ocv_proj` once with all patterns and a tuple of the corresponding names. The result will be in both cases the same. However using multiple calls will normally result in a longer execution time than using one call with all patterns.

### Parameters

- **Pattern** (input_object) ........................................... singlechannelimage(-array) \(\sim\) object : byte
  Pattern to be trained.

- **OCVHandle** (input_control) ........................................... ocv \(\sim\) handle
  Handle of the OCV tool to be trained.

- **Name** (input_control) ........................................... string(-array) \(\sim\) string
  Name(s) of the object(s) to analyze.
  **Default value:** `a`

- **Mode** (input_control) ........................................... string \(\sim\) string
  Mode for training (only one mode implemented).
  **Default value:** `single`
  **List of values:** Mode \(\in\) `{single}`

### Example

```cpp
create_ocv_proj("A", &ocv_handle);
draw_region(&ROI, window_handle);
reduce_domain(Image, ROI, &Sample);
traind_ocv_proj(Sample, ocv_handle, "A", "single");
```

### Result

`traind_ocv_proj` returns \(2\) (H_MSG_TRUE), if the handle and the training pattern(s) are correct. Otherwise, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **OCVHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `write_ocr_trainf`
- `create_ocv_proj`
- `read_ocv`
- `threshold`
- `connection`
- `select_shape`

### Possible Successors

- `close_ocv`

### See also

### Module

OCR/OCV

---

```cpp
write_ocv ( : : OCVHandle, FileName : )
```

*Saving an OCV tool to file.*
write_ocv writes an OCV tool to file. This can be used to save the result of a training (traind_ocvProj). The whole information contained in the OCV tool is stored in the file. The file can be reloaded afterwards using the operator read_ocv.

As file extension `.ocv` is used. If this extension is not given with the file name, it will be added automatically.

```c
Parameters

\[\text{OCVHandle}(\text{input\_control}) \Rightarrow \text{ocv \sim handle}\]
Handle of the OCV tool to be written.

\[\text{FileName}(\text{input\_control}) \Rightarrow \text{filename.write \sim string}\]
Name of the file where the tool has to be saved.

Default value: `test_ocv'

File extension: `.ocv`
```
write_ocv returns 2 (H_MSG_TRUE), if the data is correct and the file can be written. Otherwise, an exception is raised.

```
Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
```

16.3 Structured Light

This chapter describes operators for using structured light.

Concept of Structured Light

The basic concept behind structured light is the display of known patterns onto a display or projector. The way those patterns appear in the scene after hitting surfaces helps to further analyze the surfaces.

To use structured light, a model must first be created using `create_structured_light_model`. The model type is specified in `ModelType`. Currently, only the model type `deflectometry` is supported. Deflectometry is the procedure of analyzing the reflections of known patterns from specular or semi-specular surfaces. In such a setup, for every pattern image projected on the screen, a camera image of the reflection is acquired. Deformations of the pattern in the camera image imply a defect on the specular surface.

In the following, the steps that are required to perform defect detection on specular surfaces are described briefly.

Create a structured light model: In the first step, a structured light model is created with

- `create_structured_light_model`

or read with

- `read_structured_light_model`.  

---

HALCON/HDevelop Reference Manual, 2020-11-10
Set the model parameters: The different structured light model parameters can then be set with `set_structured_light_model_param` or queried with `get_structured_light_model_param`. The pattern parameters 'pattern_width', 'pattern_height', 'pattern_orientation', and 'pattern_type' specify along with the stripe parameters 'min_stripe_width' and 'single_stripe_width' the specifications of the pattern images to be generated and projected onto the specular surface. Finally, the 'persistence' parameter can be enabled to debug intermediate results.

Generate the pattern images: The pattern images are to be generated with `gen_structured_light_pattern` after setting all relevant parameters. Please ensure that the output images are as needed in the particular setup.

Project the patterns and acquire the camera images: At this stage, the pattern images are shown on the display and reflected by the specular surface. The respective reflected image is acquired by the camera for each pattern image.

Decode the acquired images: The acquired CameraImages can be decoded with `decode_structured_light_pattern`. Upon calling this operator, the correspondence images are created and stored in the model StructuredLightModel.

Get the results: Now the decoded 'correspondence_image', as well as other results can be queried with `get_structured_light_object`. The 'defect_image' can be generated and queried with `get_structured_light_object`. For more details of the different objects that can be queried, please refer to the operator's documentation.

Further operators

The structured light model offers various other operators that help access and update the various parameters of the model.

The operator `write_structured_light_model` enables writing the structured light model to a file. Please note that previously generated pattern images are not written in this file. A structured light model file can be read using `read_structured_light_model`.

Furthermore, it is possible to serialize and deserialize the structured light model using `serialize_structured_light_model` and `deserialize_structured_light_model`.

Further Information

See also the “Solution Guide Basics” for further details.

```
clear_structured_light_model ( : : StructuredLightModel : )
```

Clear a structured light model and free the allocated memory.

The operator `clear_structured_light_model` deletes a structured light model that was created by `create_structured_light_model`. All memory used by the model is freed. The handle of the model is passed in StructuredLightModel. It is invalid after the operator call.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_structured_light_model

Module

3D Metrology

create_structured_light_model ( : ModelType : StructuredLightModel )

Create a structured light model.

create_structured_light_model creates a new structured light model of type ModelType. Currently, only the type 'deflectometry' is supported.

The parameters of the structured light model can be queried with get_structured_light_model_param and manipulated by calls to set_structured_light_model_param.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

Parameters

ModelType (input_control) string ~ string
The type of the created structured light model.

Default value: 'deflectometry'

StructuredLightModel (output_control)  structured_light_model ~ handle
Handle for using and accessing the structured light model.

Example

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)

* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)

* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)

Result

The operator create_structured_light_model returns the value 2 (H_MSG_TRUE) if the structured light model can be allocated correctly. Otherwise, an exception will be raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

• Multithreading scope: global (may be called from any thread).

• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_structured_light_model_param, get_structured_light_model_param

16.3. STRUCTURED LIGHT

```
decode_structured_light_pattern (  
    CameraImages : : StructuredLightModel : )  
```

Decode the camera images acquired with a structured light setup.

decode_structured_light_pattern decodes the camera images CameraImages that have been previously acquired with a structured light setup. The correspondence images and other intermediate results that are created by the decoding process are stored in the model StructuredLightModel and can be accessed afterwards using the operator get_structured_light_object.

In the following, the decoding process is explained in detail:

As mentioned in gen_structured_light_pattern the first purpose is to find out whether a pixel is in a region where a light stripe is reflected or where a dark stripe is reflected. To simplify this decision process the normalization images are used and a locally varying threshold is determined that is able to cope with objects of varying reflectance and lighting conditions. During the decoding of the acquired camera images all Gray code images are then compared with the previously calculated threshold. A pixel within the image is classified as bright if its gray value is greater or equal this threshold.

Furthermore, the pattern region is segmented during the decoding process. The segmentation is controlled by the parameter 'min_gray_difference' (see set_structured_light_model_param).

Assuming that n Gray code images have been processed, we get a n-bit binary code for each pixel. From this sequence the row and column coordinates up to 'min_stripe_width'/2 of the monitor can be derived.

If the StructuredLightModel is a hybrid system consisting not only of Gray code images but also of phase shift images (see gen_structured_light_pattern), the next step is to decode the latter ones. The result is a subpixel-precise correspondence image between the monitor coordinates and the camera coordinates that contains the information which camera pixel observes which monitor pixel.

If the 'pattern_type' of the StructuredLightModel is set to 'single_stripe', the first step in the decoding process is to decide which single stripe shed its light on a camera pixel. The Gray code sequence and phase are then used to refine the position within the found single stripe.

In real world setups it may occur that the detected Gray code sequence of a pixel is wrong. This can then lead to values in the correspondence images which represent monitor rows or columns larger than the monitor width and height. To avoid these problems, the last step of the decoding process is to remove these values from the correspondence images.

```
Parameters

▷ CameraImages (input_object) ......................... (multichannel-)image-array) ~ object : byte / uint2
Acquired camera images.
▷ StructuredLightModel (input_control) ................. structured_light_model ~ handle
Handle of the structured light model.
```

--- Example ---

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Set the size of the monitor
set_structured_light_model_param (StructuredLightModel, \n  'pattern_width', 1600)
set_structured_light_model_param (StructuredLightModel, \n  'pattern_height', 1200)
* Set the smallest width of the stripes in the pattern
set_structured_light_model_param (StructuredLightModel, \n  'min_stripe_width', 8)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Set the expected black/white contrast in the region of interest
set_structured_light_model_param (StructuredLightModel, \n  'min_gray_difference', 70)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the computed correspondences and defects
CHAPTER 16 INSPECTION

get_structured_light_object (CorrespondenceImages, StructuredLightModel, 'correspondence_image')

set_structured_light_model_param (StructuredLightModel, 'derivative_sigma', Sigma)

get_structured_light_object (DefectImage, StructuredLightModel, 'defect_image')

Result

The operator `decode_structured_light_pattern` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `StructuredLightModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- `gen_structured_light_pattern`

Possible Successors

- `create_structured_light_model`, `set_structured_light_model_param`

Module

3D Metrology

deserialize_structured_light_model (  
  : : SerializedItemHandle : StructuredLightModel )

Deserialize a structured light model.

deserialize_structured_light_model deserializes a structured light model that was serialized by `serialize_structured_light_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized structured light model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created structured light model with the handle `StructuredLightModel`.

Parameters

- `SerializedItemHandle` (input_control) .......................... serialized_item  ~ handle
  Handle of the serialized item.
- `StructuredLightModel` (output_control) ..................... structured_light_model  ~ handle
  Handle of the structured light model.

Example

* Deserialize the model
  deserialize_structured_light_model (SerializedItemHandle, \  StructuredLightModel)

* Get a previously decoded result
  get_structured_light_object (CorrespondenceImages, StructuredLightModel, \  'correspondence_image')
* Decode new camera images
  \n  `decode_structured_light_pattern (CameraImages, StructuredLightModel)`

* Get the decoded result
  \n  `get_structured_light_object (CorrespondenceImagesNew, StructuredLightModel, correlimage)`

**Result**

The operator `deserialize_structured_light_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Module**

3D Metrology

```haskell
gen_structured_light_pattern (: PatternImages : StructuredLightModel : )
```

Generate the pattern images to be displayed in a structured light setup.

`gen_structured_light_pattern` generates the pattern images that need to be displayed in a structured light setup. Several parameters such as the width and height of the images, the pattern type and the minimal stripe width need to be set in advance in the model `StructuredLightModel` using `set_structured_light_model_param`. Dependent on the set parameters of the `StructuredLightModel`, the number and the appearance of the pattern images vary.

In general, the pattern images can be divided into four groups of images:

- Normalization images
- Gray code images
- Phase shift images
- Single stripe images

**General information about the image types**

**Normalization images:**

Decoding of Gray code images relies upon being able to know whether a pixel is in a region where a light stripe is reflected or where a dark stripe is reflected. To allow a robust decoding even for large variations in the surface reflectance, normalization images are used to simplify the process of identifying light and dark regions. The simplest but in most cases also sufficient approach is to generate one entirely black and one entirely white image. During the decoding of the acquired camera images (see `decode_structured_light_pattern`) all Gray...
code images are then compared with the mean of the dark and the bright image and a pixel within the image is classified as bright if its gray value is greater or equal the previously calculated mean.

Another approach is to use the Gray code images as explained in the next section and generate an inverted version of these images. A pixel is then classified as light, if its gray value in the first image is brighter than the gray value of the inverted version.

**Gray code images:**

Before performing any practical task such as detecting defects, the first step in any structured light measurement process is to find a mapping between the pixel plane of the camera and the pixel plane of the monitor. This can be achieved by displaying a series of images that uniquely encode the rows and columns of the monitor. Since Gray code images have some advantages compared to other pattern types, they are typically used for the encoding. An example of a series of vertical and horizontal Gray code images can be seen in the subsequent figure.

![Image series of vertical and horizontal Gray code images](image)

Although using Gray code images is a very simple, yet suitable approach, it comes with certain limitations. One drawback is that often many Gray code images are required to achieve a spatial resolution sufficient for practical applications. However, with increasingly finer resolution of the stripes, a correct decoding becomes harder and harder because of blurring effects introduced by the optics involved in the measurement process. To overcome these limitations, the third group of pattern images (phase shift images) can be generated.

**Phase shift images:**

Phase shift images usually use periodic patterns such as sine or cosine waves to reconstruct the phase and in combination with Gray code images the correspondences between the monitor and the camera coordinates. To allow a decoding that is robust despite variations in the surface reflectance and has a relaxed noise influence, four phase shift images per orientation (vertical or horizontal) are generated. Each image is a cosine wave with phase shifts of $k\pi/2$, where $k = 0, \ldots, 3$.

![Image series of vertical and horizontal phase shift images](image)

The main advantage of using phase shift images, is that in contrast to Gray code images subpixel-precise correspondences between the monitor and the camera coordinates can be calculated. Since the images are periodic, the
16.3. STRUCTURED LIGHT

encoding is unique up to integer multiples of the period length. In order to achieve a unique encoding over the entire image, the combination with the Gray code image is necessary.

**Single stripe images:**

Single stripe images are dark with one bright stripe. The bright stripe is shifted over the images such that each monitor pixel is contained in exactly one stripe. To decide which bright stripe is reflected in the area observed by a camera pixel, the brightest pixel value within the sequence of single stripe images is chosen during decoding. This allows a decoding that is robust despite variations in the surface reflectance.

Image series of vertical and horizontal single stripe images as generated by `gen_structured_light_pattern` for `pattern_type` set to 'single_stripe'.

The Gray code sequence and phase are then used to refine the position within the found single stripe. Thus, while additional single stripe images are generated, the number of created Gray code images will typically decrease slightly.

Image series of vertical and horizontal Gray code images as generated by `gen_structured_light_pattern` for `pattern_type` set to 'single_stripe'.

**Information about the generation of the image types**

**Generating the normalization images:**

As mentioned above, HALCON offers two different kinds of normalization images. By default, the 'normalization' method is set to 'global' which results in the generation of an entirely black and an entirely white image. To change the method such that each Gray code is additionally inverted, `set_structured_light_model_param` has to be called using the method 'inverted_pattern'.

The main advantage of using a global normalization is that the number of images is significantly smaller while simultaneously providing satisfying results. Only in cases of partially specular surfaces, the other method might be more robust and should be chosen if the global normalization leads to wrong decoding results.

**Generating the Gray code images:**

The size, the number and the appearance of the Gray code images is dependent on the following parameters (see `set_structured_light_model_param`): 'pattern_width', 'pattern_height', 'min_stripe_width' and 'pattern_orientation'.
The first two parameters determine the size of the generated Gray code images and should usually be set to the size of the monitor that is used to display the pattern images. The parameter ‘min_stripe_width’ sets the width (in pixels) of the finest stripe of the pattern images that are generated. Additionally, all three parameters have a major influence on the number of created Gray code images.

Let \( \text{max}_\text{stripe}_\text{width} = 2^\lceil \log_2 (\text{pattern}_\text{width}) \rceil \) be the maximum stripe width in vertical direction and \( \text{max}_\text{stripe}_\text{width} = 2^\lceil \log_2 (\text{pattern}_\text{height}) \rceil \) be the maximum stripe width in horizontal direction. Then the number of Gray code images \( \text{num}_\text{images} \) with stripes oriented in one of the two directions (either horizontal or vertical) is given by

\[
\text{num}_\text{images} = \lceil \log_2 (2 \cdot \text{max}_\text{stripe}_\text{width}/\text{min}_\text{stripe}_\text{width}) \rceil
\]

The parameter ‘pattern_orientation’ sets the orientation of the Gray code (and phase shift) images that are generated. By default, images with vertical stripes as well as images with horizontal stripes are created. It is also possible to generate images with stripes having only one of the two directions. However, this is not recommended, because changes in the surface can then only be detected in one direction. Solely, if changes on the surface should be ignored or if defects are to be expected in only one direction, this parameter should be changed using `set_structured_light_model_param`.

Generating the phase shift images:

Since phase shift images are suitable to overcome the practical limitations of Gray code images their generation is recommended and enabled by default.

In case that the accuracy using Gray code images only is sufficient, the creation of phase shift images can be deactivated using `set_structured_light_model_param` by setting the ‘pattern_type’ to the value ‘gray_code’.

Generating the single stripe images:

In case that using Gray code and phase shift images only is not robust enough (this might happen, for example, on semi-specular surfaces), the creation of single stripe images can be activated using `set_structured_light_model_param` by setting the ‘pattern_type’ to the value ‘single_stripe’.

The number and the appearance of the single stripe images depends on the parameter ‘single_stripe_width’ which sets the width in pixels (see `set_structured_light_model_param`).

While additional single stripe images are generated, the number of created Gray code images will typically decrease slightly. To calculate the number of Gray code images, ‘max_stripe_width’ is replaced by ‘single_stripe_width’ in the formula above.

The use of these images is described in the introduction to the chapter Inspection / Structured Light.

---

**Parameters**

- **PatternImages** (output_object) ......................... (multichannel-)image-array \( \rightarrow \) object : byte
  Generated pattern images.

- **StructuredLightModel** (input_control) ......................... structured_light_model \( \rightarrow \) handle
  Handle of the structured light model.

---

**Example**

* Create the model
  `create_structured_light_model ('deflectometry', StructuredLightModel)`

* Set the size of the monitor
  `set_structured_light_model_param (StructuredLightModel, \n    'pattern_width', 1600)`
  `set_structured_light_model_param (StructuredLightModel, \n    'pattern_height', 1200)`

* Set the smallest width of the stripes in the pattern
  `set_structured_light_model_param (StructuredLightModel, \n    'min_stripe_width', 8)`

* Generate the patterns to project
  `gen_structured_light_pattern (PatternImages, StructuredLightModel)`

* Decode the camera images
  `decode_structured_light_pattern (CameraImages, StructuredLightModel)`
Result

The operator \texttt{gen\_structured\_light\_pattern} returns the value 2 (H\_MSG\_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

3D Metrology

\begin{verbatim}
get\_structured\_light\_model\_param ( : : StructuredLightModel, 
   GenParamName : GenParamValue )
\end{verbatim}

Query parameters of a structured light model.

The operator \texttt{get\_structured\_light\_model\_param} is used to query the values of the different parameters of a structured light model (StructuredLightModel). The names of the desired parameters are passed in the parameter \texttt{GenParamName}, the corresponding values are returned in \texttt{GenParamValue}. It is possible to query multiple parameters with a single call to \texttt{get\_structured\_light\_model\_param}. All parameters which can be manipulated by \texttt{set\_structured\_light\_model\_param} can be queried. Please refer to the documentation of \texttt{set\_structured\_light\_model\_param} for an explanation of the individual parameters.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter \texttt{Inspection / Structured Light}.

Parameters

- \texttt{StructuredLightModel} (input\_control) ....... \texttt{structured\_light\_model \rightarrow handle} Handle of the structured light model.
- \texttt{GenParamName} (input\_control) ................. \texttt{attribute\_name(-array) \rightarrow string} Name of the queried model parameter.
  - Default value: ‘min\_stripe\_width’
- \texttt{GenParamValue} (output\_control) .............. \texttt{attribute\_value(-array) \rightarrow integer / real / string} Value of the queried model parameter.

Example

* Create the model

create\_structured\_light\_model (‘deflectometry’, StructuredLightModel)

* Get the default value
get_structured_light_model_param (StructuredLightModel, \
    'min_stripe_width', Default)
* Set the value
set_structured_light_model_param (StructuredLightModel, \
    'min_stripe_width', 64)
* Get the value
get_structured_light_model_param (StructuredLightModel, 'min_stripe_width', \
    MinStripeWidth)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)

_________ Result
The operator get_structured_light_model_param returns the value 2 (H_MSG_TRUE) if the given
parameters are valid. Otherwise, an exception will be raised.

g**et_structured_light_object** ( : Object : StructuredLightModel,
ObjectName : )

Get (intermediate) iconic results of a structured light model.

With the operator get_structured_light_object you can access and inspect (intermediate) iconic results of a structured light measurement setup that has already been decoded using decode_structured_light_pattern.

On the one hand, this is useful to query the results of the decoding process ('correspondence_image') together with further processed results i.e. the defect image ('defect_image'). On the other hand, get_structured_light_object is also useful for troubleshooting the decoding process. Note that to collect the intermediate results, the 'persistence' mode has to be enabled for the StructuredLightModel (see set_structured_light_model_param) before decoding the model.

Objects that can be accessed without persistence mode enabled:

'correspondence_image': Image that describes the correspondences between the monitor and the camera. If the decoding has been performed in vertical and horizontal direction, both correspondence images are returned in an array. Otherwise, only the image of the appropriate direction is returned.

'pattern_region': Segmented region in which the camera images have been decoded. This region is identical to the domain of the correspondence images.

'defect_image': Image that describes possible defects on the surface which reflects the projected patterns towards the camera. Basically, high gray values in the defect image indicate that the gradients of the correspondence images differ significantly from gradients in the neighborhood.

Objects that can be accessed only when in persistence mode:

If the decoding has been performed in vertical and horizontal direction, images of both directions are returned in an array. Otherwise, only the images of the appropriate direction are returned.
'binarized_image': Images of the Gray code sequence where white and black gray values indicate that the camera pixel observed reflections of white or black regions of the projected patterns. If 'normalization' was set to 'inverted_pattern' using set_structured_light_model_param, this refers to the first image of an inverted pair.

'decoded_phase_shift_image': Decoded phase shift images containing the phase or angle corresponding to the projected phase images. One phase period covers stripes in the projected pattern of an extent 'min_stripe_width'.

decoded_single_stripe_image': Decoded single stripe image computed solely from the single stripe images. The correspondence image is a combination of this image with the Gray code and phase shift images, if 'pattern_type' is set to 'single_stripe'.

'gray_code_correspondence_image': Correspondence image computed solely from the Gray code images. If 'pattern_type' is set to 'gray_code_and_phase_shift', the actual correspondence image is a combination of this image with the decoded phase shift images. If 'pattern_type' is set to 'single_stripe', the actual correspondence image is a combination of this image with the decoded phase shift images and the decoded single stripe images.

--- Parameters ---

**Object** (output_object) .......................... (multichannel-)object(-array)  "object"
Iconic result.

**StructuredLightModel** (input_control) ........................ structured_light_model  "handle"
Handle of the structured light model.

**ObjectName** (input_control) ........................... string(-array)  "string"
Name of the iconic result to be returned.

**Default value:** correspondence_image

**Suggested values:** ObjectName ∈ {'correspondence_image', 'pattern_region',
'decoded_single_stripe_image', 'binarized_image', 'decoded_phase_shift_image',
'gray_code_correspondence_image', 'defect_image'}

--- Example ---

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the computed correspondences and defects
get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
'correspondence_image')
set_structured_light_model_param (StructuredLightModel, \
'derivative_sigma', Sigma)
get_structured_light_object (DefectImage, StructuredLightModel, \
'defect_image')

--- Result ---
The operator get_structured_light_object returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

--- Execution Information ---

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

gen_structured_light_pattern

Module

3D Metrology

```plaintext
read_structured_light_model ( :
  : : FileName : StructuredLightModel )
```

Read a structured light model from a file.

read_structured_light_model reads the structured light model StructuredLightModel that has been stored with write_structured_light_model. The default HALCON file extension for the structured light model is 'hslm'.

It can be helpful to write a model after setting all the optimal parameters for a particular setup. The model can be read later to easily regenerate pattern images. The objects already generated in the model before writing it can be also revisited later after reading the model.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

### Parameters

- **FileName** (input_control) : filename.read ~ string
  File name.
  File extension: .hslm

- **StructuredLightModel** (output_control) : structured_light_model ~ handle
  Handle of the structured light model.

### Example

* Read the model
  read_structured_light_model ('ExampleModel.hslm', StructuredLightModel)
* Get a previously decoded result
  get_structured_light_object (CorrespondenceImages, StructuredLightModel, 'correspondence_image')
* Decode new camera images
  decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the decoded result
  get_structured_light_object (CorrespondenceImagesNew, StructuredLightModel, 'correspondence_image')

### Result

The operator read_structured_light_model returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

serialize_structured_light_model ( : : StructuredLightModel : SerializedItemHandle )

Serialize a structured light model.

serialize_structured_light_model serializes a structured light model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The structured light model is defined by the handle StructuredLightModel. The serialized structured light model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_structured_light_model.

Parameters

- StructuredLightModel (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . structured_light_model ↼ handle
  Handle of the structured light model.
- SerializedItemHandle (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . serialized_item ↼ handle
  Handle of the serialized item.

Example

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Serialize the model
serialize_structured_light_model (StructuredLightModel, \ SerializedItemHandle)

Result

The operator serialize_structured_light_model returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

set_structured_light_model_param ( : : StructuredLightModel,
    GenParamName, GenParamValue : )

Set parameters of a structured light model.

The operator set_structured_light_model_param is used to manipulate the parameters of a structured light model StructuredLightModel. The current parameter settings can be queried with the operator get_structured_light_model_param.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

General parameters:
'persistence': Enables (GenParamValue='true') or disables (GenParamValue='false') the 'persistence' mode of the structured light model. When in persistence mode, the model stores intermediate results of the decoding, which can be inspected later by get_structured_light_object.

Note that the model might need significant memory space in this mode. Therefore, we recommend to enable this mode only during the setup and for debugging a structured light model setup.

If 'persistence' is changed, all results of the model are cleared.

Values: 'true', 'false', 1, 0
Default: 'false'

Parameters which influence the appearance of the generated pattern images:

'pattern_width': Sets the width of the pattern images that are generated while calling gen_structured_light_pattern. Usually, the value should be set to the width of the monitor that is used to display the pattern images.

The value of 'pattern_width' has to be larger than the value 'min_stripe_width'/2. In case that 'pattern_type' is 'single_stripe', it also has to be larger than 'single_stripe_width'/2.

If 'pattern_width' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 1
Default: 1024

'pattern_height': Sets the height of the pattern images that are generated while calling gen_structured_light_pattern. Usually, the value should be set to the height of the monitor that is used to display the pattern images.

The value of 'pattern_height' has to be larger than the value 'min_stripe_width'/2. In case that 'pattern_type' is 'single_stripe', it also has to be larger than 'single_stripe_width'/2.

If 'pattern_height' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 1
Default: 1024

'min_stripe_width': Sets the width (in pixels) of the finest stripe of the pattern images that are generated while calling gen_structured_light_pattern.

The value has to be a power of two. Furthermore, it has to be smaller or equal the minimum of the parameters 'pattern_width' and 'pattern_height' after rounding both up to their next power of two. In case that 'pattern_type' is 'single_stripe', it also has to be smaller or equal the 'single_stripe_width'.

If 'min_stripe_width' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: integer values larger or equal to 4 and a power of 2
Default: 32

'normalization': Sets the normalization mode of the structured light model. If the parameter is set to 'global', gen_structured_light_pattern generates two additional pattern images composed of a black and a white image. These images are then used in the decoding process to determine the actual pattern region. If instead, the value 'inverted_pattern' is chosen, each Gray code image is additionally inverted and the pattern region is segmented iteratively using the Gray code images and their inverted version.

If 'normalization' is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, gen_structured_light_pattern has to be called before decoding the model using decode_structured_light_pattern.

Values: 'global', 'inverted_pattern'
Default: 'global'

'pattern_orientation': Sets the orientation of the pattern images that are generated while calling gen_structured_light_pattern. If the parameter is set to 'both', pattern images with vertical stripes as well as pattern images with horizontal stripes are created. For 'vertical' the pattern images consist of vertical stripes only, whereas for 'horizontal' only horizontal stripes are generated.
If `pattern_orientation` is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: `both`, `vertical`, `horizontal`
Default: `both`

`pattern_type`: Sets the type of the pattern images that are generated while calling `gen_structured_light_pattern`.

<table>
<thead>
<tr>
<th><code>pattern_type</code></th>
<th>Generated Images</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gray_code</code></td>
<td>Gray code images</td>
</tr>
<tr>
<td><code>gray_code_and_phase_shift</code></td>
<td>Gray code images and phase shift images</td>
</tr>
<tr>
<td><code>single_stripe</code></td>
<td>Single stripe images, Gray code images and phase shift images</td>
</tr>
</tbody>
</table>

Usually, `gray_code_and_phase_shift` leads to more accurate results than `gray_code` because the combination between Gray code and phase images yields sub-pixel precise monitor coordinates. `single_stripe` can increase robustness in case of only partially specular surfaces.

If `pattern_type` is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: `gray_code_and_phase_shift`, `gray_code`, `single_stripe`
Default: `gray_code_and_phase_shift`

`single_stripe_width`: Sets the width (in pixels) of the single stripe that is generated while calling `gen_structured_light_pattern` using the `pattern_type` `single_stripe`.

The value has to be a power of two and has to be greater or equal `min_stripe_width`. Furthermore, it has to be smaller or equal the minimum of the parameters `pattern_width` and `pattern_height` after rounding both up to their next power of two.

Note that `single_stripe_width` can only be set in case that `pattern_type` is `single_stripe`. When `pattern_type` is changed to `single_stripe`, `single_stripe_width` is set to some power of two roughly halfway between the currently set `min_stripe_width` and the minimum of `pattern_width` and `pattern_height`.

If `single_stripe_width` is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: integer values larger or equal to 4 and a power of 2
Default: power of two roughly halfway between the currently set `min_stripe_width` and `pattern_width`, `pattern_height`

Parameters which influence the segmentation of the pattern region:

`min_gray_difference`: Sets the minimum gray value difference for the Gray code images. This value is used within `decode_structured_light_pattern` to determine the binarized images. Thereby, for each pixel of the camera images the gray value difference between the lighted and the unlighted case is calculated.

If the gray value difference of a pixel is smaller than `min_gray_difference`, it is excluded from the domain of the binarized images (see `get_structured_light_object`) and thus also from further calculations.

If `min_gray_difference` is set to the value 0, the segmented region is identical to the input region of the camera images with the only exception that pixels with a decoding result outside the pattern images are excluded.

Values: integer values larger or equal to 0
Default: 30

Parameters which influence the defect image:

`derivative_sigma`: Sets the sigma of the Gaussian (i.e. the amount of smoothing) that is used for the convolution of the correspondence image(s) to calculate the defect image.

Values: float or integer value larger or equal 0.01
Default: 2
Parameters

- **StructuredLightModel** (input_control) .......................... structured_light_model  \sim \ handle
  Handle of the structured light model.

- **GenParamName** (input_control) .......................... attribute.name(-array)  \sim \ string
  Name of the model parameter to be adjusted.
  **Default value**: ’min_stripe_width’
  **List of values**: GenParamName \in \ {'derivative_sigma’, ‘min_gray_difference’, ‘min_stripe_width’,
  ‘pattern_width’, ‘single_stripe_width’, ‘persistence’}

- **GenParamValue** (input_control) .......................... attribute.value(-array)  \sim \ integer / real / string
  New value of the model parameter.
  **Default value**: 32
  **Suggested values**: GenParamValue \in \ {0, 0.01, 0.5, 0.7, 1, 1.4, 5, 50.0, 64, 128, 256, 1024, ‘true’, ‘false’,
  ‘single_stripe’}

---

**Example**

* Create the model
  create_structured_light_model (’deflectometry’, StructuredLightModel)

* Set the size of the monitor
  set_structured_light_model_param (StructuredLightModel, ‘pattern_width’, 1600)
  set_structured_light_model_param (StructuredLightModel, ‘pattern_height’, 1200)

* Set the smallest width of the stripes in the pattern
  set_structured_light_model_param (StructuredLightModel, ‘min_stripe_width’, 8)

* Generate the patterns to project
  gen_structured_light_pattern (PatternImages, StructuredLightModel)

* Set the expected black/white contrast in the region of interest
  set_structured_light_model_param (StructuredLightModel, ‘min_gray_difference’, 70)

* Decode the camera images
  decode_structured_light_pattern (CameraImages, StructuredLightModel)

* Get the computed correspondences and defects
  get_structured_light_object (CorrespondenceImages, StructuredLightModel, ‘correspondence_image’)
  get_structured_light_object (DefectImage, StructuredLightModel, ‘defect_image’)

---

**Result**

The operator set_structured_light_model_param returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **StructuredLightModel**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
16.3. STRUCTURED LIGHT

write_structured_light_model ( : : StructuredLightModel, FileName : )

Write a structured light model to a file.

write_structured_light_model writes the structured light model StructuredLightModel to the file given by FileName. The default HALCON file extension for the structured light model is 'hslm'. The structured light model can be then read with read_structured_light_model. It should be noted that write_structured_light_model does not write any previously generated pattern images in the structured light model. In other words, only the parameters of the model and objects that were already generated will be written in the file. The list of structured light objects and how to generate each can be found in get_structured_light_object.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter Inspection / Structured Light.

--- Parameters ---

▷ StructuredLightModel (input_control) structed_light_model handle
Handle of the structured light model.

▷ FileName (input_control) file name.
File name. File extension: .hslm

--- Example ---

* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Write the model
write_structured_light_model (StructuredLightModel, 'ExampleModel.hslm')

--- Result ---

The operator write_structured_light_model returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

--- Execution Information ---

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

--- Possible Successors ---

3D Metrology
16.4 Texture Inspection

This chapter describes the operators for texture inspection.

Concept of the texture inspection model

The texture inspection model enables the inspection of textured surfaces with only having to set few parameters. The algorithm requires images of flawless texture for training. The training process extracts texture features from the training images and trains a texture inspection model that is based on Gaussian Mixture Model (GMM) classifiers. After a successful training, texture images can be compared to the texture inspection model and potential defects can be identified. Texture inspection works on image pyramids. This way, multiple frequency ranges of the texture are analyzed.

It is possible to use multi-channel images in the texture inspection pipeline.

In the following, the steps that are required to perform the texture inspection are described briefly.

Create a texture inspection model: In a first step, a texture inspection model is created with

- `create_texture_inspection_model`

or read with

- `read_texture_inspection_model`.

Add training samples: The operator

- `add_texture_inspection_model_image`

adds sample images to the texture inspection model.

![Image of a textured surface that is used to train a texture inspection model.](image)

Images that have been added to the texture inspection model with the help of `add_texture_inspection_model_image` can be viewed with `get_texture_inspection_model_image`. If all or a part of the added images are not needed for the current texture inspection, they can be removed from the model using `remove_texture_inspection_model_image`.

Train a texture inspection model: The texture inspection model is trained with

- `train_texture_inspection_model`.

In the training process an image pyramid is created. For each pyramid level a Gaussian Mixture Model (GMM) is trained and a ‘novelty_threshold’ is determined. The ‘novelty_threshold’ helps to distinguish between flawless and defective texture. After the training, it is possible to query the novelty thresholds with `get_texture_inspection_model_param`.

Several parameters influence the training. They can be set with
• **set_texture_inspection_model_param**.

We recommend the following proceeding for the training:

• Set initial parameters for the training, if needed:

  – `'patch_normalization'`: Setting this parameter to 'weber', the features of the used texture patches are normalized making the texture inspection model more robust against illumination changes. Note, however, that sometimes a normalization might not be desired, e.g., if the brightness is needed to discriminate between flawless and defective parts. In that case, a controlled illumination is absolutely necessary for a successful classification.

  – `'patch_rotational_robustness'`: Setting this parameter to 'true', the features of the used texture patches are sorted in a way that is robust against rotational changes. This can be used if it is difficult to train all possible orientations of the textured surface via training samples.

• Train the texture inspection model (using the default parameters): The initial training of the texture inspection model may be very time consuming, depending on the number of training images and their resolution. The following time saving strategies can be considered:

  – Zoom the images: Often, the texture inspection works even better on low resolution images. If it is known that the full resolution of the images is not needed, you can significantly reduce the training time by zooming the images. Zooming the image down by a factor of 2, e.g., reduces the training time by factor 4.

  – Accelerate the training: Another, but more risky strategy is to increase the threshold for the stopping criterion of the classifier optimization by setting the parameter `'gmm_em_threshold'`, e.g., from 0.001 to 0.1. This leads to shorter training times but also to a possibly less accurate texture inspection model. If this strategy is used, we strongly recommend to reduce `'gmm_em_threshold'` again after most of the parameters have been adjusted.

• Check the result of the training: Use a set of images with defective textures, classify them with the trained texture inspection model and check the results as is described for the step 'Apply the texture inspection model'. If the results are not satisfying, further parameters can be adjusted for the training. The most important parameters are:

  – `'num_levels'` or `'levels'`: The number of used pyramid levels or the explicitly used pyramid levels. Higher pyramid levels work on coarser texture features. If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then runtime can be reduced by setting the pyramid levels of interest explicitly with `'levels'`. If for example the `'levels'` are set to [1,3], the training and the texture classification are only performed on the first and third level.

  – `'sensitivity'`: Controls how strict the novelty thresholds are set. This way, the sensitivity to novelties can be adjusted. In general, positive values lead to fewer detected defects and negative values lead to less detected defects.

  – `'novelty_threshold'`: Sets the novelty threshold manually. This can be used for fine tuning if the results of the automatic estimation are not optimal.

• Repeat the training, if needed: If parameters were adjusted, usually the texture inspection model has to be retrained.

**Apply the texture inspection model:** After successfully training the texture inspection model it can be used to classify textured surfaces. Each test image can be compared to the texture inspection model with

• **apply_texture_inspection_model**.
For each test image the operator returns a 'novelty_region', which indicates where the image has high deviations to the trained texture samples. The 'novelty_region' is generated by combining the novelty regions of the different pyramid levels. The novelty regions of adjacent levels in the image pyramid are intersected with each other. This step helps to improve the robustness towards noise within the single pyramid level responses. The intersected novelty regions are then added to the returned 'novelty_region'. If a pyramid level has no adjacent pyramid level, the region itself is added to the 'novelty_region'. If, for example, 'num_levels' is set to 1, no adjacent pyramid level exists and the 'novelty_region' is the novelty region of the first pyramid level.

For debugging, the parameter 'gen_result_handle' can be set to 'true' with set_texture_inspection_model_param. This way, the novelty score images and novelty regions of the individual pyramid levels are stored in a result handle. They can then be read with

- get_texture_inspection_result_object.

In general, the novelty score images describe how well each pixel fits to the texture inspection model that was created within the training process. The novelty regions of the single pyramid levels are then calculated by applying the 'novelty_threshold' to the corresponding novelty score images.

Inspecting the novelty score images and the novelty regions provides you with hints which kinds of errors are detectable on which pyramid levels. Thus, you can decide whether parameters for the training and the classification should be adjusted, e.g., whether it is reasonable to explicitly select only a subset of pyramid levels using the parameter 'levels'.

The resulting 'novelty_score_image' (1) and the resulting 'novelty_region' (2) for the test image above.
Further operators

The functionality of the texture inspection can be altered by various parameters. The parameters can be queried with `get_texture_inspection_model_param` and altered with calls to `set_texture_inspection_model_param`.

It is possible to write a texture inspection model to file with the operator `write_texture_inspection_model`. Thereby, only the texture inspection model is stored. The images which were possibly added can be queried with the help of `get_texture_inspection_model_image` and stored separately by calling `write_object`.

To help reduce the memory required by the texture inspection model, it is possible to delete previously added images from the model with `remove_texture_inspection_model_image`.

Furthermore, it is possible to serialize and deserialize the texture inspection model with `serialize_texture_inspection_model` and `deserialize_texture_inspection_model`.

Glossary

In the following, the most important terms that are used in the context of texture inspection are described:

- **Training images** Images that are used for training.
- **Test images** Images which are compared to the trained texture inspection model.
- **Patch** A collection of neighboring pixels.
- **Texture feature** The pixel values within a patch.
- **Sample** A texture feature that is used for training.
- **Novelty Score** In the test process the texture features of the test images are compared to the texture inspection model and their 'novelty score' is calculated. The larger this value, the more probable it is that the individual texture feature does not fit to the texture inspection model.
- **Novelty Threshold** The novelty threshold is determined during the training process. Texture features with a novelty score below the novelty threshold fit to the texture inspection model. Texture features with a higher novelty score do not.

```plaintext
add_texture_inspection_model_image
Image : : TextureInspectionModel : Indices
```

*Add training images to the texture inspection model.*

`add_texture_inspection_model_image` adds training images to the texture inspection model (`TextureInspectionModel`). The domain of the training images is considered in all further calculations. Since the feature extraction considers a certain neighborhood of each pixel, no features can be extracted for pixels at the border of the domain. The border size (Border) depends on the 'patch_size' and computes to

$$\text{Border} = \frac{\text{patch\_size}}{2} - 1.$$  

All images which are added to the texture inspection model are used within the training process (see `train_texture_inspection_model` for more information). Furthermore, it is possible to query all of the images passed to the texture inspection model with `get_texture_inspection_model_image`.

Every added image receives an index (`Indices`), which allows the user to generate an assignment between the added images and his image data. By calls of `remove_texture_inspection_model_image`, the index can further be used to delete images from the model that are not needed anymore.

It is possible to add either gray-scale images or multichannel images. However, all of the passed images should have the same number of channels.

For an explanation of the concept of the texture inspection see the introduction of chapter *Inspection / Texture Inspection*.
**Parameters**

- **Image** (input_object) .............................. (multichannel-image-array) \( \sim \) object : byte / uint2 / real
  Image of flawless texture.
- **TextureInspectionModel** (input_control) ........................ texture_inspection_model \( \sim \) handle
  Handle of the texture inspection model.
- **Indices** (output_control) ............................. integer-array \( \sim \) integer
  Indices of the images that have been added to the texture inspection model.

---

**Example**

* Create texture inspection model
  
est_create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
  
  * Read and add training images
    
est_read_image (TrainImage, 'carpet/carpet_01')
    
est_add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \  
        Indices)
  
  * Train the model
    
est_train_texture_inspection_model (TextureInspectionModel)
  
  * Read and apply a test image
    
est_read_image (TrainImage, 'carpet/carpet_02')
    
est_apply_texture_inspection_model (TestImage, DefectCandidates, \  
        TextureInspectionModel, \  
        TextureInspectionResultID)

---

**Result**

The operator `add_texture_inspection_model_image` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- **TextureInspectionModel**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**Possible Predecessors**

- `create_texture_inspection_model`
- `set_texture_inspection_model_param`
- `get_texture_inspection_model_param`

---

**Possible Successors**

- `train_texture_inspection_model`
- `clear_texture_inspection_model`
- `remove_texture_inspection_model_image`
- `get_texture_inspection_model_image`

---

**Module**

- `apply_texture_inspection_model`

**apply_texture_inspection_model** (Image : NoveltyRegion :  
  TextureInspectionModel : TextureInspectionResultID)

*Inspection of the texture within an image.*
The operator `apply_texture_inspection_model` compares `Image` with the trained texture inspection model `TextureInspectionModel`. `Image` can either be a single image or a tuple of images. It is possible to pass either gray-scale or multichannel images. Hereby, the operator expects that the passed `Image` has the same number of channels than the model was trained with. The runtime of the `apply_texture_inspection_model` scales roughly linearly with the number of image channels. However, models using colored images are generally better at detecting colored texture defects.

Pixels that do not fit to the texture inspection model are returned in `NoveltyRegion`. Furthermore, if `gen_result_handle` has been set to `true` with `set_texture_inspection_model_param`, the operator also returns the result handle `TextureInspectionResultID` with more detailed information on the texture classification. If `gen_result_handle` is set to `false`, `TextureInspectionResultID` is empty.

For an explanation of the concept of the texture inspection see the introduction of chapter `Inspection / Texture Inspection`.

For each pyramid level texture features are extracted and classified with the corresponding GMM classifier. The resulting novelty score is then compared to the novelty threshold of the current pyramid level and classified as defective or not. The defective pixels are collected in a novelty region for each pyramid level. These novelty regions are then combined to the final novelty region returned in `NoveltyRegion`. The novelty regions of adjacent levels in the image pyramid are intersected with each other. This step helps to improve the robustness towards noise within the single pyramid level responses. The intersected novelty regions are then added to the returned `novelty_region`. If a pyramid level has no adjacent pyramid level the region itself is added to the `novelty_region`. If, for example, `num_levels` is set to 1, no adjacent pyramid level exists and the `novelty_region` is the novelty region of the first pyramid level.

If `gen_result_handle` is set to `true`, the result handle `TextureInspectionResultID` contains novelty score images and the resulting novelty regions for each pyramid level.

This information is useful for debugging and fine tuning of the model parameters (e.g., the novelty thresholds) and can be accessed with `get_texture_inspection_result_object`.

---

**Parameters**

- `Image` (input_object) .............................................. (multichannel-image-array \* object: byte / uint2 / real Image of the texture to be inspected.
- `NoveltyRegion` (output_object) .............................................. region-array \* object Novelty regions.
- `TextureInspectionModel` (input_control) ......................... texture_inspection_model \* handle Handle of the texture inspection model.
- `TextureInspectionResultID` (output_control) .................... texture_inspection_result \* handle Handle of the inspection results.

---

**Example**

* Create texture inspection model
  `create_texture_inspection_model ('basic', TextureInspectionModel)`
* Set parameters
  `set_texture_inspection_model_param (TextureInspectionModel, \\ 'gen_result_handle', 'true')`
* Make this short example fast:
  `set_texture_inspection_model_param (TextureInspectionModel, \\ 'gmm_em_max_iter', 1)`
* Read and add training images
  `read_image (TrainImage, 'carpet/carpet_01')`
  `add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \\ Indices)`
* Train the model
  `train_texture_inspection_model (TextureInspectionModel)`
* Read and apply a test image
  `read_image (TestImage, 'carpet/carpet_02')`
  `apply_texture_inspection_model (TestImage, DefectCandidates, \\ TextureInspectionModel, \\ TextureInspectionResultID)`
The operator `apply_texture_inspection_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- TextureInspectionResultID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `train_texture_inspection_model`

### Possible Successors

- `get_texture_inspection_result_object`, `get_texture_inspection_model_param`, `clear_texture_inspection_result`, `clear_texture_inspection_model`

### Module

`clear_texture_inspection_model { : : TextureInspectionModel : }`

Clear a texture inspection model and free the allocated memory.

The operator `clear_texture_inspection_model` deletes a texture inspection model that was created by `create_texture_inspection_model`. All memory used by the model is freed. The handle of the model is passed in `TextureInspectionModel`. It is invalid after the operator call.

For an explanation of the concept of the texture inspection see the introduction of chapter **Inspection / Texture Inspection**.

### Parameters

- **TextureInspectionModel** (input_control) texture_inspection_model(-array) ~ handle
  Handle of the texture inspection model.

### Example

* Create texture inspection model
  create_texture_inspection_model ('basic', TextureInspectionModel)
* Read and add training images
  read_image (TrainImage, 'carpet/carpet_01')
  add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)
* Train the model
  train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
  read_image (TestImage, 'carpet/carpet_02')
  apply_texture_inspection_model (TestImage, DefectCandidates, TextureInspectionModel, TextureInspectionResultID)
Result
The operator `clear_texture_inspection_model` returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred texture inspection model can be freed correctly. Otherwise, an exception will be raised.

Execution Information
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:
- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

See also
- `create_texture_inspection_model` Module

Matching

```plaintext
clear_texture_inspection_result ( 
  : : TextureInspectionResultID : )
```

Clear a texture inspection result handle and free the allocated memory.

The operator `clear_texture_inspection_result` clears the texture inspection result `TextureInspectionResultID` that was created by `apply_texture_inspection_model`. All memory used by the model is freed. The handle of the model is invalid after the operator call.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters
- `TextureInspectionResultID` (input_control) . . . . . . . . . . . . . texture_inspection_result(-array) ~ handle
  Handle of the texture inspection results.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \ 'gmm_em_max_iter', 1)
* Set parameter to generate a result handle
set_texture_inspection_model_param (TextureInspectionModel, \ 'gen_result_handle', 'true')
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \ Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \ TextureInspectionModel, \ TextureInspectionResultID)
```
The operator `clear_texture_inspection_result` returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred texture inspection model can be freed correctly. Otherwise, an exception will be raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TextureInspectionResultID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `apply_texture_inspection_model`

### Module

#### `create_texture_inspection_model`

Create a texture inspection model.

`create_texture_inspection_model` creates a new texture inspection model of type `ModelType`. Currently, only the model type `basic` is supported.

The parameters of the texture inspection can be queried with `get_texture_inspection_model_param` and manipulated by calls to `set_texture_inspection_model_param`.

For an explanation of the concept of the texture inspection see the introduction of chapter **Inspection / Texture Inspection**.

### Parameters

- **ModelType** (input_control) .......................... string ~ string
  - The type of the created texture inspection model.
  - Default value: `basic`
  - List of values: `ModelType ∈ ['basic']`

- **TextureInspectionModel** (output_control) ................. texture_inspection_model ~ handle
  - Handle for using and accessing the texture inspection model.

### Example

* Create texture inspection model
  
  ```
  create_texture_inspection_model ('basic', TextureInspectionModel)
  ```

* Make this short example fast:
  
  ```
  set_texture_inspection_model_param (TextureInspectionModel, \  
    'gmm_em_max_iter', 1)
  ```

* Read and add training images
  
  ```
  read_image (TrainImage, 'carpet/carpet_01')
  add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \  
    Indices)
  ```

* Train the model
  
  ```
  train_texture_inspection_model (TextureInspectionModel)
  ```

* Read and apply a test image
  
  ```
  read_image (TestImage, 'carpet/carpet_02')
  apply_texture_inspection_model (TestImage, DefectCandidates, \  
    TextureInspectionModel, \  
    TextureInspectionResultID)
  ```
16.4. TEXTURE INSPECTION

The operator `create_texture_inspection_model` returns the value 2 (H_MSG_TRUE) in the texture inspection model can be allocated correctly. Otherwise, an exception will be raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

---

**Possible Successors**

- `set_texture_inspection_model_param`
- `get_texture_inspection_model_param`
- `add_texture_inspection_model_image`

---

**Module**

```
deserialize_texture_inspection_model (:
    : SerializedItemHandle : TextureInspectionModel )
```

Deserialize a serialized texture inspection model.

`deserialize_texture_inspection_model` deserializes a texture inspection model, that was serialized by `serialize_texture_inspection_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized texture inspection model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created texture inspection model with the handle `TextureInspectionModel`.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

---

**Parameters**

- `SerializedItemHandle` (input_control) .............................. serialized_item ~ handle
  Handle of the serialized item.
- `TextureInspectionModel` (output_control) ......................... texture_inspection_model ~ handle
  Handle of the texture inspection model.

---

**Example**

* Create texture inspection model
`create_texture_inspection_model ('basic', TextureInspectionModel)`
* Set parameters
`set_texture_inspection_model_param (TextureInspectionModel, \ `  
  'gen_result_handle', 'true')`
* Make this short example fast:
`set_texture_inspection_model_param (TextureInspectionModel, \ `  
  'gmm_em_max_iter', 1)`
* Read and add training images
`read_image (TrainImage, 'carpet/carpet_01')`
`add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \ `  
  Indices)`
* Train the model
`train_texture_inspection_model (TextureInspectionModel)`
* Serialize texture inspection model
`serialize_texture_inspection_model (TextureInspectionModel, \ `  
  SerializedItemHandle)`
* Deserialize in Model

---

### get_texture_inspection_model_image

```
get_texture_inspection_model_image ( 
    : ModelImages : TextureInspectionModel : )
```

Get the training images contained in a texture inspection model.

The operator get_texture_inspection_model_image returns all training images contained in a texture inspection model TextureInspectionModel that were added by add_texture_inspection_model_image.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

16.4. TEXTURE INSPECTION

```plaintext
set_texture_inspection_model_param (TextureInspectionModel, \n    'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (ModelImages, TextureInspectionModel, \n    Indices)
* Get added training images
get_texture_inspection_model_image (ModelImagesOut, TextureInspectionModel)
```

**Result**
The operator `get_texture_inspection_model_image` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

**Possible Predecessors**
- `create_texture_inspection_model`
- `set_texture_inspection_model_param`
- `get_texture_inspection_model_param`
- `add_texture_inspection_model_image`

**Possible Successors**
- `train_texture_inspection_model`
- `clear_texture_inspection_model`
- `remove_texture_inspection_model_image`

**Module**

```
get_texture_inspection_model_param ( : : TextureInspectionModel,
    GenParamName : : GenParamValue )
```

**Query parameters of a texture inspection model.**

The operator `get_texture_inspection_model_param` is used to query the values of the different parameters of a texture inspection model (`TextureInspectionModel`). The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. It is possible to query multiple parameters with a single call to `get_texture_inspection_model_param`. All parameters which can be manipulated by `set_texture_inspection_model_param` can be queried. Please refer to the documentation of `set_texture_inspection_model_param` for an explanation of the individual parameters. It is furthermore possible to query the following parameters:

- **'gmm_centers'**: Returns the number of Gaussian distributions which were determined as optimal within the training process. The value can be used as a reference for future texture inspection models. The range of the possible number of distributions is determined by the settings of the parameters 'gmm_pmincenters' and 'gmm_pmaxcenters'. Each image pyramid level can have a different number of Gaussian distributions. By adding an index, the number of Gaussian distributions for specific pyramid levels can be queried. For example, 'gmm_centers_3' returns the number of Gaussian distributions for the third pyramid level.

- **'image_indices'**: Returns the indices of the images that have been added to the texture inspection model using `add_texture_inspection_model_image`. Only indices of images are returned that are currently in the texture inspection model and have not been deleted with `remove_texture_inspection_model_image`.

- **'trained_covartype'**: Returns the type of covariance matrix that was used during training. The user has the possibility to set the preferred type of covariance matrix by setting 'gmm_covartype' with `set_texture_inspection_model_param`. However, if the training with the preferred covariance type fails, training is re-initialized with a less strict 'gmm_covartype'. Hence, if training with 'diag' fails, a further training with 'spherical' is attempted.
In order to avoid confusions regarding the returned tuple length, multivalued parameters, such as 'image_indices', 'gmm_centers', 'levels' and 'novelty_threshold' can only be queried alone i.e. without passing any other parameter to get_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters

\[ \text{TextureInspectionModel} \ \text{(input\_control)} \] \hspace*{1cm} \text{texture\_inspection\_model} \mapsto \text{handle} \\
Handle of the texture inspection model.

\[ \text{GenParamName} \ \text{(input\_control)} \] \hspace*{1cm} \text{string(-array)} \mapsto \text{string} \\
Name of the queried model parameter.

Default value: 'novelty_threshold'

List of values: GenParamName ∈ \{ 'num\_levels', 'levels', 'gen\_result\_handle', 'novelty\_threshold', 'sensitivity', 'patch\_normalization', 'patch\_rotational\_robustness', 'patch\_size', 'gmm\_centers', 'gmm\_sigma', 'gmm\_pmincenters', 'gmm\_pmaxcenters', 'gmm\_preprocessing', 'gmm\_ncomp', 'gmm\_randseed', 'gmm\_em\_max\_iter', 'gmm\_em\_threshold', 'gmm\_em\_regularize', 'gmm\_covartype', 'image\_indices', 'trained\_covartype' \}

\[ \text{GenParamValue} \ \text{(output\_control)} \] \hspace*{1cm} \text{string(-array)} \mapsto \text{integer} / \text{real} / \text{string} \\
Value of the queried model parameter.

Example

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \ 'gmm\_em\_max\_iter', 1)
* Get parameters
get_texture_inspection_model_param (TextureInspectionModel, 'patch\_size', \ PatchSize)
* Read and add training images
read_image (TrainImage, 'carpet/carpet\_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \ Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet\_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \ TextureInspectionModel, \ TextureInspectionResultID)

Result

The operator get_texture_inspection_model_param returns the value 2 (H\_MSG\_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

Possible Predecessors

See also

set_texture_inspection_model_param
Module

Matching

```
get_texture_inspection_result_object (  
    : Object : TextureInspectionResultID,  
    ResultName : )
```

Query iconic results of a texture inspection.

`get_texture_inspection_result_object` queries the iconic result `ResultName` of the handle `TextureInspectionResultID` returned by `apply_texture_inspection_model`. The result handle `TextureInspectionResultID` was only created when `'gen_result_handle'` was set to `'true'` with `set_texture_inspection_model_param`.

For an explanation of the concept of the texture inspection see the introduction of chapter *Inspection / Texture Inspection*.

In the following the possible parameter values for `ResultName` are listed:

'novelty_region': Returns the novelty regions of all pyramid levels in an object tuple. To query the novelty regions of single pyramid levels the corresponding index has to be added, e.g., `'novelty_region_1'`. Please note that if a tuple of images was passed to `apply_texture_inspection_model`, it is only possible to query the novelty regions for the first image within the tuple.

'novelty_score_image': Returns the novelty score images of all pyramid levels in an object tuple. To query the novelty regions of single pyramid levels the corresponding index has to be added, e.g., `'novelty_score_image_1'`. Please note that if a tuple of images was passed to `apply_texture_inspection_model`, it is only possible to query the novelty score images for the first image within the tuple.

--- Parameters ---

- **Object** (output_object) .................................................object(-array) ↼ object
  
  Returned iconic object.

- **TextureInspectionResultID** (input_control) ........................texture_inspection_result ↼ handle
  
  Handle of the texture inspection result.

- **ResultName** (input_control) .........................................string(-array) ↼ string / integer
  
  Name of the iconic object to be returned.

  **Default value:** `'novelty_region'`

  **List of values:** `ResultName ∈ { 'novelty_score_image', 'novelty_region' }`

--- Example ---

* Create texture inspection model
  
  ```
  create_texture_inspection_model ('basic', TextureInspectionModel)
  ```

* Set parameters
  
  ```
  set_texture_inspection_model_param (TextureInspectionModel, \  
    'gen_result_handle', 'true')
  ```

* Make this short example fast:
  
  ```
  set_texture_inspection_model_param (TextureInspectionModel, \  
    'gmm_em_max_iter', 1)
  ```

* Read and add training images
  
  ```
  read_image (TrainImage, 'carpet/carpet_01')
  add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \  
    Indices)
  ```

* Train the model
  
  ```
  train_texture_inspection_model (TextureInspectionModel)
  ```

* Read and apply a test image
  
  ```
  read_image (TestImage, 'carpet/carpet_02')
  apply_texture_inspection_model (TestImage, DefectCandidates, \  
    TextureInspectionModel, \  
    TextureInspectionResultID)
  ```
Get result objects

get_texture_inspection_result_object (Object, TextureInspectionResultID, \n'novelty_score_image')

--- Result

The operator get_texture_inspection_result_object returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

--- Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Possible Predecessors

apply_texture_inspection_model

--- Possible Successors

clear_texture_inspection_result, clear_texture_inspection_model

--- Module

**read_texture_inspection_model** (  
: : FileName : TextureInspectionModel )

Read a texture inspection model from a file.

read_texture_inspection_model reads a texture inspection model that has been stored with write_texture_inspection_model. Since the training of a texture inspection model can consume a relatively long time, the texture inspection model is typically trained in an offline process and written to a file with write_texture_inspection_model. In the online process the texture inspection model is read with read_texture_inspection_model and subsequently used for evaluation with apply_texture_inspection_model. The default HALCON file extension for the texture inspection model is ‘htim’.

After reading a trained texture inspection model, it is possible to classify test images using apply_texture_inspection_model. However, retraining this model can only be done, if the read model has images. Furthermore, modifying parameters of the model leads to an entire retraining.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

--- Parameters

- **FileName** (input_control) .......................... filename.read  ~ string
  File name.
  File extension: .htim
- **TextureInspectionModel** (output_control) .................... texture_inspection_model  ~ handle
  Handle of the texture inspection model.

--- Example

* Create texture inspection model
  create_texture_inspection_model ('basic', TextureInspectionModel)

  * Make this short example fast:
    set_texture_inspection_model_param (TextureInspectionModel, \n      'gmm_em_max_iter', 1)

  * Read and add training images
    read_image (TrainImage, 'carpet/carpet_01')
    add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \n      'carpet_01')
16.4. TEXTURE INSPECTION

Indices)

* Train the model
  train_texture_inspection_model (TextureInspectionModel)
* Write out texture inspection model
  write_texture_inspection_model (TextureInspectionModel, \n   'ExampleModel.htim')
* Read in Model
  read_texture_inspection_model ('ExampleModel.htim', \n   TextureInspectionModelRead)
* Read and apply a test image
  read_image (TestImage, 'carpet/carpet_02')
  apply_texture_inspection_model (TestImage, DefectCandidates, \n   TextureInspectionModelRead, \n   TextureInspectionResultID)

If the parameters are valid, the operator read_texture_inspection_model returns the value 2
(H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific
operators even though the handle is used as an input parameter by those operators.

remove_texture_inspection_model_image (\n   : : TextureInspectionModel, Indices : RemainingIndices )

Clear all or a user-defined subset of the images of a texture inspection model.

remove_texture_inspection_model_image clears all or certain selected images that have been stored
in a texture inspection model TextureInspectionModel.

On the one hand, the usage of remove_texture_inspection_model_image is recommended to reduce
the storage space of a saved texture inspection model. This is especially of advantage if the texture inspection
model has been trained in an offline process and written with write_texture_inspection_model. In
this case, test images can still be classified using apply_texture_inspection_model, while the required
storage space is reduced to a minimum. On the other hand, it offers a simple way to delete certain selected images
of the texture inspection model that are not needed (anymore) for a subsequent classification process. This allows
the user to proceed with an entirely configured model, while only the used image data has to be tuned to solve the
underlying inspection problem. Please note that after removing images from the model a retraining is required.

In order to specifically delete images from the texture inspection model, the indices of the respective images have
to be specified in the parameter Indices. A validation of all images that are still in the texture inspection model
can be made using the value 'image_indices' in get_texture_inspection_model_param. If the user
still passes unassigned indices to delete images, these indices are ignored. Besides the above mentioned option, `remove_texture_inspection_model_image` also allows to set the parameter `Indices` to the value 'all'. In this case, all images of the texture inspection model are deleted.

It should be noted that after deleting all images, the model can only be (re)trained, if new images are added using `add_texture_inspection_model_image`. In the case that only a subset of all images has been deleted, a call of `train_texture_inspection_model` requires all steps of the training to be executed, since potentially still available training data does not match the used data.

After calling `remove_texture_inspection_model_image`, the remaining indices of the images that are still in the texture inspection model are returned in the parameter `RemainingIndices`.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>TextureInspectionModel</code></td>

set_texture_inspection_model_param ( : : TextureInspectionModel,

GenParamName, GenParamValue : )

Set parameters of a texture inspection model.

The operator set_texture_inspection_model_param is used to manipulate the parameters of a texture inspection model TextureInspectionModel. The current parameter settings can be queried with the operator get_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

General parameters:

*num_levels*: Determines the number of pyramid levels used within the texture inspection process. The number of pyramid levels affects the inspection results as well as the runtime of train_texture_inspection_model and apply_texture_inspection_model. Per default the number of levels is estimated by the size of the training images. It should be noted, that no more than 5 pyramid levels are used by the estimation process.

Changing this parameter can require a complete new training of the texture inspection model. No retraining is required if the number of levels of a trained texture inspection model are merely reduced.

If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then you can save a lot of runtime by setting the levels of interest explicitly with *levels*.

Values: integer values larger or equal to 1 or *auto*

Default: *auto*

*levels*: Determines the pyramid levels used within the texture inspection process. The number of pyramid levels affects the inspection results as well as the runtime of train_texture_inspection_model and apply_texture_inspection_model. Per default the pyramid levels are determined by the value of *num_levels*. If for example *num_levels* is set to four, then the texture inspection is performed for levels 1 to 4. If all available levels should be trained, the value has to be set to *auto*.

Changing this parameter can require a complete new training of the texture inspection model. No retraining is required if the number of levels of a trained texture inspection model are merely reduced.

If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then you can save a lot of runtime by excluding unwanted levels by setting the pyramid levels *levels* explicitly.

In order to avoid confusions regarding the returned tuple length, *levels* can only be set alone i.e. without passing any other parameter to set_texture_inspection_model_param.

Values: a monotonically increasing tuple of integer values larger or equal to 1, or *auto*

Default: *auto*

*gen_result_handle*: This parameter determines whether or not a result handle is returned by apply_texture_inspection_model. If set to *true*, the individual pyramid level results can be queried from the texture result handle with get_texture_inspection_result_object. This is useful for debugging and fine tuning.

If set to *false*, apply_texture_inspection_model only returns a novelty region.

Values: *true*, *false*

Default: *false*

Parameters which influence the automatic novelty threshold calculation:
'novelty_threshold': This parameter sets the values of the novelty thresholds, which distinguish between defective and non-defective texture. The novelty thresholds are passed as a tuple and are set for all pyramid levels at once. Therefore, the number of elements must be equal to the number of pyramid levels 'num_levels'.

Setting the novelty thresholds prior to training has no effect since the training automatically determines novelty thresholds. Hence the novelty thresholds should be adapted after the training. A typical use case is the fine tuning to optimize the results of apply_texture_inspection_model. Please note, if the novelty thresholds have been set explicitly, a new call of train_texture_inspection_model will re-estimate the novelty thresholds automatically and overwrite any explicitly set novelty thresholds.

It is possible to add an index to set the novelty threshold of a specific pyramid level. For example, 'novelty_threshold_3' sets the novelty threshold for the third pyramid level.

Values: integer or float values larger or equal to 0 and smaller or equal to 710
Default: Is determined by train_texture_inspection_model

'sensitivity': This parameter influences the sensitivity of the novelty thresholds which are determined during the training with train_texture_inspection_model. Per default 'sensitivity' is set to 0.0, which means the novelty thresholds from the training are used directly when calling apply_texture_inspection_model. If a negative value for the parameter 'sensitivity' is used, the value is added to the novelty boundaries. Hence, a sensitivity value below 0.0 increments the novelty thresholds and therefore leads to potentially fewer detected errors. If instead a positive value is set, the novelty thresholds are decremented which leads to potentially more detected errors.

The automatically determined novelty thresholds can be changed after the training with the parameter 'novelty_threshold'.

Values: float or integer value
Default: 0.0

Parameters that influence the texture features:

'patch_normalization': Determines the method used to normalize the texture features. A normalization is required if the lighting between different images is not consistent. If set to 'weber', the patches are normalized in accordance with the Weber-Fechner law. If the parameter is set to 'none', no feature normalization is performed.

Changing this parameter requires a complete new training of the texture inspection model.

Values: 'none', 'weber'
Default: 'none'

'patch_rotational_robustness': If set to 'true', the texture features are sorted in a way to obtain a certain amount of rotational invariance. Sorting the features leads to a loss of feature information and generally makes the texture inspection less sensitive. Also, the runtime is slightly increased. If the parameter is set to 'false', the texture features are not sorted.

Alternatively, it is possible to capture all possible rotations within the training images. Increasing the training images leads to an increase of the training time.

Changing this parameter requires a complete new training of the texture inspection model.

Values: 'true', 'false'
Default: 'false'

'patch_size': This parameter determines the diameter of the extracted texture feature patches in pixels. Higher patch sizes increase the runtime significantly. Therefore this parameter should only be changed with great care. First try to change the image resolution or the number of pyramids used.

Changing this parameter requires a complete new training of the texture inspection model.

Values: odd integer values between 1 and 11
Default: 5

Advanced parameters that influence the GMM classifiers:

Internally, the texture inspection model uses a Gaussian Mixture Model (GMM) classifier. In general, it is recommended not to change the GMM parameters, but for experienced users this is still possible.

Changing these parameters requires a new training of the texture inspection model.

In the following, the parameters which influence the GMM classifiers are described. For more information on classification with GMM classifiers, see create_class_gmm and train_class_gmm.
'gmm_sigma': This parameter determines the standard deviation of the Gaussian noise which is added to the training samples (see add_sample_class_gmm).
Values: integer or float values larger or equal to 0.0
Default: 0.0

'gmm_pmincenters': This parameter determines the minimum number of Gaussian distributions per class. 'gmm_pmincenters' cannot be set to a value larger than the current value of 'gmm_pmaxcenters'.
Values: integer value larger or equal to 1 and less or equal to 'gmm_pmaxcenters'
Default: 12

'gmm_pmaxcenters': This parameter determines the maximum number of Gaussian distributions per class. 'gmm_pmaxcenters' cannot be set to a value smaller than the current value of 'gmm_pmincenters'.
Values: integer value larger or equal to 'gmm_pmincenters'
Default: 12

'gmm_preprocessing': This parameter determines the type of preprocessing used to transform the feature vectors.
Values: 'principal_components', 'normalization', 'none'
Default: 'normalization'

'gmm_ncomp': This parameter manipulates the preprocessing in case 'principal_components' is chosen as the preprocessing method. More specifically, it determines the dimension of the transformed feature vectors. It needs to be chosen such that it is smaller than the feature dimension, which is 'patch_size' × 'patch_size'. If the 'patch_size' is changed such that 'patch_size' × 'patch_size' < 'gmm_ncomp', the parameter is manipulated accordingly.
Values: integer value larger or equal to 1
Default: 15

'gmm_randseed': This parameter determines the initialization value for the random number generator, which is required to initialize the GMM with random values.
Values: integer value
Default: 42

'gmm_em_max_iter': This parameter determines the maximum number of iterations of the expectation maximization algorithm.
Values: integer values larger or equal to 0
Default: 100

'gmm_em_threshold': This parameter determines the threshold for the relative change of the error for the expectation maximization algorithm to terminate.
Values: integer or float value larger or equal to 0 and smaller than 1.0
Default: 0.001

'gmm_em_regularize': This parameter determines the regularization value for preventing covariance matrix singularity within the training process.
Values: integer or float values larger or equal to 0 and smaller than 1.0
Default: 0.0001

'gmm_covartype': This parameter determines the type of covariance matrix that is used internally.
Values: 'spherical', 'diag', 'full'
Default: 'diag'

Changing the parameters of a trained texture inspection model
If parameters of a texture inspection model are manipulated after a successful call of train_texture_inspection_model, the texture inspection model usually needs to be retrained. Depending on which parameters are changed, different parts of the training need to be recalculated.
A manipulation of the parameters 'gmm_*' requires a new training of the classifiers. Since a new classifier yields different novelty scores, the novelty thresholds also need to be recalculated. The parameter 'patch_*' requires a complete new training of the texture inspection model. The parameters 'num_levels' and 'levels' require a retraining if the number of levels is increased or levels are set which were not trained beforehand. For example, setting 'levels' from [1,2,3] to [1,3] does not require a retraining. The operator 'gen_result_handle' has no effect on a trained texture inspection model and can be manipulated without requiring any retraining.
16.4. TEXTURE INSPECTION

Parameters

- **TextureInspectionModel** (input_control) ........................ texture_inspection_model \(\rightarrow\) handle
  Handle of the texture inspection model.

- **GenParamName** (input_control) ........................ attribute.name(-array) \(\rightarrow\) string
  Name of the model parameter to be adjusted.
  **Default value:** 'gen_result_handle'
  **List of values:** `GenParamName \(\in\) {'num_levels', 'levels', 'gen_result_handle', 'novelty_threshold', 'sensitivity', 'patch_normalization', 'patch_rotational_robustness', 'patch_size', 'gmm_sigma', 'gmm_pmincenters', 'gmm_pmaxcenters', 'gmm_preprocessing', 'gmm_ncomp', 'gmm_randseed', 'gmm_em_max_iter', 'gmm_em_threshold', 'gmm_em_regularize', 'gmm_covartype'}`

- **GenParamValue** (input_control) ........................ attribute.value(-array) \(\rightarrow\) integer / real / string
  New value of the model parameter.
  **Default value:** 'true'
  **List of values:** `GenParamValue \(\in\) {5, 'auto', 'true', 'false', 'none', 'weber', 'principal_components', 'normalization'}`

Example

* Create texture inspection model
  `create_texture_inspection_model ('basic', TextureInspectionModel)`
* Set parameters
  `set_texture_inspection_model_param (TextureInspectionModel, \`
  'gen_result_handle', 'true')`
* Make this short example fast:
  `set_texture_inspection_model_param (TextureInspectionModel, \`
  'gmm_em_max_iter', 1)`
* Read and add training images
  `read_image (TrainImage, 'carpet/carpet_01')`
  `add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \`
  Indices)`
* Train the model
  `train_texture_inspection_model (TextureInspectionModel)`
* Read and apply a test image
  `read_image (TestImage, 'carpet/carpet_02')`
  `apply_texture_inspection_model (TestImage, DefectCandidates, \`
  TextureInspectionModel, \`
  TextureInspectionResultID)`

Result

The operator `set_texture_inspection_model_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **TextureInspectionModel**

  During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- **create_texture_inspection_model**

Possible Successors

- **add_texture_inspection_model_image**
  **train_texture_inspection_model**
CHAPTER 16 INSPECTION

Matching

train_texture_inspection_model ( : : TextureInspectionModel : )

Train a texture inspection model.

train_texture_inspection_model trains a texture inspection model with all training images which were added by add_texture_inspection_model_image.

The complete texture inspection process works with image pyramids. The depth of the pyramid is determined by the parameter 'num_levels' (or 'levels' if the levels have been set explicitly). In the first step of the training, texture features are extracted and added to the set of training samples for each pyramid level. For each pyramid level a Gaussian Mixture Model (GMM) classifier is determined with all training samples of the corresponding pyramid level. In a third step, the training samples are used to determine a novelty threshold for each pyramid level. In the following, the three training steps are explained in detail:

1. **Feature extraction** extracts a feature for each pixel within the training images. The texture features are calculated according to the settings of the 'patch_*' parameters, which can be manipulated with set_texture_inspection_model_param. Each texture feature is added to the training data of the GMM.

2. **During the training** of the GMMs, the optimal 'gmm_*' parameters are calculated from the training data. The dimension of the single GMMs is determined by the size of the feature patches. Please refer to set_texture_inspection_model_param for details. For large patch sizes, it can be extremely difficult to obtain a good approximation of the optimal GMM parameters. Also, the run time and memory usage rises significantly. Therefore we recommend to alter the default patch size with care.

   More information on GMM classifiers can be found in the description of the operator create_class_gmm.

3. **The calculation of the novelty thresholds** is required to be able to distinguish between defective and non-defective texture. First, the novelty score of each training sample is determined with the GMMs determined in step 2. Then, based on the resulting novelty scores, novelty thresholds are determined for each pyramid level. The automatic determination of the novelty thresholds can be influenced with the parameter 'sensitivity' that can be set with set_texture_inspection_model_param.

After the training was successful it is possible to classify images with apply_texture_inspection_model. Each pixel is assigned a 'novelty score' that is compared to the novelty threshold, which was determined within the third step of the training. For optimal results it is possible to adapt the novelty threshold of the single pyramid levels with set_texture_inspection_model_param.

In general, the manipulation of all parameters, with the exception of 'gen_result_handle' and 'sensitivity', requires a retraining of the texture inspection model. Depending on which part of the training is affected by the corresponding parameter, either the whole training or only single steps have to be recalculated. This can lead to strong variations in the time required for retraining a texture inspection model. A precise description which parameters influence which parts of the algorithm are illustrated in set_texture_inspection_model_param.

For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters

<table>
<thead>
<tr>
<th>TextureInspectionModel (input_control)</th>
<th>texture_inspection_model</th>
<th>handle</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handle of the texture inspection model.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)  
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
    'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
    Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
    TextureInspectionModel, \
    TextureInspectionResultID)

Result

The operator `train_texture_inspection_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- add_texture_inspection_model_image, set_texture_inspection_model_param

Possible Successors

- apply_texture_inspection_model, clear_texture_inspection_model,
- remove_texture_inspection_model_image, write_texture_inspection_model,
- serialize_texture_inspection_model

Module

Matching

write_texture_inspection_model ( : : TextureInspectionModel, 
    FileName : )

Write a texture inspection model to a file.

`write_texture_inspection_model` writes the texture inspection model `TextureInspectionModel` to the file given by `FileName`. The default HALCON file extension for the texture inspection model is 'htim'. `write_texture_inspection_model` is typically called after the texture inspection model has been trained with `train_texture_inspection_model`. However, it can also be used to save an untrained model. The texture inspection model can be read with `read_texture_inspection_model`. It should be noted that `write_texture_inspection_model` does not write any training samples that possibly have been stored in the texture inspection model. Instead, only the currently set parameters of the model, possibly added images and, if trained, the classifiers of the single pyramid levels are written.
For an explanation of the concept of the texture inspection see the introduction of chapter Inspection / Texture Inspection.

Parameters

> **TextureInspectionModel** (input_control) texture_inspection_model ~ handle
> Handle of the texture inspection model.

> **FileName** (input_control) filename.write ~ string
> File name.

  * File extension: .htim

Example

* Create texture inspection model
  create_texture_inspection_model ('basic', TextureInspectionModel)

* Make this short example fast:
  set_texture_inspection_model_param (TextureInspectionModel, 'gmm_em_max_iter', 1)

* Read and add training images
  read_image (TrainImage, 'carpet/carpet_01')
  add_texture_inspection_model_image (TrainImage, TextureInspectionModel, Indices)

* Train the model
  train_texture_inspection_model (TextureInspectionModel)

* Write out texture inspection model
  write_texture_inspection_model (TextureInspectionModel, 'ExampleModel.htim')

Result

If the parameters are valid, the operator write_texture_inspection_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

16.5 Variation Model

clear_train_data_variation_model ( : : ModelID : )

Free the memory of the training data of a variation model.

clear_train_data_variation_model frees the memory of a variation model that was created by create_variation_model. clear_train_data_variation_model can be used to reduce the amount of memory required for the variation model (in main memory as well as when writing the model to
16.5. VARIATION MODEL

file with write_variation_model. clear_train_data_variation_model can only be called if the model has been prepared for comparison with an image with prepare_variation_model. After the call to clear_train_data_variation_model the variation model can only be used for image comparison with compare_variation_model or compare_ext_variation_model. The model cannot be trained any further. Furthermore, the images used for the image comparison can no longer be read with get_variation_model. If they are required, get_variation_model must be called before clear_train_data_variation_model is called.

Parameters

 ModelID (input_control) variation_model ~ handle ID of the variation model.

Result
clear_train_data_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

Multithreading type: reentrant (runs in parallel with non-exclusive operators).
Multithreading scope: global (may be called from any thread).
Processed without parallelization.

This operator modifies the state of the following input parameter:

• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

\begin{verbatim}
\textbf{compare_ext_variation_model} ( Image : Region : ModelID, Mode : )
\end{verbatim}

\textit{Compare an image to a variation model.}

\texttt{compare_ext\_variation\_model} compares the input image \texttt{Image} to the variation model given by \texttt{ModelID}. \texttt{compare_ext\_variation\_model} is an extension of \texttt{compare\_variation\_model} that provides more modes for the image comparison. Before \texttt{compare_ext\_variation\_model} can be called, the two internal threshold images of the variation model must have been created with \texttt{prepare\_variation\_model} or \texttt{prepare\_direct\_variation\_model}. Let \( c(x,y) \) denote the input image \texttt{Image} and \( t_u, t_l \) denote the two threshold images (see \texttt{prepare\_variation\_model} or \texttt{prepare\_direct\_variation\_model}). Then, for \texttt{Mode = 'absolute'} the output region \texttt{Region} contains all points that differ substantially from the model, i.e., the points that fulfill the following condition:

\[ c(x,y) > t_u(x,y) \lor c(x,y) < t_l(x,y) . \]

This mode is identical to \texttt{compare\_variation\_model}. For \texttt{Mode = 'light'}, \texttt{Region} contains all points that are too bright:

\[ c(x,y) > t_u(x,y) . \]

For \texttt{Mode = 'dark'}, \texttt{Region} contains all points that are too dark:

\[ c(x,y) < t_l(x,y) . \]

Finally, for \texttt{Mode = 'light\_dark'} two regions are returned in \texttt{Region}. The first region contains the result of \texttt{Mode = 'light'}, while the second region contains the result of \texttt{Mode = 'dark'}. The respective regions can be selected with \texttt{select\_obj}.

\begin{verbatim}
Parameters
\end{verbatim}

\begin{itemize}
\item \textbf{Image} (input\_object) \hspace{1em} \texttt{singlechannelimage(-array)} \hspace{1em} \texttt{object : byte / int2 / uint2} \hspace{1em} Image of the object to be compared.
\item \textbf{Region} (output\_object) \hspace{1em} \texttt{region(-array)} \hspace{1em} \texttt{object} \hspace{1em} Region containing the points that differ substantially from the model.
\item \textbf{ModelID} (input\_control) \hspace{1em} \texttt{variation\_model} \hspace{1em} \texttt{handle} \hspace{1em} ID of the variation model.
\item \textbf{Mode} (input\_control) \hspace{1em} \texttt{string} \hspace{1em} \texttt{string} \hspace{1em} Method used for comparing the variation model.
\end{itemize}

compare_variation_model ( Image : Region : ModelID : )

Compare an image to a variation model.

compare_variation_model compares the input image Image to the variation model given
by ModelID. Before compare_variation_model can be called, the two internal threshold
images of the variation model must have been created with prepare_variation_model or
prepare_direct_variation_model. Let \( c(x,y) \) denote the input image Image and \( t_u,l \) denote the two
threshold images (see prepare_variation_model or prepare_direct_variation_model). Then
the output region Region contains all points that differ substantially from the model, i.e., the points that fulfill the
following condition:

\[
  c(x,y) > t_u(x,y) \lor c(x,y) < t_l(x,y)
\]

If only too bright or too dark errors should be segmented the operator compare_ext_variation_model can
be used.
Parameters

- **Image** (input_object) ........................................................ singlechannelimage(-array) $\rightsquigarrow$ object : byte / int2 / uint2
  Image of the object to be compared.
- **Region** (output_object) ........................................................ region(-array) $\rightsquigarrow$ object
  Region containing the points that differ substantially from the model.
- **ModelID** (input_control) .................................................... variation_model $\rightsquigarrow$ handle
  ID of the variation model.

Example

```c
open_framegrabber ('File', 1, 1, 0, 0, 0, 0, 'default', -1, 
                 'default', -1, 'default', 'testimages.seq', 'default', 
                 -1, -1, AcqHandle)
read_region (Region, 'model.reg')
area_center (Region, Area, RowRef, ColumnRef)
read_shape_model ('model.shm', TemplateID)
read_variation_model ('model.var', ModelID)
for K := 1 to 10000 by 1
  grab_image (Image, AcqHandle)
  find_shape_model (Image, TemplateID, 0, rad(360), 0.5, 1, 0.5, 
                    'true', 4, 0.9, Row, Column, Angle, Score)
  dev_display (Image)
  if (|Score| == 1)
    vector_angle_to_rigid (Row, Column, Angle, RowRef, 
                          ColumnRef, 0, HomMat2D)
    affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', 
                        'false')
    compare_variation_model (ImageTrans, RegionDiff, ModelID)
    dev_display (RegionDiff)
  endif
endfor
close_framegrabber (AcqHandle)
```

Result

`compare_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct and if the internal threshold images have been generated with `prepare_variation_model` or `prepare_direct_variation_model`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

Module

Matching
Create a variation model for image comparison.

`create_variation_model` creates a variation model that can be used for image comparison. The handle for the variation model is returned in `ModelID`.

Typically, the variation model is used to discriminate correctly manufactured objects ("good objects") from incorrectly manufactured objects ("bad objects"). It is assumed that the discrimination can be done solely based on the gray values of the object.

The variation model consists of an ideal image of the object to which the images of the objects to be tested are compared later on with `compare_variation_model` or `compare_ext_variation_model`, and an image that represents the amount of gray value variation at every point of the object. The size of the images with which the object model is trained and with which the model is compared later on is passed in `Width` and `Height`, respectively. The image type of the images used for training and comparison is passed in `Type`.

The variation model is trained using multiple images of good objects. Therefore, it is essential that the training images show the objects in the same position and rotation. If this cannot be guaranteed by external means, the pose of the object can, for example, be determined by using matching (see `find_shape_model`). The image can then be transformed to a reference pose with `affine_trans_image`.

The parameter `Mode` is used to determine how the image of the ideal object and the corresponding variation image are computed. For `Mode='standard'`, the ideal image of the object is computed as the mean of all training images at the respective image positions. The corresponding variation image is computed as the standard deviation of the training images at the respective image positions. This mode has the advantage that the variation model can be trained iteratively, i.e., as soon as an image of a good object becomes available, it can be trained with `train_variation_model`. The disadvantage of this mode is that great care must be taken to ensure that only images of good objects are trained, because the mean and standard deviation are not robust against outliers, i.e., if an image of a bad object is trained inadvertently, the accuracy of the ideal object image and that of the variation image might be degraded.

If it cannot be avoided that the variation model is trained with some images of objects that can contain errors, `Mode` can be set to `'robust'`. In this mode, the image of the ideal object is computed as the median of all training images at the respective image positions. The corresponding variation image is computed as a suitably scaled median absolute deviation of the training images and the median image at the respective image positions. This mode has the advantage that it is robust against outliers. It has the disadvantage that it cannot be trained iteratively, i.e., all training images must be accumulated using `concat_obj` and be trained with `train_variation_model` in a single call.

In some cases, it is impossible to acquire multiple training images. In this case, a useful variation image cannot be trained from the single training image. To solve this problem, variations of the training image can be created synthetically, e.g., by shifting the training image by ±1 pixel in the row and column directions or by using gray value morphology (e.g., `gray_erosion_shape` and `gray_dilation_shape`), and then training the synthetically modified images. A different possibility to create the variation model from a single image is to create the model with `Mode='direct'`. In this case, the variation model can only be trained by specifying the ideal image and the variation image directly with `prepare_direct_variation_model`. Since the variation typically is large at the edges of the object, edge operators like `sobel_amp`, `edges_image`, or `gray_range_rect` should be used to create the variation image.

</tbody>
</table>
**Mode** (input_control)  .................................................. string  ⇒ string
Method used for computing the variation model.
**Default value:** 'standard'
**Suggested values:** Mode ∈ {'standard', 'robust', 'direct'}

**ModelID** (output_control)  .................................................. variation_model  ⇒ handle
ID of the variation model.

---

**Complexity**
A variation model created with `create_variation_model` requires $12 \times \text{Width} \times \text{Height}$ bytes of memory for Mode = 'standard' and Mode = 'robust' for Type = 'byte'. For Type = 'uint2' and Type = 'int2', $14 \times \text{Width} \times \text{Height}$ are required. For Mode = 'direct' and after the training data has been cleared with `clear_train_data_variation_model`, $2 \times \text{Width} \times \text{Height}$ bytes are required for Type = 'byte' and $4 \times \text{Width} \times \text{Height}$ for the other image types.

---

**Result**
`create_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

---

**Execution Information**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

---

**Possible Successors**
train_variation_model, prepare_direct_variation_model

Module

Matching

get_thresh_images_variation_model ( : MinImage, MaxImage : ModelID : )

Return the threshold images used for image comparison by a variation model.

get_thresh_images_variation_model returns the threshold images of the variation model ModelID in MaxImage and MinImage. The threshold images must be computed with prepare_variation_model or prepare_direct_variation_model before they can be read out. The formula used for calculating the threshold images is described with prepare_variation_model or prepare_direct_variation_model. The threshold images are used in compare_variation_model and compare_ext_variation_model to detect too large deviations of an image with respect to the model. As described with compare_variation_model and compare_ext_variation_model, gray values outside the interval given by MinImage and MaxImage are regarded as errors.

Parameters
- MinImage (output_object) image : object : byte / int2 / uint2
  Threshold image for the lower threshold.
- MaxImage (output_object) image : object : real
  Threshold image for the upper threshold.
- ModelID (input_control) variation_model : handle
  ID of the variation model.

Result
get_thresh_images_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
- prepare_variation_model, prepare_direct_variation_model

See also
- compare_variation_model, compare_ext_variation_model

Module

Matching

get Variation_model ( : Image, VarImage : ModelID : )

Return the images used for image comparison by a variation model.

get_variation_model returns the image of the ideal object and the corresponding variation image of the variation model ModelID in Image and VarImage, respectively. The returned images can be used to check whether an image of a bad object has been trained with train_variation_model. This can be seen from the variation image. If an image of a bad object has been trained, the variation image typically has large variations in areas that should exhibit no variations.
Parameters

- **Image** (output_object) ................................. image  \( \sim object \) : byte / int2 / uint2
  Image of the trained object.
- **VarImage** (output_object) .............................. image  \( \sim object \) : real
  Variation image of the trained object.
- **ModelID** (input_control) .............................. variation_model  \( \sim handle \)
  ID of the variation model.

Result

get_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

prepare_variation_model, compare_variation_model, compare_ext_variation_model

Module

Matching

**prepare_direct_variation_model** ( RefImage, VarImage : : ModelID, AbsThreshold, VarThreshold : )

Prepare a variation model for comparison with an image.

**prepare_direct_variation_model** prepares a variation model for the image comparison with `compare_variation_model` or `compare_ext_variation_model`. The variation model must have been created with `Mode='direct'` with `create_variation_model`. In contrast to `prepare_variation_model`, the ideal image of the object and the corresponding variation image are not computed with `train_variation_model`, but are specified directly in `RefImage` and `VarImage`. This is useful if the variation model should be created from a single image, as described with `create_variation_model`. The variation image should typically be created with edge operators like `sobel_amp`, `edges_image`, or `gray_range_rect`.

**prepare_direct_variation_model** converts the ideal image `RefImage` and the variation image `VarImage` into two threshold images and stores them in the variation model. These threshold images are used in `compare_variation_model` or `compare_ext_variation_model` to perform the comparison of the current image to the variation model.

Two thresholds are used to compute the threshold images. The parameter `AbsThreshold` determines the minimum amount of gray levels by which the image of the current object must differ from the image of the ideal object. The parameter `VarThreshold` determines a factor relative to the variation image for the minimum difference of the current image and the ideal image. `VarThreshold` utilizes `VarImage` to define regions, in which differences in gray values may occur which should not be counted as errors. This allows variations for specific parts of the object to inspect. `AbsThreshold` and `VarThreshold` each can contain one or two values. If two values are specified, different thresholds can be determined for too bright and too dark pixels. In this mode, the first value refers to too bright pixels, while the second value refers to too dark pixels. If one value is specified, this value refers to both the too bright and too dark pixels. Let \( i(x,y) \) be the ideal image `RefImage`, \( v(x,y) \) the variation image `VarImage`, \( a_u = \text{AbsThreshold}_0 \), \( a_l = \text{AbsThreshold}_1 \), \( b_u = \text{VarThreshold}_0 \), and \( b_l = \text{VarThreshold}_1 \) (or \( a_u = \text{AbsThreshold} \), \( a_l = \text{AbsThreshold} \), \( b_u = \text{VarThreshold} \), and \( b_l = \text{VarThreshold} \), respectively). Then the two threshold images \( t_{u,l} \) are computed as follows:

\[
  t_u(x,y) = i(x,y) + \max\{a_u, b_u v(x,y)\} \quad t_l(x,y) = i(x,y) - \max\{a_l, b_l v(x,y)\}.
\]
If the current image \( c(x, y) \) is compared to the variation model using `compare_variation_model`, the output region contains all points that differ substantially from the model, i.e., that fulfill the following condition:

\[
c(x, y) > t_u(x, y) \lor c(x, y) < t_l(x, y)
\]

In `compare_ext_variation_model`, extended comparison modes are available, which return only too bright errors, only too dark errors, or bright and dark errors as separate regions.

After the threshold images have been created they can be read out with `get_thresh_images_variation_model`.

It should be noted that `RefImage` and `VarImage` are not stored as the ideal and variation images in the model to save memory in the model.

---

### Parameters

- **RefImage** (input_object) \( \sim \) singlechannelimage \( \sim \) object: byte / int2 / uint2
  - Reference image of the object.

- **VarImage** (input_object) \( \sim \) singlechannelimage \( \sim \) object: byte / int2 / uint2
  - Variation image of the object.

- **ModelID** (input_control) \( \sim \) variation_model \( \sim \) handle
  - ID of the variation model.

- **AbsThreshold** (input_control) \( \sim \) number(-array) \( \sim \) real / integer
  - Absolute minimum threshold for the differences between the image and the variation model.
  - **Default value:** 10
  - **Suggested values:** \( \text{AbsThreshold} \in \{0, 5, 10, 15, 20, 30, 40, 50\} \)
  - **Restriction:** \( \text{AbsThreshold} \geq 0 \)

- **VarThreshold** (input_control) \( \sim \) number(-array) \( \sim \) real / integer
  - Threshold for the differences based on the variation of the variation model.
  - **Default value:** 2
  - **Suggested values:** \( \text{VarThreshold} \in \{1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5\} \)
  - **Restriction:** \( \text{VarThreshold} \geq 0 \)

---

### Example

```halcon
read_image (Image, 'model')
sobel_amp (Image, VarImage, 'sum_abs', 3)
get_image_pointer1 (Image, Pointer, Type, Width, Height)
create_variation_model (Width, Height, Type, 'direct', ModelID)
prepare_direct_variation_model (Image, VarImage, ModelID, 20, 1)
write_variation_model (ModelID, 'model.var')
```

**Result**

`prepare_direct_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

### Possible Predecessors

- `sobel_amp, edges_image, gray_range_rect`

### Possible Successors

- `compare_variation_model, compare_ext_variation_model, get_thresh_images_variation_model, write_variation_model`
prepare_variation_model

Prepare a variation model for comparison with an image.

prepare_variation_model prepares a variation model for the image comparison with compare_variation_model or compare_ext_variation_model. This is done by converting the ideal image and the variation image that have been trained with train_variation_model into two threshold images and storing them in the variation model. These threshold images are used in compare_variation_model or compare_ext_variation_model to speed up the comparison of the current image to the variation model.

Two thresholds are used to compute the threshold images. The parameter AbsThreshold determines the minimum amount of gray levels by which the image of the current object must differ from the image of the ideal object. The parameter VarThreshold determines a factor relative to the variation image for the minimum difference of the current image and the ideal image. AbsThreshold and VarThreshold each can contain one or two values. If two values are specified, different thresholds can be determined for too bright and too dark pixels. In this mode, the first value refers to too bright pixels, while the second value refers to too dark pixels. If one value is specified, this value refers to both the too bright and too dark pixels. Let \( i(x, y) \) be the ideal image, \( v(x, y) \) the variation image, \( a_u = \text{AbsThreshold}[0], a_l = \text{AbsThreshold}[1], b_u = \text{VarThreshold}[0], \) and \( b_l = \text{VarThreshold}[1] \) (or \( a_u = \text{AbsThreshold}, a_l = \text{AbsThreshold}, b_u = \text{VarThreshold}, \) and \( b_l = \text{VarThreshold}, \) respectively). Then the two threshold images \( t_u, t_l \) are computed as follows:

\[
    t_u(x, y) = i(x, y) + \max\{a_u, b_u, v(x, y)\} \\
    t_l(x, y) = i(x, y) - \max\{a_l, b_l, v(x, y)\}
\]

If the current image \( c(x, y) \) is compared to the variation model using compare_variation_model, the output region contains all points that differ substantially from the model, i.e., that fulfill the following condition:

\[
    c(x, y) > t_u(x, y) \lor c(x, y) < t_l(x, y)
\]

In compare_ext_variation_model, extended comparison modes are available, which return only too bright errors, only too dark errors, or bright and dark errors as separate regions.

After the threshold images have been created they can be read out with get_thresh_images_variation_model. Furthermore, the training data can be deleted with clear_train_data_variation_model to save memory.

### Parameters

- **ModelID** (input_control) variation_model --> handle ID of the variation model.
- **AbsThreshold** (input_control) number(-array) real/integer Absolute minimum threshold for the differences between the image and the variation model.
  
  **Default value:** 10
  **Suggested values:** AbsThreshold \( \in \{0, 5, 10, 15, 20, 30, 40, 50\} \)
  **Restriction:** AbsThreshold >= 0
- **VarThreshold** (input_control) number(-array) real/integer Threshold for the differences based on the variation of the variation model.
  
  **Default value:** 2
  **Suggested values:** VarThreshold \( \in \{1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5\} \)
  **Restriction:** VarThreshold >= 0

### Result

prepare_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

### Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

serialize_variation_model ( : : ModelID : SerializedItemHandle )

Serialize a variation model.

serialize_variation_model serializes the data of a variation model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_variation_model is converted to a serialized item. The variation model is defined by the handle ModelID. The serialized variation model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_variation_model.

Parameters

▷ ModelID (input_control) .............................................. variation_model ↦ handle
  ID of the variation model.
▷ SerializedItemHandle (output_control) ...................... serialized_item ↦ handle
  Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_variation_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

train_variation_model

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_variation_model

See also

read_variation_model, write_variation_model

Module

train_variation_model ( Images : ModelID : )

Train a variation model.

train_variation_model trains the variation model that is passed in ModelID with one or more images, which are passed in Images.

As described for create_variation_model, a variation model that has been created using the mode 'standard' can be trained iteratively, i.e., as soon as images of good objects become available, they can be trained with train_variation_model. The ideal image of the object is computed as the mean of all previous training images and the images that are passed in Images. The corresponding variation image is computed as the standard deviation of the training images and the images that are passed in Images.

If the variation model has been created using the mode 'robust', the model cannot be trained iteratively, i.e., all training images must be accumulated using concat_obj and be trained with train_variation_model in a single call. If any images have been trained previously, the training information of the previous call is discarded.

The image of the ideal object is computed as the median of all training images passed in Images. The corresponding variation image is computed as a suitably scaled median absolute deviation of the training images and the median image.

Attention

At most 65535 training images can be trained.
16.5. VARIATION MODEL

Parameters

- **Images** (input_object) ........................................singlechannelimage(array) \~ object : byte / int2 / uint2
  Images of the object to be trained.
- **ModelID** (input_control) ..........................................variation_model \~ handle
  ID of the variation model.

Example

```plaintext
open_framegrabber ('File', 1, 1, 0, 0, 0, 0, 'default', -1, \n'default', -1, 'default', 'model.seq', 'default', \n-1, -1, AcqHandle)
grab_image (Image, AcqHandle)
get_image_pointer1 (Image, Pointer, Type, Width, Height)
dev_display (Image)
draw_region (Region, WindowHandle)
reduce_domain (Image, Region, ImageReduced)
area_center (Region, Area, RowRef, ColumnRef)
create_shape_model (ImageReduced, 4, 0, rad(360), rad(1), 'none', \n'use_polarity', 40, 10, TemplateID)
create_variation_model (Width, Height, Type, 'standard', ModelID)
for K := 1 to 100 by 1
  grab_image (Image, AcqHandle)
  find_shape_model (Image, TemplateID, 0, rad(360), 0.5, 1, 0.5, \n    'true', 4, 0.9, Row, Column, Angle, Score)
  if (|Score| == 1)
    vector_angle_to_rigid (Row, Column, Angle, RowRef, \n      ColumnRef, 0, HomMat2D)
    affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', \n      'false')
    train_variation_model (ImageTrans, ModelID)
  endif
endfor
prepare_variation_model (ModelID, 10, 4)
write_region (Region, 'model.reg')
write_shape_model (TemplateID, 'model.shm')
write_variation_model (ModelID, 'model.var')
close_framegrabber (AcqHandle)
```

Result

train_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Chapter 17

Legacy

17.1 2D Metrology

`copy_metrology_object ( : : MetrologyHandle, Index : CopiedIndices )`

Copy metrology metrology objects of a metrology model.

`copy_metrology_object` is obsolete and is only provided for reasons of backward compatibility.

`copy_metrology_object` copies metrology metrology objects within this metrology model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle `MetrologyHandle`. The parameter `Index` determines the metrology objects that are copied. With `Index` set to 'all', all metrology objects are copied. The operator `copy_metrology_object` returns the index of the new created metrology objects in the parameter `CopiedIndices`. The order of the new metrology objects corresponds to the order of the original metrology objects. Access to the parameters of the metrology objects of the metrology model is possible, e.g., with the operator `get_metrology_object_param`.

Parameters

- `MetrologyHandle` (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . metrology_model -> handle
  Handle of the metrology model.
- `Index` (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer(-array) -> string / integer
  Index of the metrology objects.
  Default value: 'all'
  Suggested values: Index ∈ {'all', 0, 1, 2}
- `CopiedIndices` (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . integer(-array) -> integer
  Indices of the copied metrology objects.

If the parameters are valid, the operator `copy_metrology_object` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology
**transform_metrology_object** ( : : MetrologyHandle, Index, Row, Column, Phi, Mode : )

Transform metrology objects of a metrology model, e.g. for alignment.

**transform_metrology_object** is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **align_metrology_model** instead.

**transform_metrology_object** translates and rotates the metrology objects contained in **MetrologyHandle** specified by the index **Index** according to the parameters **Row**, **Column**, and **Phi**.

For an explanation of the concept of 2D metrology see the introduction of chapter **2D Metrology**.

The index **Index** refer to the index returned by the operators **add_metrology_object_circle_measure**, **add_metrology_object_ellipse_measure**, **add_metrology_object_line_measure**, or **add_metrology_object_rectangle2_measure**. **Index** may contain a single value or a tuple of values. If all metrology objects shall be transformed, **Index** can be set to ‘all’.

The parameter **Mode** can be set to ‘absolute’ or ‘relative’ and specifies the effect of the transformation:

- **Mode** = ‘absolute’: The metrology objects are translated to the image coordinates **Row** and **Column** and rotated by **Phi** with respect to the image coordinate system.
  
  For metrology objects of the type ellipse, or rectangle, the origin of the rotation is defined in the center of the metrology object as specified in the operators **add_metrology_object_ellipse_measure** or **add_metrology_object_rectangle2_measure**. For lines and circles, **Phi** is ignored.

- **Mode** = ‘relative’: The values of the transformation are considered as relative values, i.e., they are specified relative to the previous position and rotation of the metrology object.
  
  For metrology objects of the type ellipse, or rectangle, the origin of the rotation is defined in the center of the metrology object as specified in the operators **add_metrology_object_ellipse_measure**, or **add_metrology_object_rectangle2_measure**. For lines, the starting point of the line is used as origin of the rotation. For circles, **Phi** is ignored.

**transform_metrology_object** is fastest if no rotation is defined, the original and translated measure regions both lie completely within the image. In all other cases, the measure regions have to be newly generated, which is slower.

**Attention**

Note that any results (fitted geometric shapes) that have been generated by the operator **apply_metrology_model** before calling **transform_metrology_object** are discarded during the transformation.

### Parameters

- **MetrologyHandle** (input_control) .......................... metrology_model  \( \sim handle \)
  Handle of the metrology model.

- **Index** (input_control) .......................... integer(-array)  \( \sim string / integer \)
  Index of the metrology objects.

  **Default value**: ‘all’

  **Suggested values**: Index \( \in \) {‘all’, 0, 1, 2}

- **Row** (input_control) .......................... real(-array)  \( \sim real / integer \)
  Translation in row direction.

- **Column** (input_control) .......................... real(-array)  \( \sim real / integer \)
  Translation in column direction.

- **Phi** (input_control) .......................... real(-array)  \( \sim real / integer \)
  Rotation angle.

- **Mode** (input_control) .......................... string(-array)  \( \sim string \)
  Mode of the transformation.

  **Default value**: ‘absolute’

  **Suggested values**: Mode \( \in \) {‘absolute’, ‘relative’}

### Result

If the parameters are valid, the operator **transform_metrology_object** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information
17.2 Classification

**clear_sampset** ( : : SampKey : )

Free memory of a data set.

**clear_sampset** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**clear_sampset** frees the memory which was used for training data set having read by **read_sampset**. This memory is only reusable in combination with **read_sampset**.

</tr>
</tbody>
</table>

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **SampKey**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

**create_class_box, enquire_class_box, learn_class_box, write_class_box**

**See also**

**test_sampset_box, learn_sampset_box, read_sampset**

**Foundation**

**close_class_box** ( : : ClassifHandle : )

Destroy the classifier.

**close_class_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.
close_class_box deletes the classifier and frees the used memory space. All the trained data will be lost. For saving this trained data you should use write_class_box before.

Parameters

▷ ClassifHandle (input_control) .............................. class_box ~> handle
  Handle of the classifier.

Result
close_class_box returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

  • ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_class_box, enquire_class_box, learn_class_box, write_class_box

See also

create_class_box, enquire_class_box, learn_class_box

Module

Foundation

create_class_box (:: : :: ClassifHandle )

Create a new classifier.

create_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

create_class_box creates a new adaptive classifier. All operators which are explained in chapter classification refer to such a initialized classifier (of type 2). See learn_class_box for more details about the functionality of the classifier.

Parameters

▷ ClassifHandle (output_control) .............................. class_box ~> handle
  Handle of the classifier.

Result
create_class_box returns 2 (H_MSG_TRUE) if the parameter is correct. An exception is raised if a classifier with this name already exists or there is not enough memory.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

learn_class_box, enquire_class_box, write_class_box, close_class_box, clear_sampset
17.2. CLASSIFICATION

learn_class_box, enquire_class_box, close_class_box

Module Foundation

descript_class_box ( : :  ClassifHandle,  Dimensions : :  ClassIdx, BoxIdx, BoxLowerBound, BoxHigherBound, BoxNumSamplesTrain, BoxNumSamplesWrong )

Describe the classes of a box classifier.

descript_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

descript_class_box describes the classes of a box classifier. A box classifier uses a set of hypercuboids (boxes) for every class. These boxes describe the distribution of the samples.

descript_class_box returns for every class (ClassIdx) the boundaries of every contained box (BoxIdx) from dimension 1 up to Dimensions (BoxLowerBound, BoxHigherBound) as well as the number of samples that were used during the learning phase to determine these boundaries at each dimension (BoxNumSamplesTrain). Furthermore, the number of samples that were assigned to the wrong class during the learning phase is returned in BoxNumSamplesWrong.

The boundary information of the boxes can be used to inspect the box classifier.

Parameters

> ClassifHandle (input_control) .......................... handle
Handle of the classifier.

> Dimensions (input_control) .............................. integer  ~>  integer
Highest dimension for output.
Default value: 3

> ClassIdx (output_control) .............................. integer(-array)  ~>  integer
Indices of the classes.

> BoxIdx (output_control) .............................. integer(-array)  ~>  integer
Indices of the boxes.

> BoxLowerBound (output_control) ........................ integer(-array)  ~>  integer
Lower bounds of the boxes (for each dimension).

> BoxHigherBound (output_control) ........................ integer(-array)  ~>  integer
Higher bounds of the boxes (for each dimension).

> BoxNumSamplesTrain (output_control) ........................ integer(-array)  ~>  integer
Number of training samples that were used to define this box (for each dimension).

> BoxNumSamplesWrong (output_control) ........................ integer(-array)  ~>  integer
Number of training samples that were assigned incorrectly to the box.

Result

descript_class_box returns 2 (H_MSG_TRUE).

Execution Information

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

HALCON 20.11.0.0
**deserialize_class_box** ( : : ClassifHandle, SerializedItemHandle : )

Deserialize a serialized classifier.

**deserialize_class_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**deserialize_class_box** deserializes a classifier, that was serialized by **serialize_class_box** (see **fwrite_serialized_item** for an introduction of the basic principle of serialization). The serialized classifier is defined by the handle **SerializedItemHandle**. The values of the current classifier, defined by the handle **ClassifHandle**, are overwritten.

---

**Attention**

All values of the classifier are going to be overwritten.

---

**Parameters**

▷ **ClassifHandle** (input_control) : : class_box handle

Handle of the classifier.

▷ **SerializedItemHandle** (input_control) : : serialized_item handle

Handle of the serialized item.

---

**Result**

If the parameters are valid, the operator **deserialize_class_box** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**enquire_class_box** ( : : ClassifHandle, FeatureList : : Class )

Classify a tuple of attributes.

**enquire_class_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**FeatureList** is a tuple of any floating point- or integer numbers (attributes) which has to be assigned to a class with assistance of a previous trained (**learn_class_box**) classifier. It is possible to specify attributes as unknown by indicating the symbol ‘∗’ instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until ’max’, are automatically supposed to be undefined.

See **learn_class_box** for more details about the functionality of the classifier.
You may call the operators `learn_class_box` and `enquire_class_box` alternately, so that it is possible to classify already in the phase of learning. This means you could see when a satisfying behavior had been reached.

---

**Parameters**

- **ClassifHandle** (input_control) .......................................................... `class_box` ~ handle
  Handle of the classifier.

- **FeatureList** (input_control) .......................................................... `real-array` ~ `real / integer / string`
  Array of attributes which has to be classified.
  Default value: 1.0

- **Class** (output_control) .......................................................... `integer` ~ `integer`
  Number of the class to which the array of attributes had been assigned.

---

`enquire_class_box` returns 2 (H_MSG_TRUE).

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Possible Predecessors**

- `create_class_box`, `learn_class_box`, `set_class_box_param`

**Possible Successors**

---

**Module**

**Foundation**

---

```cpp
enquire_reject_class_box ( : : ClassifHandle,
    FeatureList : Class )
```

Classify a tuple of attributes with rejection class.

`enquire_reject_class_box` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

**FeatureList** is a tuple of any floating point- or integer numbers (attributes) which has to be assigned to a class with assistance of a previous trained (`learn_class_box`) classifier. It is possible to specify attributes as unknown by indicating the symbol ’*’ instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until ’max’, are automatically supposed to be undefined.

If the array of attributes cannot be assigned to a class, i.e. the array does not reside inside of one of the hyper boxes, then in contrary to `enquire_class_box` not the next class is going to be returned, but the rejection class -1 as a result is going to be passed.

See `learn_class_box` for more details about the functionality of the classifier.

You may call the operators `learn_class_box` and `enquire_class_box` alternately, so that it is possible to classify already in the phase of learning. By this means you could see when a satisfying behavior had been reached.

---

**Parameters**

- **ClassifHandle** (input_control) .......................................................... `class_box` ~ handle
  Handle of the classifier.

- **FeatureList** (input_control) .......................................................... `real-array` ~ `real / integer / string`
  Array of attributes which has to be classified.
  Default value: 1.0
> **Class** (output_control) .............................................................. integer ⇔ integer
> Number of the class, to which the array of attributes had been assigned or -1 for the rejection class.

Result

enquire_reject_class_box returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_class_box, learn_class_box, set_class_box_param

Possible Successors

learn_class_box, write_class_box, close_class_box

enquire_class_box

See also

test_sampset_box, learn_class_box, learn_sampset_box

Module

Foundation

```c
get_class_box_param ( : : ClassifHandle, Flag : Value )
```

Get information about the current parameter.

get_class_box_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

get_class_box_param gets the parameter of the classifier. The meaning of the parameter is explained in set_class_box_param.

Default values:

- 'min_samples_for_split' = 80,
- 'split_error' = 0.1,
- 'prop_constant' = 0.25

Parameters

- **ClassifHandle** (input_control) .............................................. class_box ⇔ handle
  Handle of the classifier.
- **Flag** (input_control) ......................................................... string ⇔ string
  Name of the system parameter.

  Default value: 'split_error'

  List of values: Flag ∈ {'split_error', 'prop_constant', 'used_memory', 'min_samples_for_split'}
- **Value** (output_control) ..................................................... number ⇔ real / integer
  Value of the system parameter.

Result

get_class_box_param returns 2 (H_MSG_TRUE). An exception is raised if Flag has been set with wrong values.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
Train the classifier.

`learn_class_box` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`Features` is a tuple of any floating point numbers or integers (attributes) which has to be assigned to the class `Class`. This class is specified by an integer. You may use the operator `enquire_class_box` later to find the most probable class for any array (=tuple). The algorithm tries to describe the set of arrays of one class by hypercuboids in the feature space. On demand you may even create several cuboids per class. Hence it is possible to learn disjunct concepts, too. I.e such concepts which split in several “cluster” of points in the feature space. The data structure is hidden to the user and only accessible with such operators which are described in this chapter.

Note that if a class consists of disjunct sub-classes that would lead to a splitting of the respective hyper cuboid, the training samples should be in random order with respect to the sub-classes. Otherwise, the splitting of the hyper cuboid will be sub-optimal.

It is possible to specify attributes as unknown by indicating the symbol ‘*’ instead of a number. If you specify `n` values, then all following values, i.e. the attributes `n+1` until ‘max’, are automatically supposed to be undefined.

You may call the operators `learn_class_box` and `enquire_class_box` alternately, so that it is possible to classify already in the phase of learning. By this means you could see when a satisfying behavior had been reached.

The classifier is going to be bigger using further training. This means, that it is not advisable to continue training after reaching a satisfactory behavior.

### Parameters

- **ClassifHandle** (input_control) class_box \(\rightsquigarrow\) `handle` Handle of the classifier.
- **Features** (input_control) number-array \(\rightsquigarrow\) `real` / `integer` / `string` Array of attributes to learn.
  - **Default value:** `[1.0, 1.5, 2.0]`
- **Class** (input_control) integer \(\rightsquigarrow\) `integer` Class to which the array has to be assigned.
  - **Default value:** `1`

### Result

`learn_class_box` returns 2 (H_MSG_TRUE) for a normal case. An exception is raised if there are memory allocation problems. The number of classes is constrained. If this limit is passed, an exception is raised, too.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ClassifHandle**
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module
Foundation

**learn_sampset_box** ( : : ClassifHandle, SampKey, Outfile, NSamples, StopError, ErrorN : )

*Train the classifier with one data set.*

*learn_sampset_box* is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

*learn_sampset_box* trains the classifier with the key *SampKey* (see *read_sampset*). The training sequence is terminated at least after *NSamples* examples. If *NSamples* is bigger than the number of examples in *SampKey*, then a cyclic start at the beginning occurs. If the error underpasses the value *StopError*, then the training sequence is prematurely terminated. *StopError* is calculated with *N / ErrorN*. Whereby *N* means the number of examples which were wrong classified during the last *ErrorN* training examples. Typically *ErrorN* is the number of examples in *SampKey* and *NSamples* is a multiple of it. If you want a data set with 100 examples to run 5 times at most and if you want it to terminate with an error lower than 5%, then the corresponding values are *NSamples = 500, ErrorN = 100* and *StopError = 0.05*. A protocol of the training activity is going to be written in file *Outfile*.

**Parameters**

- **ClassifHandle** (input_control) .............................................. class_box ~ handle
  Handle of the classifier.

- **SampKey** (input_control) .................................................. feature_set ~ handle
  Number of the data set to train.

- **Outfile** (input_control) .................................................. filename.write ~ string
  Name of the protocol file.
  Default value: ‘training_prot’

- **NSamples** (input_control) ................................................. integer ~ integer
  Number of arrays of attributes to learn.
  Default value: 500

- **StopError** (input_control) .............................................. real ~ real
  Classification error for termination.
  Default value: 0.05

- **ErrorN** (input_control) .................................................. integer ~ integer
  Error during the assignment.
  Default value: 100

**Result**

*learn_sampset_box* returns 2 (H_MSG_TRUE). An exception is raised if key *SampKey* does not exist or there are problems while opening the file.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_class_box

Possible Successors
test_sampset_box, enquire_class_box, write_class_box, close_class_box,
clear_sampset

See also
test_sampset_box, enquire_class_box, learn_class_box, read_sampset

Module
Foundation

read_class_box (:: ClassifHandle, FileName :: )

Read a classifier from a file.

read_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

read_class_box reads the saved classifier from the file FileName (see write_class_box). The values of the current classifier are overwritten. The default HALCON file extension for the box classifier is 'gbc'.

Attention
All values of the classifier are going to be overwritten.

Parameters

▷ ClassifHandle (input_control) .............................................. class_box ↦ handle
Handle of the classifier.

▷ FileName (input_control) ................................................ filename.read ↦ string
Filename of the classifier.

File extension: .gbc

Result
read_class_box returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file FileName or the file has the wrong format.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
**read_sampset** ( : : FileName : SampKey )

Read a training data set from a file.

**read_sampset** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

The training examples are accessible with the key **SampKey** by calling the operators **clear_sampset** and **learn_sampset_box**. You may edit the file using an editor. Every row contains an array of attributes with corresponding class. An example for a format might be:

\[(1.0, 25.3, *, 17 | 3)\]

This row specifies an array of attributes which belong to class 3. In this array the third attribute is unknown. Attributes upwards 5 are supposed to be unknown, too. You may insert comments like /* .. */ in any place.

**Parameters**

- **FileName** (input_control) 
  Filename of the data set to train.
  Default value: 'sampset1'

- **SampKey** (output_control) 
  Identification of the data set to train.

**Result**

read_sampset returns 2 (H_MSG_TRUE). An exception is raised if it is not possible to open the file or it contains syntax errors or there is not enough memory.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Predecessors**

**Possible Successors**

- **test_sampset_box, enquire_class_box, write_class_box, close_class_box, clear_sampset**

**See also**

- **test_sampset_box, clear_sampset, learn_sampset_box**

**Foundation**

**serialize_class_box** ( : : ClassifHandle : SerializedItemHandle )

Serialize a classifier.

**serialize_class_box** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

HALCON/HDevelop Reference Manual, 2020-11-10
serialize_class_box serializes a classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_class_box is converted to a serialized item. The classifier is defined by the handle ClassifHandle. The serialized classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_class_box.

Parameters

- ClassifHandle (input_control) ~ handle
  Handle of the classifier.
- SerializedItemHandle (output_control) ~ handle
  Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_class_box returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_class_box, enquire_class_box, learn_class_box, test_sampset_box

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_class_box

See also

create_class_box, deserialize_class_box

Module

Foundation

set_class_box_param ( : : ClassifHandle, Flag, Value : )

Set system parameters for classification.

set_class_box_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

set_class_box_param modifies parameter which manipulate the training sequence while calling learn_class_box. Only parameters of the classifier are modified, all other classifiers remain unmodified. ‘min_samples_for_split’ is the number of examples at least which have to train in one cuboid of this classifier, before the cuboid is allowed to divide itself. ‘split_error’ indicates the critical error. By its exceeding the cuboid divides itself, if there are more than ‘min_samples_for_split’ examples to train. ‘prop_constant’ manipulates the extension of the cuboids. It is proportional to the average distance of the training examples in this cuboid to the center of the cuboid. More detailed:

extension × prop = average distance of the expectation value.

This relation is valid in every dimension. Hence inside a cuboid the dimensions of the feature space are supposed to be independent.

The parameters are set with problem independent default values, which must not modified without any reason. Parameters are only important during a learning sequence. They do not influence on the behavior of enquire_class_box.

Default setting:

- ‘min_samples_for_split’ = 80,
- ‘split_error’ = 0.1,
- ‘prop_constant’ = 0.25
Parameters

- **ClassifHandle** (input_control) .......................... class_box ↦ handle
  Handle of the classifier.
- **Flag** (input_control) .......................... string ↦ string
  Name of the wanted parameter.
  Default value: ‘split_error’
  Suggested values: Flag ∈ {‘min_samples_for_split’, ‘split_error’, ‘prop_constant’}
- **Value** (input_control) .......................... number ↦ real / integer
  Value of the parameter.
  Default value: 0.1

Result

read_sampset returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_class_box, enquire_class_box

Possible Successors

learn_class_box, test_sampset_box, write_class_box, close_class_box, clear_sampset

See also

enquire_class_box, get_class_box_param, learn_class_box

Module

Foundation

**test_sampset_box** ( : : ClassifHandle, SampKey : Error )

Classify a set of arrays.

test_sampset_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

In contrast to learn_sampset_box there is not a learning here. Typically you use test_sampset_box to classify independent test data. Error gives you information about the applicability of the learned training set on new examples.

Parameters

- **ClassifHandle** (input_control) .......................... class_box ↦ handle
  Handle of the classifier.
- **SampKey** (input_control) .......................... feature_set ↦ handle
  Key of the test data.
- **Error** (output_control) .......................... real ↦ real
  Error during the assignment.

Result

test_sampset_box returns 2 (H_MSG_TRUE). An exception is raised, if if key SampKey does not exist or problems occur while opening the file.
17.2. CLASSIFICATION

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

HALCON 20.11.0.0
17.3 Control

```
ifelse ( : : Condition : )
```

Conditional statement with alternative.

**ifelse** is obsolete and is only provided for reasons of backward compatibility. **if** should be used instead.

*ifelse* is a conditional statement with an alternative. If the condition is true (i.e., not 0), all expressions and calls between the head and operator **else** are performed. If the condition is false (i.e., 0) the part between **else** and **endif** is executed. Note that the operator is called *ifelse* and it is displayed as *if* in the program text area.

Parameters

- **Condition** (input_control) ................................................. integer  ~  integer
  
  Condition for the **if** statement.

  Default value: 1

Result

- If the condition is correct **ifelse** (as operator) returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

- **if**

See also

- **else**, **elseif**, **for**, **while**, **repeat**, **until**

17.4 DL Classification

The workflow and operators described in this chapter are obsolete and only provided for reasons backward compatibility. New applications should use the workflow and operators described in Deep Learning / Classification.

This chapter explains how to use classification based on deep learning, both for the training and inference phases.

General Workflow

This section describes the main steps and the workflow for classification with Deep Learning using the obsolete workflow.

Prepare the Network and the Data

This part is about how to prepare and preprocess your data.

1. First, a pretrained network has to be read using the operator
   - **read_dl_classifier**.
   
   This operator is used as well when you want to read your own trained networks, after you saved them with **write_dl_classifier**.

2. To read the data for your deep learning classification training the procedure
   - **read_dl_classifier_data_set**
   
   is available. Using this procedure you can get a list of image file paths and their respective labels (the ground truth labels) as well as a list of the unique classes, to which at least one of the listed images belongs.

3. The network will impose several requirements on the images, as the image dimensions and the gray value range. The default values are listed in **read_dl_classifier**. These are the values with which the networks have been pretrained. The network architectures allow different image dimensions, which can be set with **set_dl_classifier_param**, but depending on the network a change may make a retraining necessary. The actually set values can be retrieved with
17.4. DL CLASSIFICATION

• get_dl_classifier_param.

The procedure preprocess_dl_classifier_images provides great guidance on how to implement such a preprocessing stage. We recommend to preprocess and store all images used for the training before starting the classifier training, since this speeds up the training significantly.

4. Next, we recommend to split the dataset into three distinct datasets which are used for training, validation, and testing, see the section “Data” in the chapter Deep Learning. This can be achieved using the procedure

• split_dl_classifier_data_set.

5. You need to specify the ‘classes’ (determined before by use of read_dl_classifier_data_set) you want to differentiate with your classifier. For this, the operator

• set_dl_classifier_param

is available.

This operator can also be used to set hyperparameters, which are important for training, e.g., 'batch_size' and 'learning_rate'. For a more detailed explanation, see the chapter Deep Learning and the documentation of set_dl_classifier_param.

Train the Network and Evaluate the Training Progress Once your network is set up and your data prepared it is time to train the classifier for your specific task.

1. Set the hyperparameters used for training with the operator

• set_dl_classifier_param.

For an overview of possible hyperparameters, see the documentation of set_dl_classifier_param. Additional explanations can be found in the chapter Deep Learning.

2. To train the classifier the operator

• train_dl_classifier_batch

is available. The intermediate training results are stored in the output handle.

As the name of train_dl_classifier_batch indicates, this operator processes a batch of data (images and ground truth labels) at once. We iterate through our training data in order to train the classifier successively with train_dl_classifier_batch. You can repeat this process multiple times and iterate over so many training epochs until you are satisfied with the training result.

3. To know how well the classifier learns the new task, the procedure

• plot_dl_classifier_training_progress

is provided. With it you can plot the classification errors during training. To compute the input necessary for the visualization, the procedures

• select_percentage_dl_classifier_data,
• apply_dl_classifier_batchwise, and
• evaluate_dl_classifier

are available. With them you can reduce the number of images used for this classification validation, apply the classifier on the selected data and compute, for example, the top-1 error.

Apply and Evaluate the Final Classifier Your classifier is trained for your task and ready to be applied. But before deploying in the real world you should evaluate how well the classifier performs on basis of your test data.

1. To apply the classifier on a set containing an arbitrary number of images, use the operator

• apply_dl_classifier.

The runtime of this operator depends on the number of batches needed for the given image set. The results are returned in a handle.

To retrieve the predicted classes and confidences, use the operator

• get_dl_classifier_result.
2. Now it is time to evaluate these results. The performance of the classifier can be evaluated as during the training with `evaluate_dl_classifier`.

To visualize and analyze the classifier quality, the confusion matrix is a useful tool (see below for an explanation). For this, you can use the procedures

- `gen_confusion_matrix`
- `gen_interactive_confusion_matrix`.

The interactive procedure gives you the possibility to select examples of a specific category, but it does not work with exported code.

Additionally, after applying the classifier on a set of data, you can use the procedure

- `get_dl_classifier_image_results`

to display and return images according to certain criteria, e.g., wrongly classified ones. Then, you might want to use this input for the procedure

- `dev_display_dl_classifier_heatmap`

to display a heatmap of the input image, with which you can analyze which regions of the image are relevant for the classification result.

**Inference Phase** When your classifier is trained and you are satisfied with its performance, you can use it to classify new images. For this, you simply preprocess your images according to the network requirements (i.e., the same way as you did for your dataset used for training the classifier) and apply the classifier using

- `apply_dl_classifier`.

**Data for Classification**

We distinguish between data used for training and data for inference. Latter one consists of bare images. But for the former one you already know to which class the images belong and provide this information over the corresponding labels.

The training data is used to train a classifier for your specific task. With the aid of this data the classifier can learn which classes are to be distinguished and how their representatives look like. In classification, the image is classified as a whole. Therefore, the training data consists of images and their ground truth labels, thus the class you say this image belongs to. Note that the images should be as representative as possible for your task. There are different possible ways, how to store and retrieve the ground truth labels. The procedure `read_dl_classifier_data_set` supports the following sources of the ground truth label for an image:

- The last directory name containing the image
- The file name.

For training a classifier, we use a technique called transfer learning (see the chapter Deep Learning). For this, you need less resources, but still a suitable set of data which is generally in the order of hundreds to thousands per class. While in general the network should be more reliable when trained on a larger dataset, the amount of data needed for training also depends on the complexity of the task. You also want enough training data to split it into three subsets, which are preferably independent and identically distributed, see the section “Data” in the chapter Deep Learning.

Regardless of the application, the network poses requirements on the images regarding the image dimensions, the gray value range, and the type. The specific values depend on the network itself and can be queried with `get_dl_classifier_param`. You can find guidance on how to implement such a preprocessing stage by the procedure `preprocess_dl_classifier_images`.

```c
apply_dl_classifier ( Images : : DLClassifierHandle : DLClassifierResultHandle )
```

Infer the class affiliations for a set of images using a deep-learning-based classifier.

`apply_dl_classifier` is obsolete and is only provided for reasons of backward compatibility. New applications should use the general CNN-based operator `apply_dl_model` instead.
apply_dl_classifier applies the deep-learning-based classifier given by DLClassifierHandle on the set of input images stored in the input object tuple Images. It returns the results in the result handle DLClassifierResultHandle. For information how to retrieve the corresponding results stored in DLClassifierResultHandle, please refer to the documentation of the operator get_dl_classifier_result.

The tuple Images can contain an arbitrary number of images to be processed in one operator call and is generally independent of the classifier parameter 'batch_size'. Please notice that this only holds for apply_dl_classifier and not for train_dl_classifier_batch. This is because apply_dl_classifier always classifies a batch with up to 'batch_size' images simultaneously, whether filled up or not. So in case the number of images in the set Images is larger than 'batch_size', apply_dl_classifier iterates over the necessary number of batches internally. For a Images tuple with less than 'batch_size' images, it is padded to a full batch which means that the runtime of processing for a given batch is independent of whether it is filled up or just consists of a single image. Additionally, if fewer images than 'batch_size' are classified in one operator call, the network still requires the same amount of memory as for a full batch. Therefore, it is recommended to adapt the 'batch_size' according to the number of images to be processed in one operator call for greater efficiency. The current value of 'batch_size' can be retrieved using get_dl_classifier_param.

Note that the images must be processed before feeding them into the operator apply_dl_classifier in order to have the correct size, gray value range, number of channels and type. We would like to stress the image type: the images must be of type 'real'. For a possibly necessary conversion the operator convert_image_type is available. The procedure preprocess_dl_classifier_images provides great guidance on how to implement such a preprocessing stage.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Attention

To run this operator, cuDNN and cuBLAS are required when 'runtime' is set to 'gpu', see set_dl_classifier_param. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

- **Images** (input_object) ...........................(multichannel-)image-array) ～ object : real
  Tuple of input images.
- **DLClassifierHandle** (input_control) ........................dl_classifier ～ handle
  Handle of the deep-learning-based classifier.
- **DLClassifierResultHandle** (output_control) ........................dl_classifier_result ～ handle
  Handle of the deep learning classification results.

Result

If the parameters are valid, the operator apply_dl_classifier returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

read_dl_classifier, train_dl_classifier_batch, set_dl_classifier_param

Possible Successors

get_dl_classifier_result, clear_dl_classifier

Alternatives

apply_dl_model, classify_class_mlp, classify_class_svm

Module

Deep Learning Inference
clear_dl_classifier ( : : DLClassifierHandle : )

Clear a deep-learning-based classifier.

clear_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common used CNN-based operator clear_dl_model instead.

clear_dl_classifier clears the handle of the deep-learning-based classifier given by DLClassifierHandle, that was created with read_dl_classifier, and frees all memory required for the classifier. After calling clear_dl_classifier, the classifier can no longer be used. The handle DLClassifierHandle becomes invalid.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

⊿ DLClassifierHandle (input_control) ......................... dl_classifier(-array) ~ handle
Handle of the deep-learning-based classifier.

Result

If the parameters are valid, the operator clear_dl_classifier returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• DLClassifierHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

read_dl_classifier, apply_dl_classifier, train_dl_classifier_batch

Module

Deep Learning Inference

clear_dl_classifier_result ( : : DLClassifierResultHandle : )

Clear a handle containing the results of the deep-learning-based classification.

clear_dl_classifier_result is obsolete and is only provided for reasons of backward compatibility.

clear_dl_classifier_result releases the memory used to store the deep-learning-based classification results given in DLClassifierResultHandle. After calling clear_dl_classifier_result, the results can no longer be queried. The handle DLClassifierResultHandle becomes invalid.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
17.4. DL CLASSIFICATION

**Parameters**

- **DLClassifierResultHandle (input_control)**: Handle of the deep learning classification results.

**Result**

If the parameters are valid, the operator `clear_dl_classifier_result` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `get_dl_classifier_result`, `apply_dl_classifier`

**Module**

Deep Learning Inference

```c
void clear_dl_classifier_result(
  : DLClassifierResultHandle :);
```

Clear the handle of a deep-learning-based classifier training result.

`clear_dl_classifier_train_result` is obsolete and is only provided for reasons of backward compatibility.

`clear_dl_classifier_train_result` clears an arbitrary number of training result handles `DLClassifierTrainResultHandle` of a deep-learning-based classifier. Each of these training result handles has previously been generated using `train_dl_classifier_batch`. All memory allocated in the handles is freed.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

**Parameters**

- **DLClassifierTrainResultHandle (input_control)**: Handle of the training results from the deep-learning-based classifier.

**Result**

If the parameters are valid, the operator `clear_dl_classifier_train_result` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `train_dl_classifier_batch`, `get_dl_classifier_train_result`

**Module**

Deep Learning Training

```c
void deserialize_dl_classifier(
  : SerializedItemHandle : DLClassifierHandle );
```

Deserialize a deep-learning-based classifier.
deserialize_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator deserialize_dl_model.

deserialize_dl_classifier deserializes a deep-learning-based classifier, that was serialized by serialize_dl_classifier.

The operator acts the same as read_dl_classifier except that the input is a serialized item instead of a file. For a detailed description please refer to the documentation of read_dl_classifier.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

- **SerializedItemHandle** (input_control) serialized_item \( \rightarrow \) handle
  - Handle of the serialized item.
- **DLClassifierHandle** (output_control) dl_classifier \( \rightarrow \) handle
  - Handle of the deep-learning-based classifier.

Result

If the parameters are valid, the operator deserialize_dl_classifier returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_dl_classifier

Possible Successors

apply_dl_classifier, train_dl_classifier_batch, set_dl_classifier_param, get_dl_classifier_param

Alternatives

deserialize_dl_model

Module

Deep Learning Inference

get_dl_classifier_param ( : : DLClassifierHandle,
                          GenParamName : GenParamValue )

Return the parameters of a deep-learning-based classifier.

get_dl_classifier_param is obsolete and is only provided for reasons of backward compatibility. New applications should use common CNN-based operator get_dl_model_param instead.

get_dl_classifier_param returns the parameter values GenParamValue of GenParamName of the neural network DLClassifierHandle.

The hyperparameters and network parameters can be set with the operator set_dl_classifier_param, in whose reference entry they are described in detail. With get_dl_classifier_param you can query all these values.

Additionally, there are parameters defined by the network which are read-only. These parameters are:

- ‘image_range_min’: Minimum gray value.
- ‘image_range_max’: Maximum gray value.
17.4. DL CLASSIFICATION

The precise values for these parameters and the default parameters for the image dimension depend on the concrete network, see `read_dl_classifier`.

Every image that is fed into the network must be present according to the parameters defining the image properties. To preprocess images accordingly, the procedure `preprocess_dl_classifier_images` is available.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

--- Parameters ---

- **DLClassifierHandle** *(input_control)*
  - **dl_classifier** ~ handle
  - Handle of the deep-learning-based classifier.

- **GenParamName** *(input_control)*
  - **attribute.name(-array)** ~ string
  - Name of the generic parameter.
  - **Default value:** 'gpu'
  - **List of values:** GenParamName ∈ ['batch_size', 'batch_size_multiplier', 'classes', 'gpu', 'image_dimensions', 'image_num_channels', 'image_height', 'image_range_max', 'image_range_min', 'image_width', 'learning_rate', 'momentum', 'runtime', 'runtime_init', 'weight_prior']

- **GenParamValue** *(output_control)*
  - **attribute.name(-array)** ~ integer / string / real
  - Value of the generic parameter.

--- Result ---

If the parameters are valid, the operator `get_dl_classifier_param` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

--- Execution Information ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Possible Predecessors ---

- `set_dl_classifier_param`

--- Module ---

Deep Learning Inference

---

**get_dl_classifier_result** ( : : DLClassifierResultHandle, Index, GenResultName : GenResultValue )

Retrieve classification results inferred by a deep-learning-based classifier.

**get_dl_classifier_result** is obsolete and is only provided for reasons of backward compatibility.

`get_dl_classifier_result` allows the user to return classification results. These results are stored in the handle `DLClassifierResultHandle` and have been obtained from the operator `apply_dl_classifier`.

The input parameter `GenResultName` names the sort of result asked and `Index` identifies for which image the result is to be returned. The respective value is given in `GenResultValue`.

Concretely, `GenResultName` can attain the following values:

- 'confidences': return the confidences values for the selected image `Index`.
'predicted_classes': return the names of the inferred classes for the selected image Index.  
'predicted_class_indices': return the indices of the inferred classes for the selected image Index. The class indices correspond to the positions within the array of classes (counting from 0).  

The input parameter Index can attain the value 'all', in which case get_dl_classifier_result returns the confidence value, respectively class, for the best candidate (prediction with the highest confidence value) for each image of the input batch.  
Otherwise, Index must be an integer selecting one of the input images in the batch, in which case get_dl_classifier_result returns all output classes, respectively, confidences sorted by decreasing confidence value. This is useful in order to retrieve the best K candidates for a given input. As we start indexing at 0, Index must have a value between 0 and the size of the batch of input images minus one.  

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.  

Parameters

- **DLClassifierResultHandle** (input_control) ................. dl_classifier_result ↷ handle  
  Handle of the deep learning classification results.  
- **Index** (input_control) ................................................... number ↷ string / integer  
  Index of the image in the batch.  
  Default value: 'all'  
- **GenResultName** (input_control) ................................. attribute.name(-array) ↷ string  
  Name of the generic parameter.  
  Default value: 'predicted_classes'  
  List of values: GenResultName ∈ ['predicted_classes', 'predicted_class_indices', 'confidences']  
- **GenResultValue** (output_control) ......................... attribute.value(-array) ↷ real / string / integer  
  Value of the generic parameter, either the confidence values, the class names or class indices.  

Result  
If the parameters are valid, the operator get_dl_classifier_result returns the value 2 (H_MSG_TRUE).  
If necessary, an exception is raised.  

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).  
- Multithreading scope: global (may be called from any thread).  
- Processed without parallelization.  

Possible Predecessors

- apply_dl_classifier  

Possible Successors

- clear_dl_classifier_result  

Module

Deep Learning Inference

get_dl_classifier_train_result {  
  : : DLClassifierTrainResultHandle, GenParamName : GenParamValue }  

Return the results for the single training step of a deep-learning-based classifier.  
get_dl_classifier_train_result is obsolete and is only provided for reasons of backward compatibility.  
get_dl_classifier_train_result returns the value GenParamValue of the result GenParamName of a deep learning training handle DLClassifierTrainResultHandle.  

The options for GenParamValue are the following:
'loss' or 'total_loss': Current value of the loss function. See train_dl_classifier_batch for a detailed explanation of the loss function.

'mll_loss': Current value of the loss function, i.e. 'loss', without 'regularization_loss'.

'regularization_loss': Current value of the regularization loss function, i.e. 'loss' without 'mll_loss'.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

- DLClassifierTrainResultHandle (input_control) . . . . . . . . . . . . . dl_classifier_train_result ~ handle
  Handle of the training results from the deep-learning-based classifier.

- GenParamName (input_control) . . . . . . . . . . . . . . . . . . . . . attribute.name(-array) ~ string
  Name of the generic parameter.

  Default value: 'loss'

  List of values: GenParamName ∈ {'loss', 'mll_loss', 'regularization_loss', 'total_loss'}

- GenParamValue (output_control) . . . . . . . . . . . . . . . . . . . . . attribute.name(-array) ~ real / integer / string
  Value of the generic parameter.

Result

If the parameters are valid, the operator get_dl_classifier_train_result returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

train_dl_classifier_batch

Possible Successors

clear_dl_classifier_train_result

Module

Deep Learning Training

read_dl_classifier ( : : FileName : DLClassifierHandle )

Read a deep-learning-based classifier from a file.

read_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator read_dl_model.

The operator read_dl_classifier reads a neural network written by write_dl_classifier. As a result, the handle DLClassifierHandle is returned.

HALCON provides pretrained neural networks. These neural networks are good starting points to train a custom classifier for image classification. They have been pretrained on a large image dataset. The provided pretrained neural networks are:

'pretrained_dl_classifier_compact.hdl': This neural network is designed to be memory and runtime efficient.

This classifier expects the images to be of the type 'real'. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with get_dl_classifier_param. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
This network does not contain any fully connected layer. The network architecture allows changes concerning the image dimensions, but requires a minimum 'image_width' and 'image_height' of 15 pixels.

'pretrained_dl_classifier_enhanced.hdl': This neural network has more hidden layers than 'pretrained_dl_classifier_compact.hdl' and is therefore assumed to be better suited for more complex classification tasks. But this comes at the cost of being more time and memory demanding. As a result, e.g., in comparison to the above compact network, the batch size has to be decreased network during the training, see set_dl_classifier_param.

This classifier expects the images to be of the type 'real'. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with get_dl_classifier_param. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127
'image_range_max': 128

The network architecture allows changes concerning the image dimensions, but requires a minimum 'image_width' and 'image_height' of 47 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Changing the image size will reinitialize the weights of the fully connected layers and therefore makes a retraining necessary.

'pretrained_dl_classifier_resnet50.hdl': As the neural network 'pretrained_dl_classifier_enhanced.hdl', this classifier is suited for more complex tasks. But its structure differs, bringing the advantage of making the training more stable and being internally more robust.

This classifier expects the images to be of the type 'real'. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with get_dl_classifier_param. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127
'image_range_max': 128

The network architecture allows changes concerning the image dimensions, but a minimum 'image_width' and 'image_height' of 32 pixels is recommended. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Despite the fully connected layer a change of the image size does not lead to a reinitialization of the weights.

The values listed above are the default image dimensions and gray value range for the networks and these are the values with which the classifiers have been trained. The network architectures allow different image sizes which can be set with set_dl_classifier_param. For networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained are likely to show a reduced classification accuracy.

The actually configured dimensions can be queried by get_dl_classifier_param. Every image that is fed into a network must be present according to the required dimensions. To adjust images accordingly, the procedure preprocess_dl_classifier_images is available.

Typically it is easier, faster and better to retrain a pretrained classifier for a given classification problem. A pretrained classifier has already learned good general purpose features. To retrain the network for a custom problem, the new 'classes' of the classifier have to be set with set_dl_classifier_param.

The neural network is loaded from the file FileName. This file is hereby searched in the directory ($HALCON-ROOT/dl/) as well as in the currently used directory.

Please note that the runtime specific parameter 'gpu' of the classifier is not read from file. Instead it is initialized with its default value (see set_dl_classifier_param).

The default HALCON file extension for deep learning classifiers is '.hdl'.
For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

− FileName (input_control) ................................................. .filename.read  \( \sim \) string
  File name.
  Default value: 'pretrained_dl_classifier_compact.hdl'
  List of values: FileName \( \in \) ['pretrained_dl_classifier_compact.hdl', 'pretrained_dl_classifier_enhanced.hdl', 'pretrained_dl_classifier_resnet50.hdl']
  File extension: .hdl
− DLClassifierHandle (output_control) .................................... dl_classifier  \( \sim \) handle
  Handle of the deep learning classifier.

Result

If the indicated file is available and the format is correct, the operator read_dl_classifier returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_dl_classifier_param, get_dl_classifier_param, apply_dl_classifier, train_dl_classifier_batch

Alternatives

read_dl_model, read_class_mlp, read_class_svm

Module

Deep Learning Inference

serialize_dl_classifier ( : : DLClassifierHandle : SerializedItemHandle )

Serialize a deep-learning-based classifier.

serialize_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator serialize_dl_model.

serialize_dl_classifier serializes a deep-learning-based classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The classifier is defined by the handle DLClassifierHandle. The serialized classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_dl_classifier.

The operator acts the same as write_dl_classifier except that the output is a serialized item instead of a file. For a detailed description please refer to the documentation of write_dl_classifier.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Parameters

− DLClassifierHandle (input_control) .................................... dl_classifier  \( \sim \) handle
  Handle of the deep-learning-based classifier.
− SerializedItemHandle (output_control) .................................. serialized_item  \( \sim \) handle
  Handle of the serialized item.
Result

If the parameters are valid, the operator serialize_dl_classifier returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- train_dl_classifier_batch

Possible Successors

- apply_dl_classifier, train_dl_classifier_batch, fwrite_serialized_item, set_dl_classifier_param, get_dl_classifier_param

Alternatives

- serialize_dl_model

- deserialize_dl_classifier, apply_dl_classifier, train_dl_classifier_batch

Module

Deep Learning Inference

| set_dl_classifier_param | : : DLClassifierHandle, GenParamName, GenParamValue : | }

Set the parameters of a deep-learning-based classifier.

set_dl_classifier_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator set_dl_model_param instead.

set_dl_classifier_param sets the parameters and hyperparameters GenParamName of the neural network DLClassifierHandle to the values GenParamValue.

The pretrained classifiers are trained for their default image dimensions, see read_dl_classifier.

The network architectures allow different image dimensions. But for networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained, are likely to show a reduced classification accuracy.

GenParamName can attain the following values:

- **'batch_size'**: Number of images (and corresponding labels) in a batch that is transferred to device memory. The batch of images which are processed simultaneously in a single training iteration contains a number of images which is equal to 'batch_size' times 'batch_size_multiplier'. Please refer to train_dl_classifier_batch for further details. The parameter 'batch_size' is stored in the pretrained classifier. Per default, the 'batch_size' is set such that a training of the pretrained classifier with up to 100 classes can be easily performed on a device with 8 gigabyte of memory. For the pretrained classifiers, the default values are hence given as follows:

<table>
<thead>
<tr>
<th>pretrained classifier</th>
<th>default value of 'batch_size'</th>
</tr>
</thead>
<tbody>
<tr>
<td>'pretrained_dl_classifier_compact.hdl'</td>
<td>160</td>
</tr>
<tr>
<td>'pretrained_dl_classifier_enhanced.hdl'</td>
<td>96</td>
</tr>
<tr>
<td>'pretrained_dl_classifier_resnet50.hdl'</td>
<td>23</td>
</tr>
</tbody>
</table>

For inference, the 'batch_size' can be generally set independently from the number of input images. See apply_dl_classifier for details on how to set this parameter for greater efficiency.

- **'batch_size_multiplier'**: Multiplier for 'batch_size' to enable training with larger numbers of images in one step which would otherwise not be possible due to GPU memory limitations. For detailed information see train_dl_classifier_batch. This model parameter does not have any impact during evaluation and inference. For the pretrained classifiers, the default value of 'batch_size_multiplier' is set to 1.
17.4. DL CLASSIFICATION

'classes': Tuple of labels corresponding to the classes of objects which are to be recognized. The order of the class names remains unchanged after the setting.

'gpu': Identifier of the GPU where the training and inference operators (train_dl_classifier_batch and apply_dl_classifier) are executed. Per default, the first available GPU is used. get_system with 'cuda_devices' can be used to retrieve a list of available GPUs. Pass the index in this list to 'gpu'.

'image_width': Width of the images the network will process. The default value is given by the network, see read_dl_classifier.

'image_height': Height of the images the network will process. The default value is given by the network, see read_dl_classifier.

'image_num_channels': Number of channels of the images the network will process. Possible are one channel (gray value image), or three channels (three-channel image). The default value is given by the network, see read_dl_classifier. Changing to a single channel image modifies the network configuration. This process removes the color information contained in certain layers and is not invertible.

'image_dimensions': Tuple containing the image dimensions 'image_width', 'image_height', and number of channels 'image_num_channels'. The default values are given by the network, see read_dl_classifier. Concerning the number of channels, the values one (gray value image), or three (three-channel image) are possible. Changing to a single channel image modifies the network configuration. This process removes the color information contained in certain layers and is not invertible.

'learning_rate': Initial value of the factor determining the gradient influence during training. Please refer to train_dl_classifier_batch for further details. The default value depends on the classifier.

'momentum': When updating the arguments of the loss function, the hyperparameter 'momentum' specifies to which extent previous updating vectors will be added to the current updating vector. Please refer to train_dl_classifier_batch for further details. The default value depends on the classifier.

'runtime': Defines the device on which the operators will be executed. Per default, the 'runtime' is set to 'gpu'.

'cpu': The operator apply_dl_classifier will be executed on the CPU, whereas the operator train_dl_classifier_batch is not executable.

In case the GPU has been used before, CPU memory is initialized, and if necessary values stored on the GPU memory are moved to the CPU memory.

On Intel or AMD architectures the 'cpu' runtime uses OpenMP for the parallelization of apply_dl_classifier, where per default, all threads available to the OpenMP runtime are used. You may use the set_system parameter 'tsp_thread_num' to specify the number of threads.

On Arm architectures the 'cpu' runtime uses a global thread pool. You may specify the number of threads with the set_system parameter 'thread_num'. You cannot specify a thread specific number of threads on Arm architectures.

'gpu': The GPU memory is initialized and the corresponding handle created. The operators apply_dl_classifier and train_dl_classifier_batch will be executed on the GPU.

For the specific requirements please refer to the HALCON "Installation Guide".

'runtime_init': If called with 'immediately', the GPU memory is initialized and the corresponding handle created. Otherwise this is done on demand, which may result in significantly larger execution times for the first call of apply_dl_classifier or train_dl_classifier_batch. If 'gpu' or 'batch_size' is changed with subsequent calls of set_dl_classifier_param, the GPU memory is reinitialized.

Note, this parameter has no effect if running on CPUs, thus if 'runtime' is set to 'cpu'.

'weight_prior': Regularization parameter \( \alpha \geq 0.0 \) used for \( l_2 \) regularization of the loss function. Regularization is helpful in the presence of overfitting during the classifier training. If the hyperparameter 'weight_prior' is non-zero, the regularization term given below is added to the loss function (see also train_dl_classifier_batch)

\[
E_\alpha(w) = \frac{\alpha}{2} \sum_{k=0}^{K-1} |w_k|^2
\]

Here the index \( k \) runs over all weights of the network, except for the biases which are not regularized. The regularization term \( E_\alpha(w) \) generally penalizes large weights, thus pushing the weights towards zero, which effectively reduces the complexity of the model. Simply put: Regularization favors simpler models that are less likely to learn noise in the data and generalize better. In case the classifier overfits the data, it is strongly recommended to try different values for the parameter 'weight_prior' to improve the generalization properties.
of the neural network. Choosing its value is a trade-off between the model’s ability to generalize, overfitting, and underfitting. If \( \alpha \) is too small, the model might overfit, if its too large the model might lose its ability to fit the data, because all weights are effectively zero. For finding an ideal value for \( \alpha \), we recommend a cross-validation, i.e., to perform the training for a range of values and choose the value that results in the best validation error. For typical applications, we recommend testing the values for ‘weight_prior’ on a logarithmic scale between \( 1.0,\ldots,0.0001 \). If the training takes a very long time, one might consider performing the hyperparameter optimization on a reduced amount of data. The default value depends on the classifier.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

Attention

To successfully set ‘gpu’ parameters, cuDNN and cuBLAS are required, i.e., to set the parameter `GenParamName runtime’ to ‘gpu’ or to set the `GenParamName 'gpu’. For further details, please refer to the “Installation Guide”, paragraph “Requirements for Deep Learning and Deep-Learning-Based Methods”.

Parameters

- **DLClassifierHandle** (input_control) Handle of the deep-learning-based classifier.
- **GenParamName** (input_control) Name of the generic parameter. Default value: ‘classes’
- **GenParamValue** (input_control) Value of the generic parameter. Suggested values: `GenParamValue ∈ \{1, 2, 3, 50, 0.001, ‘cpu’, ‘gpu’, ‘immediately’\}

Result

If the parameters are valid, the operator `set_dl_classifier_param` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- **read_dl_classifier**

Possible Successors

- **get_dl_classifier_param, apply_dl_classifier, train_dl_classifier_batch**

Alternatives

- **get_dl_classifier_param**

Deep Learning Inference

```c
train_dl_classifier_batch ( BatchImages : : DLClassifierHandle, BatchLabels : DLClassifierTrainResultHandle )
```

Perform a training step of a deep-learning-based classifier on a batch of images.

`train_dl_classifier_batch` is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator `train_dl_model_batch`.
train_dl_classifier_batch performs a training step of the deep-learning-based classifier contained in DLClassifierHandle. The classifier handle DLClassifierHandle has to be read previously using read_dl_classifier. In order to apply training steps, classes have to be specified using set_dl_classifier_param. Other hyperparameters such as the learning rate and the momentum are also important for a successful training. They are set using set_dl_classifier_param.

The training step is done on basis of a single batch of images from the training dataset, thus the images BatchImages with labels BatchLabels. The number of images within the batch needs to be a multiple of the 'batch_size' where the parameter 'batch_size' is limited by the amount of available GPU memory. In order to process more images in one training step, the classifier parameter 'batch_size_multiplier' can be set to a value greater than 1. The number of images being passed to the training operator needs to be equal to 'batch_size' times 'batch_size_multiplier'. Note that a training step calculated for a batch and a 'batch_size_multiplier' greater 1 is an approximation of a training step calculated for the same batch but with a 'batch_size_multiplier' equal to 1 and an accordingly greater 'batch_size'. As an example, the loss calculated with a 'batch_size' of 4 and a 'batch_size_multiplier' of 2 is usually not equal to the loss calculated with a 'batch_size' of 8 and a 'batch_size_multiplier' of 1, although the same number of images is used for training in both cases. However, the approximation generally delivers comparably good results, so it can be utilized if you wish to train with a larger number of images than your GPU allows. In some rare cases the approximation with a 'batch_size' of 1 and an accordingly large 'batch_size_multiplier' does not show the expected performance which for example can happen when the pretrained network 'pretrained_dl_classifier_resnet50.hdl' is used. Setting the 'batch_size' to a value greater than 1 can help to solve this issue.

Note that the images in BatchImages must fulfill certain conditions regarding, for example, the image size and gray value range, depending on the chosen network. Please have a look at read_dl_classifier and set_dl_classifier_param for more information. The labels in BatchLabels can be handed over as an array of strings, or as an array of indices corresponding to the position of the label within the array of classes (counting from 0) set before via 'classes' with set_dl_classifier_param. Information about the results of the training step as the value of the loss are stored in DLClassifierTrainResultHandle and can be accessed using get_dl_classifier_train_result.

Note that an epoch generally consists of a large number of batches and that a successful training involves many epochs. Therefore train_dl_classifier_batch has to be applied several times with different batches. For a more detailed explanation, we refer to Legacy / DL Classification.

During training, a nonlinear optimization algorithm minimizes the value of the loss function. The later one is determined based on the prediction of the neural network on the current batch of images. The algorithm used for optimization is stochastic gradient descent (SGD). It updates the layers’ weights of the previous iteration \( w_t \) to the new values \( w_{t+1} \) at iteration \( t + 1 \) as follows:

\[
\begin{align*}
\mu v^{t+1} &= \mu v^t - \lambda \nabla_w L(f(x, w^t)) \\
\mu v^{t+1} &= \nabla^t + \mu^{t+1}.
\end{align*}
\]

Here, \( \lambda \) is the learning rate, \( \mu \) for the momentum, and \( f(x, w) \) for the classification result of the deep learning-based classifier which depends on the network weights \( w \) and the input batch \( x \). The variable \( v_t \) is used to involve the influence of the momentum \( \mu \). The loss function used here is the Multinomial Logistic Loss in combination with a quadratic regularization term \( E_\alpha(w) \),

\[
L(f(x, w)) = -\frac{1}{N} \sum_{n=0}^{N-1} (y_n, \log(f(x_n, w))) + E_\alpha(w), \quad E_\alpha(w) = \alpha \sum_{k=0}^{K-1} |w_k|^2.
\]

Here, \( y_n \) is a one-hot encoded target vector that encodes the label of the \( n \)-th image \( x_n \) of the batch \( x \) containing \( N \)-many images, and \( \log(f(x_n, w)) \) shall be understood to be a vector such that \( \log_\) is applied on each component of \( f(x_n, w) \). The regularization term \( E_\alpha(w) \) is a weighted \( l^2 \)-norm involving all \( K \) weights except for biases. Its influence can be controlled through \( \alpha \). In the above formula, \( \alpha \) denotes the hyperparameter 'weight_prior' that can be set with set_dl_classifier_param. In order to gain more insight, you can retrieve the current value of the total loss function as well as individual contributions using get_dl_classifier_train_result.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.
Attention

The operator `train_dl_classifier_batch` internally calls functions that might not be deterministic. Therefore, results from multiple calls of `train_dl_classifier_batch` can slightly differ, although the same input values have been used.

To run this operator, cuDNN and cuBLAS are required. For further details, please refer to the “Installation Guide”, paragraph “Requirements for Deep Learning and Deep-Learning-Based Methods”.

Parameters

- **BatchImages** (input_object) 
  (multichannel-)image(-array) → object : real
  Images comprising the batch.

- **DLClassifierHandle** (input_control)
  dl_classifier → handle
  Handle of the deep-learning-based classifier.

- **BatchLabels** (input_control)
  string-array → string / integer
  Corresponding labels for each of the images.
  **Default value:** []
  **List of values:** BatchLabels ∈ {[]}

- **DLClassifierTrainResultHandle** (output_control)
  dl_classifier_train_result → handle
  Handle of the training results from the deep-learning-based classifier.

Result

If the parameters are valid, the operator `train_dl_classifier_batch` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

- read_dl_classifier, set_dl_classifier_param, get_dl_classifier_param
- get_dl_classifier_train_result, apply_dl_classifier, clear_dl_classifier_train_result, clear_dl_classifier

Possible Successors

- train_dl_model_batch, train_class_mlp, train_class_svm

Alternatives

- Deep Learning Training

**write_dl_classifier** ( : : DLClassifierHandle, FileName : )

Write a deep-learning-based classifier in a file.

**write_dl_classifier** is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **write_dl_model** instead.

**write_dl_classifier** writes the deep-learning-based classifier `DLClassifierHandle` to the file given by `FileName`.

**write_dl_classifier** is typically called after the classifier has been trained with `train_dl_classifier_batch`. The classifier can be read with `read_dl_classifier`.

Please note that the runtime specific parameter 'gpu' of the classifier is not written.

The default HALCON file extension for deep learning classifiers is '.hdl'.
For an explanation of the concept of deep-learning-based classification see the introduction of chapter Deep Learning / Classification. The workflow involving this legacy operator is described in the chapter Legacy / DL Classification.

### Parameters

- **DLClassifierHandle** (input_control) .......... dl_classifier ↳ handle
  Handle of the deep-learning-based classifier.
- **FileName** (input_control) .................. filename.write ↳ string
  File name.
  **File extension:** .hdl

### Result

If the parameters are valid, the operator `write_dl_classifier` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### 17.5 Develop

#### `dev_map_par` ( : : : )

Open the dialog to specify the visualization parameters.

`dev_map_par` is obsolete and is only provided for reasons of backward compatibility. New applications should use `dev_open_tool` with `ToolType` set to `'visualization_parameters_dialog'` instead.

`dev_map_par` opens the Visualization Parameter dialog. This can also be achieved interactively via the menu `Visualization` ▹ `Set Parameters...` or the appropriate tool bar button. The dialog is used to configure the visualization parameters that are used to display iconic objects.

This operator is not supported for code export.

#### Example

```halcon
read_image (Image, 'fabrik')
threshold (Image, Region, 128, 255)
dev_map_par ()
```

**Result**

`dev_map_par` returns always 2 (H_MSG_TRUE).

### Possible Successors

- `dev_unmap_par`

### Module

**Foundation**
### dev_map_prog ( : : : )

Make the main window of HDevelop visible.

**dev_map_prog** is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_open_tool** with **ToolType** set to ‘program_window’ instead.

**dev_map_prog** is used to re-show (map) the main window of HDevelop after it has been hidden (unmapped) by **dev_unmap_prog**.

```
dev_map_prog ( : : : )
```

Attention

This operator is not supported for code export.

Depending on the operating system or the window manager the execution of **dev_map_prog** will result only in a visible icon of the window. In this case it has to be opened by the user with mouse interaction.

Result

**dev_map_prog** always returns 2 (H_MSG_TRUE).

Possible Predecessors

**dev_unmap_prog**

Possible Successors

**dev_unmap_prog**

See also

**dev_map_par, dev_map_var**

Module

### dev_map_var ( : : : )

Open the variable window of HDevelop.

**dev_map_var** is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_open_tool** with **ToolType** set to ‘variable_window’ instead.

**dev_map_var** is used to re-show (map) the variable window on the screen after it has been hidden (unmapped) by **dev_unmap_var**.

```
dev_map_var ( : : : )
```

Attention

This operator is not supported for code export.

Result

**dev_map_var** always returns 2 (H_MSG_TRUE).

Possible Predecessors

**dev_unmap_var**

Possible Successors

**dev_unmap_var**

See also

**dev_map_par, dev_map_prog**

Module

### dev_unmap_par ( : : : )

Closes the dialog to specify the visualization parameters.

**dev_unmap_par** is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_close_tool** with **ToolType** set to ‘visualization_parameters_dialog’ instead.
dev_unmap_par closes the Visualization Parameter dialog. This can also be achieved interactively by pressing the Close button on the dialog’s title bar. The dialog can be opened again by dev_map_par.

Attention

This operator is not supported for code export.

Result

dev_unmap_par always returns 2 (H_MSG_TRUE).

Possible Successors

dev_map_par

See also
dev_map_par, dev_map_prog, dev_map_var

Module

Foundation

---

**dev_unmapProg** ( : : : )

Hide the main window.

dev_unmap_prog is obsolete and is only provided for reasons of backward compatibility. New applications should use dev_close_tool with ToolType set to ‘program_window’ instead.

dev_unmap_prog hides in MDI mode the main window and in SDI mode the program window so that it is no longer visible. It can be shown again by dev_map_prog.

Attention: after hiding the main window there is no opportunity to enter and execute the dev_map_prog operator. So take care that dev_unmap_prog is only executed in continuous mode with a reachable dev_map_prog operator.

Attention

This operator is not supported for code export.

Result

dev_unmap_prog always returns 2 (H_MSG_TRUE).

Possible Successors

dev_map_prog, stop

See also
dev_map_par, dev_map_prog, dev_map_var

Module

Foundation

---

**dev_unmapVar** ( : : : )

Hides the variable window.

dev_unmap_var is obsolete and is only provided for reasons of backward compatibility. New applications should use dev_close_tool with ToolType set to ‘variable_window’ instead.

dev_unmap_var hides the variable window. This can also be achieved interactively by pressing the Close button on the window’s title bar. The window can be opened again by dev_map_var or interactively via the Window menu.

Attention

This operator is not supported for code export.

Result

dev_unmap_var always returns 2 (H_MSG_TRUE).

Possible Successors

dev_map_var
17.6 Filters

\texttt{gauss\_image} (Image : ImageGauss : Size :)

\textit{Smooth an image using discrete Gaussian functions.}

\texttt{gauss\_image} is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator \texttt{gauss\_filter} instead.

The operator \texttt{gauss\_image} smooths images using the discrete Gaussian. The smoothing effect increases with increasing filter size. The following filter sizes (\texttt{Size}) are supported (the sigma value of the Gauss function is indicated in brackets):

\begin{itemize}
  \item 3 (0.65)
  \item 5 (0.87)
  \item 7 (1.43)
  \item 9 (1.88)
  \item 11 (2.31)
\end{itemize}

For border treatment the gray values of the images are reflected at the image borders.

The operator \texttt{binomial\_filter} can be used as an alternative to \texttt{gauss\_image}. \texttt{binomial\_filter} is significantly faster than \texttt{gauss\_image}. It should be noted that the mask size in \texttt{binomial\_filter} does not lead to the same amount of smoothing as the mask size in \texttt{gauss\_image}. Corresponding mask sizes can be determined based on the respective values of the Gaussian smoothing parameter sigma.

\texttt{gauss\_image} can be executed on OpenCL devices for all supported image types. However, the OpenCL implementation can produce slightly different results from the scalar implementation.

For an explanation of the concept of smoothing filters see the introduction of chapter \texttt{Filters / Smoothing}.

\textbf{Attention}

In order to be able to process \texttt{gauss\_image} on on OpenCL device, \texttt{Image} must be at least 64 pixels in both width and height.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter \texttt{Filters}.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{Image} (input\_object) \hspace{1cm} (multichannel)-image(-array) \sim object : byte / int2 / uint2 / int4 / real
    Image to be smoothed.
  \item \texttt{ImageGauss} (output\_object) \hspace{1cm} (multichannel)-image(-array) \sim object : byte / int2 / uint2 / int4 / real
    Filtered image.
  \item \texttt{Size} (input\_control) \hspace{1cm} \text{integer} \sim \text{integer}
    Required filter size.
    \textbf{Default value:} 5
    \textbf{List of values:} \texttt{Size} \in \{3, 5, 7, 9, 11\}
\end{itemize}

\textbf{Example}

\texttt{gauss\_image(Input,Gauss,7)}
\texttt{regiongrowing(Gauss,Segments,7,7,5,100)}

\textbf{Complexity}

For each pixel: $O(\text{Size} \times 2)$. 

HALCON/HDevelop Reference Manual, 2020-11-10
17.6. FILTERS

Result

If the parameter values are correct the operator `gauss_image` returns the value 2 (H_MSG_TRUE).
The behavior in case of empty input (no input images available) is set via the operator `set_system` ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

• Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on domain level.

Module

Foundation

```c
polar_trans_image ( ImageXY : ImagePolar : Row, Column, Width,
                    Height : )
```

Transform an image to polar coordinates

`polar_trans_image` is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator `polar_trans_image_ext` instead.

`polar_trans_image` transforms an image in Cartesian coordinates to an image in polar coordinates. The size of the resulting image is selected with `Width` and `Height`. `Width` determines the angular resolution, while `Height` determines the resolution of the radius. `Row` and `Column` determine the center of the polar coordinate system in the original image `ImageXY`. This point is mapped to the upper row of `ImagePolar`.

A point (x',y') in the result image corresponds to the point (x,y) in the original image in the following manner:

\[
x = y' \cdot \cos(2\pi(x'/\text{result_width})) + \text{Column}
\]

\[
y = y' \cdot \sin(2\pi(x'/\text{result_width})) + \text{Row}.
\]

`polar_trans_image` can be executed on an OpenCL device if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- **ImageXY** (input_object) ............................ (multichannel-image-array)  ️ object : byte / int2 / uint2 / real
  Input image in Cartesian coordinates.

- **ImagePolar** (output_object) ...................... (multichannel-image-array)  ️ object : byte / int2 / uint2 / real
  Result image in polar coordinates.

- **Row** (input_control) .............................................................. point.y  ️ integer
  Row coordinate of the center of the coordinate system.

Default value: 100

Suggested values: `Row ∈ {0, 10, 100, 200}`

Typical range of values: `0 ≤ Row ≤ 512`

Minimum increment: 1

Recommended increment: 1

HALCON 20.11.0.0
Column (input_control) ................................................................. point.x ~ integer

Column coordinate of the center of the coordinate system.

Default value: 100
Suggested values: Column ∈ {0, 10, 100, 200}
Typical range of values: 0 ≤ Column ≤ 512
Minimum increment: 1
Recommended increment: 1

Width (input_control) ................................................................. extent.x ~ integer

Width of the result image.

Default value: 314
Suggested values: Width ∈ {100, 200, 157, 314, 512}
Typical range of values: 2 ≤ Width ≤ 512
Minimum increment: 1
Recommended increment: 10

Height (input_control) ............................................................... extent.y ~ integer

Height of the result image.

Default value: 200
Suggested values: Height ∈ {100, 128, 256, 512}
Typical range of values: 2 ≤ Height ≤ 512
Minimum increment: 1
Recommended increment: 10

Example

read_image(Image,'monkey')
dev_display (Image)
polar_trans_image(Image,PolarImage,100,100,314,200)
dev_display (PolarImage)

Execution Information

• Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.

Module

17.7 Graphics

clear_rectangle ( : : WindowHandle, Row1, Column1, Row2, Column2 : )

Delete a rectangle on the output window.

clear_rectangle is obsolete and is only provided for reasons of backward compatibility.

clear_rectangle deletes all entries in the rectangle which is defined through the upper left corner (Row1,Column1) and the lower right corner (Row2,Column2). Deletion means that the specified rectangle is set to the background color (see open_window).

If you want to delete more than one rectangle, you may pass several rectangles, i.e., the parameters Row1, Column1, Row2 and Column2 are tuples.
17.7. GRAPHICS

Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Row1** (input_control)  
  Line index of upper left corner.
  Default value: 10
  Typical range of values: \(0 \leq \text{Row1} \leq 511\) (lin)
  Minimum increment: 1
  Recommended increment: 1

- **Column1** (input_control)  
  Column index of upper left corner.
  Default value: 10
  Typical range of values: \(0 \leq \text{Column1} \leq 511\) (lin)
  Minimum increment: 1
  Recommended increment: 1

- **Row2** (input_control)  
  Row index of lower right corner.
  Default value: 118
  Typical range of values: \(0 \leq \text{Row2} \leq 511\) (lin)
  Minimum increment: 1
  Recommended increment: 1
  Restriction: \(\text{Row2} > \text{Row1}\)

- **Column2** (input_control)  
  Column index of lower right corner.
  Default value: 118
  Typical range of values: \(0 \leq \text{Column2} \leq 511\) (lin)
  Minimum increment: 1
  Recommended increment: 1
  Restriction: \(\text{Column2} \geq \text{Column1}\)

Example

* Erase a rectangle in the output window interactively:
  draw_rectangle1(WindowHandle,L1,C1,L2,C2)

Result

If an output window exists and the specified parameters are correct, `clear_rectangle` returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- `open_window`, `set_draw`, `set_color`, `set_colored`, `set_line_width`, `set_rgb`, `set_hsi`, `draw_rectangle1`

Alternatives

- `clear_window`, `disp_rectangle1`

See also

- `open_window`

Module

Foundation
disp_distribution ( : : WindowHandle, Distribution, Row, Column, Scale : )

Displays a noise distribution.

disp_distribution is obsolete and is only provided for reasons of backward compatibility.

disp_distribution displays a distribution in the window. Row and Column define the position of the center of the graphic. Scale allows scaling of the graphic, whereby 1 means displaying all 256 values, 2 means displaying 128 values, 3 means displaying only 64 values, etc. Noise distributions can be generated with operations like gauss_distribution or noise_distribution_mean.

Parameters

- **WindowHandle** (input_control) Window handle.
- **Distribution** (input_control) Gray value distribution (513 values).
- **Row** (input_control) Row index of center.
  - Default value: 256
  - Suggested values: Row ∈ {0, 64, 128, 256}
  - Typical range of values: 0 ≤ Row ≤ 511 (lin)
  - Minimum increment: 1
  - Recommended increment: 10
- **Column** (input_control) Column index of center.
  - Default value: 256
  - Suggested values: Column ∈ {0, 64, 128, 256}
  - Typical range of values: 0 ≤ Column ≤ 511 (lin)
  - Minimum increment: 1
  - Recommended increment: 10
- **Scale** (input_control) Size of display.
  - Default value: 1
  - Suggested values: Scale ∈ {1, 2, 3, 4, 5, 6}

Example

open_window(0,0,-1,-1,'root', 'visible', '',WindowHandle)
set_draw(WindowHandle, 'fill')
set_color(WindowHandle, 'white')
read_image(Image, 'monkey')
draw_region(Region, WindowHandle)
noise_distribution_mean(Region, Image, 21, Distribution)
disp_distribution (WindowHandle, Distribution, 100, 100, 3)

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_draw, set_color, set_colored, set_line_width, set_rgb, set_hsi, noise_distribution_mean, gauss_distribution

See also

gen_region_histo, gauss_distribution, noise_distribution_mean

Module

Foundation
**disp_lut** ( : : WindowHandle, Row, Column, Scale : )

*Graphical view of the look-up-table (lut).*

`disp_lut` is obsolete and is only provided for reasons of backward compatibility.

`disp_lut` displays a graphical view of the look-up-table (lut) in the valid window. A look-up-table defines the transformation of image gray values to colors/gray levels on the screen. On most systems this can be modified. `disp_lut` creates a graphical view of the table assigned to the output window with the logical window number `WindowHandle` and displays it for every basic color (red, green, blue). `Row` and `Column` define the position of the center of the graphic. `Scale` allows scaling of the graphic, whereby 1 means displaying all 256 values, 2 means displaying 128 values, 3 means displaying only 64 values, etc. Tables for monochrome-representations are displayed in the currently set color (see `set_color`, `set_rgb`, etc.). Tables for displaying “false colors” are viewed with red, green and blue for each color component.

- **Parameters**
  - `WindowHandle` (input_control) : window ~ handle
    Window handle.
  - `Row` (input_control) : point.y ~ integer
    Row of center of the graphic.
    Default value: 128
    Typical range of values: 0 ≤ Row ≤ 511
  - `Column` (input_control) : point.x ~ integer
    Column of center of the graphic.
    Default value: 128
    Typical range of values: 0 ≤ Column ≤ 511
  - `Scale` (input_control) : integer ~ integer
    Scaling of the graphic.
    Default value: 1
    List of values: Scale ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
    Typical range of values: 0 ≤ Scale ≤ 20

- **Result**
  `disp_lut` returns 2 (H_MSG_TRUE) if the hardware supports a look-up-table, the window is valid and the parameters are correct. Otherwise an exception is raised.

- **Execution Information**
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

- **Possible Predecessors**
  - `set_lut`

- **See also**
  - `open_window`, `set_lut`, `set_fix`, `set_pixel`, `write_lut`, `get_lut`, `set_color`

- **Module**
  - Foundation

**get_comprise** ( : : WindowHandle : Mode )

*Get the output treatment of an image matrix.*

`get_comprise` is obsolete and is only provided for reasons of backward compatibility.

`get_comprise` returns the output mode of gray values in the window `WindowHandle` that is used by `disp_image` and `disp_color`. The output mode defines whether only the gray values of objects are displayed or the whole image is displayed. The query is used for temporary mode settings, i.e., the current mode is queried, then overwritten with (`set_comprise`) and finally reset.
get_comprise returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_comprise, disp_image, disp_image

See also

set_comprise, disp_image, disp_color

Module

get_fix ( : : WindowHandle : Mode )

Get mode of fixing of current look-up-table (lut).

get_fix is obsolete and is only provided for reasons of backward compatibility.

Use get_fix to get mode of fixing of current look-up-table (look-up-table of valid window) set before by set_fix.

Parameters

- WindowHandle (input_control) window handle.
- Mode (output_control) Display mode for images.

Result

get_fix returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_fix, set_pixel, set_rgb

See also

set_fix

Module

get_fixed_lut ( : : WindowHandle : Mode )

Get fixing of “look-up-table” (lut) for “real color images”
get_fixed_lut is obsolete and is only provided for reasons of backward compatibility.

Get fixing of “look-up-table” (lut) for “real color images”

Parameters

- WindowHandle (input_control) \(\leadsto handle\) Window handle.
- Mode (output_control) \(\leadsto string\) Mode of fixing.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_fixed_lut

Module

Foundation

get_insert ( : : WindowHandle : : Mode )

Get the current display mode.

get_insert is obsolete and is only provided for reasons of backward compatibility.

get_insert returns the display mode of the output window. It is used by operators like disp_region, disp_line, disp_rectangle1, etc. The mode is set with set_insert. Possible values for Mode can be queried with the operator query_insert.

Parameters

- WindowHandle (input_control) \(\leadsto handle\) Window handle.
- Mode (output_control) \(\leadsto string\) Display mode.

Result

get_insert returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

query_insert

Possible Successors

set_insert, disp_image

See also

set_insert, query_insert, disp_region, disp_line

Module

Foundation

get_line_approx ( : : WindowHandle : : Approximation )

Get the current approximation error for contour display.
**get_line_approx** is obsolete and is only provided for reasons of backward compatibility.

**get_line_approx** returns a parameter that controls the approximation error for region contour display in the window. It is used by the operator disp_region. **Approximation** controls the polygon approximation for contour display (0 ⇔ no approximation). **Approximation** is only important for displaying the contour of objects, especially if a line style was set with **set_line_style**.

```plaintext
Parameters

▷ **WindowHandle** (input_control) ... window ~ handle
   Window handle.

▷ **Approximation** (output_control) ... string ~ integer
   Current approximation error for contour display.
```

**Result**

**get_line_approx** returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Successors**

```
set_line_approx, set_line_style, disp_region
```

**See also**

```
get_region_polygon, set_line_approx, set_line_style, disp_region
```

**Module**

Foundation

---

**get_lut_style** (: : WindowHandle : Hue, Saturation, Intensity )

Get modification parameters of look-up-table (lut).

**get_lut_style** is obsolete and is only provided for reasons of backward compatibility.

**get_lut_style** returns the values that were set with **set_lut_style**. Default is:

- **Hue**: 0.0
- **Saturation**: 1.0
- **Intensity**: 1.0

```plaintext
Parameters

▷ **WindowHandle** (input_control) ... window ~ handle
   Window handle.

▷ **Hue** (output_control) ... real ~ real
   Modification of color value.

▷ **Saturation** (output_control) ... real ~ real
   Modification of saturation.

▷ **Intensity** (output_control) ... real ~ real
   Modification of intensity.
```

**Result**

**get_lut_style** returns 2 (H_MSG_TRUE) if the window is valid and the parameter is correct. Otherwise an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors:

| set_lut_style, set_lut | set_lut_style |

See also:

Module:

get_pixel ( : : WindowHandle : Pixel )

Get the current color lookup table index.

get_pixel is obsolete and is only provided for reasons of backward compatibility.

get_pixel returns the internal coding of the output gray value or color, respectively, for the window. If the output mode is set to color(s) or gray value(s) (see set_color or set_gray), then the color- or gray values are transformed for internal use. The internal code is then used for (physical) screen display. The transformation depends on the mapping characteristics and the condition of the output device and can be different in different program runs. Don’t confuse the term “pixel” with the term “pixel” in image processing (the other operator is get_grayval). Here a pixel is meant to be the color lookup table index.

With get_pixel it is possible to save the output mode without knowing whether colors or gray values are used. Pixel is set with the operator set_pixel.

Parameters:

| WindowHandle | Window handle. |
| Pixel | Index of the current color look-up table. |

Result:

get_part_style returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information:

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors:

| set_pixel, disp_region, disp_image | set_pixel |

See also:

Module:

get_tshape ( : : WindowHandle : TextCursor )

Get the shape of the text cursor.

get_tshape is obsolete and is only provided for reasons of backward compatibility.

get_tshape queries the shape of the text cursor for the output window. A new cursor shape is set by the operator set_tshape.
A text cursor marks the current position for text output (which can also be invisible). It is different from the mouse cursor (although both will be called "cursor" if the context makes misconceptions impossible). The available shapes for the text cursor can be queried with `query_tshape`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>WindowHandle</code> (input_control)</td>
</tr>
<tr>
<td><code>TextCursor</code> (output_control)</td>
</tr>
</tbody>
</table>

`get_tshape` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**
- `open_window`, `set_font`

**Possible Successors**
- `set_tshape`, `set_tposition`, `write_string`, `read_string`, `read_char`

**See also**
- `set_tshape`, `query_tshape`, `write_string`, `read_string`

**Module**
- Foundation

### `gnuplot_close` (: : GnuplotFileID : )

Close all open gnuplot files or terminate an active gnuplot subprocess.

`gnuplot_close` is obsolete and is only provided for reasons of backward compatibility.

`gnuplot_close` closes all gnuplot files opened by `gnuplot_open_file` or terminates the gnuplot subprocess created with `gnuplot_open_pipe`. In the latter case, all temporary files used to display images and control values are deleted. This means that `gnuplot_close` must be called after such a plot sequence. `GnuplotFileID` is the identifier of the corresponding gnuplot output stream.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>GnuplotFileID</code> (input_control)</td>
</tr>
</tbody>
</table>

`gnuplot_close` returns 2 (H_MSG_TRUE) if `GnuplotFileID` is a valid gnuplot output stream. Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**
- `gnuplot_open_pipe`, `gnuplot_open_file`, `gnuplot_plot_image`

**See also**
- `gnuplot_open_pipe`, `gnuplot_open_file`, `gnuplot_plot_image`

**Module**
- Foundation
17.7. GRAPHICS

```
[72x795]1557
gnuplot_open_file ( : : FileName : GnuplotFileID )
```

Open a gnuplot file for visualization of images and control values.

**gnuplot_open_file** is obsolete and is only provided for reasons of backward compatibility.

gnuplot_open_file allows the output of images and control values in a format which can be later processed by gnuplot. The parameter **FileName** determines the base-name of the files to be created by calls to **gnuplot_plot_image**. gnuplot_open_file generates a gnuplot control file with the name `<FileName>.gp`, in which the respective plot commands are written. Each image plotted by **gnuplot_plot_image** (or control values plotted by **gnuplot_plot_ctrl**) creates a data file with the name `<FileName>.dat.<Number>`, where Number is the number of the plot in the current sequence. The generated control file can later be edited to create the desired effect. After the last plot **gnuplot_close** has to be called in order to close all open files. The corresponding identifier for the gnuplot output stream is returned in GnuplotFileID.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>FileName</strong></td>
<td>input_control</td>
<td>Base name for control and data files.</td>
</tr>
<tr>
<td><strong>File extension</strong></td>
<td>.gp</td>
<td></td>
</tr>
<tr>
<td><strong>GnuplotFileID</strong></td>
<td>output_control</td>
<td>Identifier for the gnuplot output stream.</td>
</tr>
</tbody>
</table>

**Result**

**gnuplot_open_file** returns the value 2 (H_MSG_TRUE) if the control file could be opened. Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Successors**

**gnuplot_plot_image**, **gnuplot_close**

**Alternatives**

**gnuplot_open_pipe**

**See also**

**gnuplot_open_pipe**, **gnuplot_close**, **gnuplot_plot_image**

**Module**

Foundation

```
[72x795]1557
gnuplot_open_pipe ( : : : GnuplotFileID )
```

Open a pipe to a gnuplot process for visualization of images and control values.

**gnuplot_open_pipe** is obsolete and is only provided for reasons of backward compatibility.

gnuplot_open_pipe opens a pipe to a gnuplot sub-process with which subsequently images can be visualized as 3D-plots (**gnuplot_plot_image**) or control values can be visualized as 2D-plots (**gnuplot_plot_ctrl**). The sub-process must be terminated after displaying the last plot by calling **gnuplot_close**. The corresponding identifier for the gnuplot output stream is returned in GnuplotFileID.

**Attention**

**gnuplot_open_pipe** is only implemented for Unix-like systems because gnuplot for Windows (**wgnuplot**) cannot be controlled by an external process.
Parameters

- **GnuplotFileID (output_control)**: Identifier for the gnuplot output stream.

Result
gnuplot_open_pipe returns the value 2 (H_MSG_TRUE) if the sub-process could be created. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors
gnuplot_plot_image, gnuplot_plot_ctrl, gnuplot_close

Alternatives
gnuplot_open_file

Module

**gnuplot_plot_ctrl** (: : GnuplotFileID, Values : )

Plot control values using gnuplot.

**gnuplot_plot_ctrl** is obsolete and is only provided for reasons of backward compatibility.

gnuplot_plot_ctrl displays a tuple of control values using gnuplot. If there is an active gnuplot sub-process (started with **gnuplot_open_pipe**), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by **GnuplotFileID**.

Parameters

- **GnuplotFileID (input_control)**: Identifier for the gnuplot output stream.
- **Values (input_control)**: Control values to be plotted (y-values).

Result
gnuplot_plot_ctrl returns the value if **GnuplotFileID** is a valid gnuplot output stream, if the data file for the current plot could be opened, and if only integer or floating point values were passed. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
gnuplot_open_pipe, gnuplot_open_file

Possible Successors
gnuplot_close

See also
gnuplot_open_pipe, gnuplot_open_file, gnuplot_close

Module

Foundation
**gnuplot_plot_funct_1d** ( : : GnuplotFileID, Function : )

Plot a function using gnuplot.

**gnuplot_plot_funct_1d** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_plot_ctrl** displays a function of control values using gnuplot. If there is an active gnuplot subprocess (started with **gnuplot_open_pipe**), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by **GnuplotFileID**.

**Parameters**

- **GnuplotFileID** (input_control) ... handle Identifier for the gnuplot output stream.
- **Function** (input_control) ... function_1d ~ real / integer Function to be plotted.

**Result**

**gnuplot_plot_ctrl** returns 2 (H_MSG_TRUE) if **GnuplotFileID** is a valid gnuplot output stream, and if the data file for the current plot could be opened. Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**gnuplot_open_pipe, gnuplot_open_file**

**Possible Predecessors**

**gnuplot_close**

**Possible Successors**

**Alternatives**

**See also**

**gnuplot_open_pipe, gnuplot_open_file, gnuplot_close**

**Module**

**gnuplot_plot_image** ( Image : : GnuplotFileID, SamplesX, SamplesY, ViewRotX, ViewRotZ, Hidden3D : )

Visualize images using gnuplot.

**gnuplot_plot_image** is obsolete and is only provided for reasons of backward compatibility.

**gnuplot_plot_image** displays an image as a 3D-plot using gnuplot. If there is an active gnuplot sub-process (started with **gnuplot_open_pipe**), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by **GnuplotFileID**. The parameters **SamplesX** and **SamplesY** determine the number of data points in the x- and y-direction, respectively, which gnuplot should use to display the image. They are the equivalent of the gnuplot variables samples and isosamples. The parameters **ViewRotX** and **ViewRotZ** determine the rotation of the plot with respect to the viewer. **ViewRotX** is the rotation of the coordinate system about the x-axis, while **ViewRotZ** is the rotation of the plot about the z-axis. These two parameters correspond directly to the first two parameters of the 'set view' command in gnuplot. The parameter **Hidden3D** determines whether hidden surfaces should be removed. This is equivalent to the 'set hidden3d' command in gnuplot. If a single image is passed to the operator, it is displayed in a separate plot. If multiple images are passed, they are displayed in the same plot.
### Parameters

- **Image** (input_object) 
  - `singlechannelimage` 
  - `object`: `byte / direction / cyclic / int1 / int2 / uint2 / int4 / real` 
  - Image to be plotted.

- **GnuplotFileID** (input_control)
  - `gnuplot` 
  - `handle` 
  - Identifier for the gnuplot output stream.

- **SamplesX** (input_control)
  - `integer` 
  - Number of samples in the x-direction.
  - **Default value:** 64
  - **Typical range of values:** $2 \leq \text{SamplesX} \leq 10000$
  - **Restriction:** `SamplesX >= 2`

- **SamplesY** (input_control)
  - `integer` 
  - Number of samples in the y-direction.
  - **Default value:** 64
  - **Typical range of values:** $2 \leq \text{SamplesY} \leq 10000$
  - **Restriction:** `SamplesY >= 2`

- **ViewRotX** (input_control)
  - `number` 
  - Rotation of the plot about the x-axis.
  - **Default value:** 60
  - **Typical range of values:** $0 \leq \text{ViewRotX} \leq 180$
  - **Minimum increment:** 0.01
  - **Recommended increment:** 10
  - **Restriction:** $0 \leq \text{ViewRotX} \leq 180$

- **ViewRotZ** (input_control)
  - `number` 
  - Rotation of the plot about the z-axis.
  - **Default value:** 30
  - **Typical range of values:** $0 \leq \text{ViewRotZ} \leq 360$
  - **Minimum increment:** 0.01
  - **Recommended increment:** 10
  - **Restriction:** $0 \leq \text{ViewRotZ} \leq 360$

- **Hidden3D** (input_control)
  - `string` 
  - Plot the image with hidden surfaces removed.
  - **Default value:** `'hidden3d'`
  - **List of values:** `Hidden3D \in \{'hidden3d', 'nohidden3d'\}`

### Result

`gnuplot_plot_image` returns the value if `GnuplotFileID` is a valid gnuplot output stream, and if the data file for the current plot could be opened. Otherwise, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `gnuplot_open_pipe, gnuplot_open_file`

### Possible Successors

- `gnuplot_close`

See also

- `gnuplot_open_pipe, gnuplot_open_file, gnuplot_close`

Module

Foundation
move_rectangle  ( : : WindowHandle, Row1, Column1, Row2, Column2, DestRow, DestColumn : )

Copy inside an output window.

move_rectangle is obsolete and is only provided for reasons of backward compatibility.

move_rectangle copies all entries in the rectangle (Row1,Column1), (Row2,Column2) of the output window to a new position inside the same window. This position is determined by the upper left corner (DestRow, DestColumn). Regions of the window, which are “uncovered” through moving the rectangle, are set to the color of the background.

If you want to move several rectangles at once, you may pass parameters in form of tuples.
Result
If the window is valid and the specified parameters are correct, \texttt{move_rectangle} returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

\texttt{open_window}

Alternatives

\texttt{copy_rectangle}

See also

\texttt{open_window}

Module

\textbf{Foundation}

\begin{verbatim}
open_textwindow ( : : Row, Column, Width, Height, BorderWidth,
             BorderColor, BackgroundColor, FatherWindow, Mode,
             Machine : WindowHandle )
\end{verbatim}

Open a textual window.

\texttt{open_textwindow} is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator \texttt{open_window} instead.

\texttt{open_textwindow} opens a new textual window, which can be used to perform textual input and output, as well as to perform output of images. All output (\texttt{write_string}, \texttt{read_string}, \texttt{disp_region}, etc.) is redirected to this window, if the same logical window number \texttt{WindowHandle} is used.

Besides the mouse cursor textual windows possess also a textual cursor which indicates the current writing position (more exactly: the lower left corner of the output string without consideration of descenders). Its position is indicated through an underscore or another type (the indication of this position may also be disabled (= default setting); cf. \texttt{set_tshape}). You may set or query the position by calling the operators \texttt{set_tposition} or \texttt{get_tposition}.

After you opened a textual window the position of the cursor is set to (H,0). Whereby H signifies the height of the default font less the descenders. But the cursor is not shown. Hence the output starts for writing in the upper left corner of the window.

You may query the colors of the background and the image edges by calling \texttt{query_color}. In the same way you may use \texttt{query_color} in a window of type ‘invisible’. During output (\texttt{write_string}) you may set the clipping of text out of the window edges by calling \texttt{set_check(‘~text’)}). This disables the creation of error messages, if text passes over the edge of the window.

The origin of the coordinate system of the window resides in the upper left corner (coordinates: (0,0)). The row index grows downward (maximal: \texttt{Height}-1), the column index grows to the right (maximal: \texttt{Width}-1).

The parameter \texttt{Machine} indicates the name of the computer, which has to open the window. In case of a X-window, TCP-IP only sets the name, DEC-Net sets in addition a colon behind the name. The “server” or the “screen”, respectively, are not specified. If the empty string is passed the environment variable DISPLAY is used. It indicates the target computer. At this the name is indicated in common syntax

\begin{verbatim}
<Host>:0.0
\end{verbatim}

For windows of type ‘WIN32-Window’, ‘X-Window’, and ‘Cocoa’ the parameter \texttt{FatherWindow} can be used to determine the father window for the window to be opened. In case the control ‘father’ is set via \texttt{set_check}, \texttt{FatherWindow} must be the ID of a HALCON window, otherwise (\texttt{set_check(‘~father’)}) it can also be the
ID of an operating system window. If FatherWindow is passed the value 0 or 'root', then under Windows and Unix-like systems the desktop and the root window become the father window, respectively. In this case, the value of the control 'father' (set via set_check) is irrelevant. The caller must ensure that FatherWindow is a valid handle and not destroyed as long as the embedded HALCON window is used.

Position and size of a window may change during runtime of a program. This may be achieved by calling set_window_extents, but also through external interferences (window manager). In the latter case the operator set_window_extents is provided.

Opening a window causes the assignment of a called default font. It is used in connection with operators like write_string and you may overwrite it by performing set_font after calling open_textwindow. On the other hand you have the possibility to specify a default font by calling set_system(:: 'default_font', <Fontname>::) before opening a window (and all following windows; see also query_font).

You may set the color of the font (write_string, read_string) by calling set_color, set_rgb, set_hsi or set_gray. Calling set_insert specifies how the text or the graphics, respectively, is combined with the content of the image repeat memory. So you may achieve by calling, e.g., set_insert(;'not':) to eliminate the font after writing text twice at the same position.

Normally every output (e.g., write_string, disp_region, disp_circle, etc.) in a window is terminated by a “flush”. This causes the data to be fully visible on the display after termination of the output operator. But this is not necessary in all cases, in particular if there are permanently output tasks or there is a mouse procedure active. Therefore it is more favorable (i.e., more rapid) to store the data until sufficient data is available. You may stop this behavior by calling set_system(;'flush_graphic', 'false':).

The content of windows is saved (in case it is supported by special driver software); i.e., it is preserved, also if the window is hidden by other windows. But this is not necessary in all cases: If you use a textual window, e.g., as a parent window for other windows, you may suppress the security mechanism for it and save the necessary memory at the same moment. You achieve this before opening the window by calling set_system(;'backing_store', 'false':).

Difference: graphical window - textual window

- In contrast to graphical windows (open_window) you may specify more parameters (color, edge) for a textual window while opening it.
- You may use textual windows only for input of user data (read_string).
- Using textual windows, the output of images, regions and graphics is “clipped” at the edges. Whereas during the use of graphical windows the edges are “zoomed”.
- The coordinate system (e.g., with get_mbutton or get_mposition) consists of display coordinates independently of image size. The maximum coordinates are equal to the size of the window minus 1. In contrast to this, graphical windows (open_window) use always a coordinate system, which corresponds to the image format.

The parameter Mode specifies the mode of the window. It can have following values:

'visible': Normal mode for textual windows: The window is created according to the parameters and all inputs and outputs are possible.

'invisible': Invisible windows are not displayed in the display. Parameters like Row, Column, BorderWidth, BorderColor, BackgroundColor and FatherWindow do not have any meaning. Output to these windows has no effect. Input (read_string, mouse, etc.) is not possible. You may use these windows to query representation parameter for an output device without opening a (visible) window. General queries are, e.g., query_color and get_string_extents.

'transparent': These windows are transparent: the window itself is not visible (edge and background), but all the other operations are possible and all output is displayed. Parameters like BorderColor and BackgroundColor do not have any meaning. A common use for this mode is the creation of mouse sensitive regions.

'buffer': These are also not visible windows. The output of images, regions and graphics is not visible on the display, but is stored in memory. Parameters like Row, Column, BorderWidth, BorderColor, BackgroundColor and FatherWindow do not have any meaning. You may use buffer windows, if you prepare output (in the background) and copy it finally with copy_rectangle in a visible window. Another usage might be the rapid processing of image regions during interactive manipulations. Textual input and mouse interaction are not possible in this mode.

HALCON 20.11.0.0
You have to keep in mind that parameters like Row, Column, Width and Height are restricted by the output device. Is a father window (FatherWindow <> 'root') specified, then the coordinates are relative to this window.

### Parameters

#### Row (input_control)
- **Description**: Row index of upper left corner.
- **Default value**: 0
- **Typical range of values**: $0 \leq \text{Row (lin)}$
- **Minimum increment**: 1
- **Recommended increment**: 1
- **Restriction**: \( \text{Row} \geq 0 \)

#### Column (input_control)
- **Description**: Column index of upper left corner.
- **Default value**: 0
- **Typical range of values**: $0 \leq \text{Column (lin)}$
- **Minimum increment**: 1
- **Recommended increment**: 1
- **Restriction**: \( \text{Column} \geq 0 \)

#### Width (input_control)
- **Description**: Window’s width.
- **Default value**: 256
- **Typical range of values**: $0 \leq \text{Width (lin)}$
- **Minimum increment**: 1
- **Recommended increment**: 1
- **Restriction**: \( \text{Width} > 0 \)

#### Height (input_control)
- **Description**: Window’s height.
- **Default value**: 256
- **Typical range of values**: $0 \leq \text{Height (lin)}$
- **Minimum increment**: 1
- **Recommended increment**: 1
- **Restriction**: \( \text{Height} > 0 \)

#### BorderWidth (input_control)
- **Description**: Window border’s width.
- **Default value**: 2
- **Typical range of values**: $0 \leq \text{BorderWidth (lin)}$
- **Minimum increment**: 1
- **Recommended increment**: 1
- **Restriction**: \( \text{BorderWidth} \geq 0 \)

#### BorderColor (input_control)
- **Description**: Window border’s color.
- **Default value**: ’white’

#### BackgroundColor (input_control)
- **Description**: Background color.
- **Default value**: ’black’

#### FatherWindow (input_control)
- **Description**: Logical number of the father window. For the display as father you may specify ’root’ or 0.
- **Default value**: 0
- **Restriction**: \( \text{FatherWindow} \geq 0 \)

#### Mode (input_control)
- **Description**: Window mode.
- **Default value**: ’visible’
- **List of values**: \( \text{Mode} \in \{’visible’, ’invisible’, ’transparent’, ’buffer’\} \)

#### Machine (input_control)
- **Description**: Computer name, where the window has to be opened or empty string.
- **Default value**: ”
WindowHandle (output_control)  

Window handle.

--- Example ---

open_textwindow(0,0,900,600,1,'black','slate blue','root','visible', 

'','WindowHandle1)
open_textwindow(10,10,300,580,3,'red','blue',WindowHandle1,'visible', 

'','WindowHandle2)
open_window(10,320,570,580,WindowHandle1,'visible','',WindowHandle)
set_color(WindowHandle1,'red')
read_image(Image,'monkey')
disp_image(Image,WindowHandle)
Button := 0
repeat
  try
    get_mposition(WindowHandle,Row,Column,Button)
    get_grayval(Image,Row,Column,Gray)
    write_string(WindowHandle2,[' Position (',Row,',',Column,') '])
    write_string(WindowHandle2,['Gray value (',Gray,') '])
    new_line(WindowHandle2)
  catch (Exception)
    endtry
until(Button == 4)
close_window(WindowHandle1)

--- Result ---

If the values of the specified parameters are correct open_textwindow returns 2 (H_MSG_TRUE). If necessary an exception is raised.

--- Execution Information ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

--- Module ---

query_insert ( : : WindowHandle : Mode )

Query the possible graphic modes.
query_insert is obsolete and is only provided for reasons of backward compatibility.

query_insert returns the possible modes pixels can be displayed in the output window. New pixels may e.g. overwrite old ones. In most of the cases there is a functional relationship between old and new values.

Possible display functions:

'copy': overwrite displayed pixels
'xor': display old “xor” new pixels
'complement': complement displayed pixels

“copy” is always available.

Parameters

WindowHandle (input_control) window ~ handle
Window handle.

Mode (output_control) string-array ~ string
Display function name.

Result

query_insert returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

HALCON/HDevelop Reference Manual, 2020-11-10

query_tshape ( : : WindowHandle : : TextCursor )

Query all shapes available for text cursors.

query_tshape is obsolete and is only provided for reasons of backward compatibility.

query_tshape queries the available shapes of text cursors for the output window. The retrieved shapes can be used by the operator set_tshape.

Parameters

WindowHandle (input_control) window ~ handle
Window handle.

TextCursor (output_control) string-array ~ string
Names of the available text cursors.

Result

query_tshape returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
set_comprise ( : : WindowHandle, Mode : )

Define the image matrix output clipping.

set_comprise is obsolete and is only provided for reasons of backward compatibility.

set_comprise defines the image matrix output clipping. If Mode is set to 'object', only gray values belonging to the output object are displayed. If set to 'image', the whole image matrix is displayed. Default is 'object'.

Attention
If Mode was set to 'image', undefined gray values may be displayed. Depending on the context they are black or can have random content. See the examples.

Parameters

▷ WindowHandle (input_control) \( \leadsto \) window  
Window handle.

▷ Mode (input_control) \( \leadsto \) string  
Clipping mode for gray value output.  
Default value: 'object'  
List of values: Mode \( \in \{ \text{'image'}, \text{'object'} \} \)

Example

read_image(Image,'fabrik')  
gen_circle (Circle, 200, 200, 100.5)  
reduce_domain (Image, Circle, ImageReduced)  
set_system('init_new_image','false')  
sobel_amp(ImageReduced,SobelReduced,'sum_abs',3)  
dev_display (SobelReduced)  
get_comprise(WindowHandle,Mode)  
set_comprise(WindowHandle,'image')  
stop ()  
dev_display (SobelReduced)

Result

set_comprise returns 2 (H_MSG_TRUE) if Mode is correct and the window is valid. Otherwise an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors
get_comprise

Possible Successors
disp_image
set_fix ( : : WindowHandle, Mode : )

Set fixing of “look-up-table” (lut)

set_fix is obsolete and is only provided for reasons of backward compatibility.

Behaviour for Mode = ’true’: set_fix fixes that pixel lastly ascertained by one of the operators set_gray, set_color, set_hsi or set_rgb (Remark: Here a pixel is the index within the current look-up-table). To assign a new color to a fixed pixel set a color or gray value by using set_color, set_rgb, set_hsi or set_gray. This makes it possible to define any color (set_color), any gray value (set_gray) and any color combination (set_rgb, set_hsi) at any position of the look-up-table.

Mode set to ’false’ reset the fixing. To modify or create a look-up-table process set_pixel, set_fix(::WindowHandle,’true’), set_rgb and set_fix(::WindowHandle,’false’) one after another.

Attention

As a side effect set_fix can change colors of “non-HALCON windows”.

Parameters

- WindowHandle (input_control) Specifies the window handle.
- Mode (input_control) Specifies the mode of fixing. Default value: ’true’ List of values: Mode ∈ {’true’, ’false’}

Result

set_fix returns 2 (H_MSG_TRUE) if the window is valid, the hardware supports a look-up-table and all parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Foundation

set_fixed_lut ( : : WindowHandle, Mode : )

Fix “look-up-table” (lut) for “real color images”.

set_fixed_lut is obsolete and is only provided for reasons of backward compatibility.

Fix “look-up-table” (lut) for “real color images”.

HALCON/HDevelop Reference Manual, 2020-11-10
### Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Mode** (input_control)  
  Mode of fixing.
  
  **Default value:** 'true'
  
  **List of values:** Mode ∈ {'true', 'false'}

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `get_fixed_lut`

### Module

**Foundation**

```c
set_insert ( : : WindowHandle, Mode : )
```

**set_insert** is obsolete and is only provided for reasons of backward compatibility.

**set_insert** defines the function, with which pixels are displayed in the output window. It is e.g. possible for a pixel to overwrite the old value. In most of the cases there is a functional relationship between old and new values. The definition value is only valid for the valid window. Output operators that honor **Mode** are e.g. `disp_region`, `disp_polygon`, `disp_circle`.

Possible display functions are:

- **'copy'**: overwrite displayed pixels
- **'xor'**: display old "xor" new pixels
- **'complement'**: complement displayed pixels

There may not be all functions available, depending on the physical display. However, "copy" is always available.

### Parameters

- **WindowHandle** (input_control)  
  Window handle.

- **Mode** (input_control)  
  Name of the display function.
  
  **Default value:** 'copy'
  
  **List of values:** Mode ∈ {'copy', 'xor', 'complement'}

### Result

**set_insert** returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
**set_line_approx** ( : : WindowHandle, Approximation : : )

**Define the approximation error for contour display.**

*set_line_approx* is obsolete and is only provided for reasons of backward compatibility.

*set_line_approx* defines the approximation error for region and xld contour display in the window WindowHandle. Approximation values greater than zero cause an approximation of line strokes using less points. This may enable faster and in some cases smoother visualization. The parameter describes the maximal deviation in pixels of the approximated contour from the original contour (Ramer-Douglas-Peucker algorithm).

**Parameters**

- **WindowHandle** (input_control) \(\sim\) handle
  Window handle.

- **Approximation** (input_control) \(\sim\) integer
  Maximum deviation from the original contour.
  Default value: 0
  Typical range of values: \(0 \leq\) Approximation
  Restriction: Approximation \(\geq\) 0

**Example**

* Calling...

  set_line_approx(WindowHandle,Approximation)
  set_draw(WindowHandle,'margin')
  disp_region(Obj,WindowHandle)

  * ...corresponds with

  get_region_polygon(Obj,Approximation,Row,Col)
  disp_polygon(WindowHandle,Row,Col)

**Result**

*set_line_approx* returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- query_insert, get_insert

**Possible Successors**

- disp_region

**See also**

- get_insert, query_insert

get_line_approx, set_line_style, set_draw, disp_region, disp_polygon

Module Foundation

```
set_lut_style ( : : WindowHandle, Hue, Saturation, Intensity : )
```

Changing the look-up-table (lut).

**set_lut_style** is obsolete and is only provided for reasons of backward compatibility.

**set_lut_style** changes the look-up-table (lut) of the device displaying the valid output window. It has got three parameters:

**Hue:** Rotation of color space, **Hue = 1.9** conforms to a one-time rotation of the color space. No changes: **Hue = 0.0** Complement colors: **Hue = 0.5**

**Saturation:** Changes of saturation, No changes: **Saturation = 1.0** Gray value image: **Saturation = 0.0**

**Intensity:** Changes of intensity, No changes: **Intensity = 1.0** Black image: **Intensity = 0.0**

Changes affect only the part of an look-up-table that is used for displaying images. The parameter of modification remain until the next call of **set_lut_style**. Calling **set_lut** has got no effect on these parameters.

```
Parameters
```

- **WindowHandle (input_control) :** Window handle.
- **Hue (input_control) :** Modification of color value.
  
  **Default value:** 0.0
  
  **Typical range of values:** 0.0 ≤ Hue ≤ 1.0
  
  **Restriction:** 0.0 >= Hue && Hue <= 1.0

- **Saturation (input_control) :** Modification of saturation.
  
  **Default value:** 1.5
  
  **Typical range of values:** 0.0 ≤ Saturation
  
  **Restriction:** 0.0 <= Saturation

- **Intensity (input_control) :** Modification of intensity.
  
  **Default value:** 1.5
  
  **Typical range of values:** 0.0 ≤ Intensity
  
  **Restriction:** 0.0 <= Intensity

```
Example
```

```
read_image(Image,'monkey')
dev_set_lut('color1')
repeat
  get_mbutton(WindowHandle,Row,Column,Button)
  Saturation := Row/300.0
  Hue := Column/512.0
  set_lut_style(WindowHandle,Hue,Saturation,1.0)
  dev_display(Image)
until(Button == 4)
```

**Result**

**set_lut_style** returns 2 (H_MSG_TRUE) if the window is valid and the parameter is correct. Otherwise an exception is raised.

---

**HALCON 20.11.0.0**
set_pixel ( : : WindowHandle, Pixel : )

Define a color lookup table index.

set_pixel is obsolete and is only provided for reasons of backward compatibility.

set_pixel sets pixel values: colors (set_color, set_rgb, etc.) and gray values (set_gray) are coded together into a number, called pixel. This 'pixel' is an index in the color lookup table. It ranges from 0 to 1 in b/w images and 0 to 255 color images with 8 bit planes. It is different from the 'pixel' ('picture element') in image processing. Therefore HALCON distinguishes between pixel and image element (or gray value).

The current value can be queried with get_pixel.

Parameters

- WindowHandle (input_control) .............................................. window ~ handle Window handle.
- Pixel (input_control) ...................................................... integer(-array) ~ integer Color lookup table index.
  Default value: 128
  Typical range of values: 0 ≤ Pixel ≤ 255

Result

set_pixel returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_pixel

generated with Sphinx
**17.7. GRAPHICS**

**set_tshape** ( : : WindowHandle, TextCursor : )

Set the shape of the text cursor.

**set_tshape** is obsolete and is only provided for reasons of backward compatibility.

**set_tshape** sets the shape and the display mode of the text cursor of the output window.

A text cursor marks the current position for text output. It is different from the mouse cursor (although both will be called ’cursor’, if the context makes misconceptions impossible). The available shapes for the text cursor can be queried with **query_tshape**.

```
Parameters

▷ WindowHandle (input_control) ................................. window  ~ handle
   Window handle.

▷ TextCursor (input_control) ................................. string  ~ string
   Name of cursor shape.
   Default value: ’invisible’
```

**Result**

**set_tshape** returns 2 (H_MSG_TRUE) if the window is valid and the given cursor shape is defined for this window. Otherwise an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

Foundation

---

**slide_image** ( : : WindowHandleSource1, WindowHandleSource2, WindowHandle : )

Interactive output from two window buffers.

The operator **slide_image** does not work with HDevelop graphics windows. It is only provided for reasons of backward compatibility.

**slide_image** divides the window horizontal in two logical areas dependent of the mouse position. The content of the first indicated window is copied in the upper area, the content of the second window is copied in the lower area. If you press the left mouse button you may scroll the delimitation between the two areas (you may move the mouse outside the window, too. In doing so the position of the mouse relative to the window determines the borderline).

Pressing the right mouse button in the window terminates the operator **slide_image**.

A useful application of the operator **slide_image** might be the visualization of the effect of a filtering operation for an image. The output is directed to the currently set window (WindowHandle).

**Attention**

The three windows must have the same size and have to reside on the same computer.
Parameters

- **WindowHandleSource1** (input_control) window handle of the “upper window”.
- **WindowHandleSource2** (input_control) window handle of the “lower window”.
- **WindowHandle** (input_control) Output window handle.

Example

read_image (Image, 'fabrik')
sobel_dir (Image, EdgeAmplitude, EdgeDirection, 'sum_abs', 3)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle1)
dev_display (EdgeAmplitude)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle2)
dev_display (EdgeDirection)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
slide_image (WindowHandle1, WindowHandle2, WindowHandle)

Result

If the both windows exist and one of these windows is valid slide_image returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- **open_window**
- **copy_rectangle**, **get_mposition**

Alternatives

- **open_window**, **move_rectangle**

**write_lut** ( : : WindowHandle, FileName : )

Write look-up-table (lut) as file.

**write_lut** is obsolete and is only provided for reasons of backward compatibility.

**write_lut** saves the look-up-table (resp. the part of it that is relevant for displaying image gray values) of the valid output window into a file named ‘FileName.lut’. It can be read again later with **set_lut**.

Attention

**write_lut** is only suitable for systems using 256 colors.

Parameters

- **WindowHandle** (input_control) window handle.
- **FileName** (input_control) File name (of file containing the look-up-table).
  
  Default value: ’/tmp/lut’
  
  File extension: .lut
17.8. MATCHING

write_lut returns 2 (H_MSG_TRUE) if the window with the required properties (256 colors) is valid and the parameter (file name) is correct. Otherwise an exception is raised.

Result

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

17.8 Matching

adapt_template(Image: : TemplateID :)

Adapting a template to the size of an image.

adapt_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator adapt_template serves to adapt a template which has been created by create_template to the size of an image. The operator adapt_template can be called before the template is used with images of another size, or if the image used to create the template had another size. If it is not called explicitly it will be called internally each time another image size is used. The contents of the image is hereby irrelevant; only the width of Image will be considered.

Parameters

- Image (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . singlechannelimage(-array) \sim object: byte
  Image which determines the size of the later matching.
- TemplateID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . template \sim handle
  Template number.

Result

If the parameter values are correct, the operator adapt_template returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_template, create_template_rot, read_template

Possible Successors

set_reference_template, best_match, fast_match, fast_match_mg,
Matching

**best_match** (Image : : TemplateID, MaxError, SubPixel : Row, Column, Error)

Searching the best matching of a template and an image.

**best_match** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **best_match** performs a matching of the template of TemplateID and Image. Hereby the template will be moved over the points of Image so that the template will lie always inside Image. best_match works similar to fast_match, with the exception, that each time a better match is found the value of MaxError is internally updated to a lower value to reduce runtime.

With regard to the parameter SubPixel, the position will be indicated by subpixel accuracy. The matching criterion (“displaced frame difference”) is defined as follows:

\[
error[\text{row}, \text{col}] = \frac{\sum_{u,v} |\text{Image}[\text{row} - u, \text{col} - v] - \text{TemplateID}[u, v]|}{\text{area(TemplateID)}}
\]

The runtime of the operator depends on the size of the domain of Image. Therefore it is important to restrict the domain as far as possible, i.e. to apply the operator only in a very confined “region of interest”. The parameter MaxError determines the maximal error which the searched position is allowed to have at most. The lower this value is, the faster the operator runs.

Row and Column return the position of the best match, whereby Error indicates the average difference of the gray values. If no position with an error below MaxError was found the position (0, 0) and a matching result of 255 for Error are returned. In this case MaxError has to be set larger.

The maximum error of the position (without noise) is 0.1 pixel. The average error is 0.03 pixel.

**Parameters**

- **Image** (input_object) .......................................................singlechannelimage(-array) ~ object : byte
  Input image inside of which the pattern has to be found.
- **TemplateID** (input_control) ............................................template ~ handle
  Template number.
- **MaxError** (input_control) ............................................... real ~ real
  Maximum average difference of the gray values.
  Default value: 20.0
  Suggested values: MaxError ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
  Typical range of values: 0 ≤ MaxError ≤ 255
  Minimum increment: 1
  Recommended increment: 3
- **SubPixel** (input_control) ..................................................string ~ string
  Subpixel accuracy in case of ‘true’.
  Default value: ‘false’
  List of values: SubPixel ∈ {'true', 'false'}
- **Row** (output_control) .....................................................point.y(-array) ~ real
  Row position of the best match.
- **Column** (output_control) ................................................point.x(-array) ~ real
  Column position of the best match.
- **Error** (output_control) ..................................................real(-array) ~ real
  Average divergence of the gray values of the best match.
If the parameter values are correct, the operator `best_match` returns the value 2 (H_MSG_TRUE).

If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Matching

```plaintext
best_match_mg ( Image : : TemplateID, MaxError, SubPixel,
                 NumLevels, WhichLevels : Row, Column, Error )
```

Searching the best gray value matches in a pyramid.

`best_match_mg` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`best_match_mg` applies gray value matching using an image pyramid. `best_match_mg` works analogously to `best_match`, but it is faster due to the use of a pyramid. Input is an image with an optionally reduced domain. The template is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image. The parameter `MaxError` specifies the maximum error for template matching. Using smaller values results in a reduced runtime but it is possible that the pattern might be missed. The value of `MaxError` has to be chosen larger compared with `best_match`, because the error at higher levels of the pyramid is often larger.

`SubPixel` specifies if the result is calculated with sub pixel accuracy or not. A value of 1 for `NumLevels` results in an operator similar to `best_match`, i.e. only the original gray values are used. For values larger than 1, the algorithm starts at the lowest resolution and searches for a position with the lowest matching error. At the next higher resolution this position is refined. This is continued up to the maximum resolution (`WhichLevels = 'all'`). As an alternative Method the mode `WhichLevels` with value 'original' can be used. In this case not only the position with the lowest error but all points below `MaxError` are analyzed further on in the next higher resolution. This method is slower but it is more stable and the possibility to miss the correct position is very low. In this case it is often possible to start with a lower resolution (higher level in Pyramid, i.e. larger value for `NumLevels`) which leads to a reduced runtime. Besides the values 'all' and 'original' for `WhichLevels` you can specify the pyramid level explicitly where to switch between a “match all” and the "best match". Here 0 corresponds to 'original' and `NumLevels - 1` is equivalent to 'all'. A value in-between is in most cases a good compromise between speed and a stable detection. A larger value for `WhichLevels` results in a reduced runtime, a smaller value results in a more stable detection. The value of `NumLevels` has to be equal or smaller than the value used to create the template.

The position of the found matching position is returned in `Row` and `Column`. The corresponding error is given in `Error`. If no point below `MaxError` is found a value of 255 for `Error` and 0 for `Row` and `Column` is returned. If the desired object is missed (no object found or wrong position) you have to set `MaxError` higher or `WhichLevels` lower. Check also if the illumination has changed (see `set_offset_template`).

The maximum error of the position (without noise) is 0.1 pixel. The average error is 0.03 pixel.
Parameters

- **Image** (input_object) .......................... singlechannelimage(-array) \(\Rightarrow\) object : byte
  Input image inside of which the pattern has to be found.

- **TemplateID** (input_control) .......................... template \(\Rightarrow\) handle
  Template number.

- **MaxError** (input_control) .......................... real \(\Rightarrow\) real
  Maximal average difference of the gray values.
  Default value: 30.0
  Suggested values: \(\text{MaxError} \in \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0\}\)
  Typical range of values: \(0 \leq \text{MaxError} \leq 255\)
  Minimum increment: 1
  Recommended increment: 3

- **SubPixel** (input_control) .......................... string \(\Rightarrow\) string
  Exactness in subpixels in case of ‘true’.
  Default value: ’false’
  List of values: SubPixel \(\in \{’true’, ’false’\}\)

- **NumLevels** (input_control) .......................... integer \(\Rightarrow\) integer
  Number of the used resolution levels.
  Default value: 4
  Suggested values: \(\text{NumLevels} \in \{1, 2, 3, 4, 5, 6\}\)

- **WhichLevels** (input_control) .......................... integer / string
  Resolution level up to which the method “best match” is used.
  Default value: 2
  Suggested values: \(\text{WhichLevels} \in \{’all’, ’original’, 0, 1, 2, 3, 4, 5, 6\}\)

- **Row** (output_control) .......................... point.y \(\Rightarrow\) real
  Row position of the best match.

- **Column** (output_control) .......................... point.x \(\Rightarrow\) real
  Column position of the best match.

- **Error** (output_control) .......................... real \(\Rightarrow\) real
  Average divergence of the gray values in the best match.

Result

If the parameter values are correct, the operator **best_match_mg** returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via **set_system** (’no_object_result’,<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

- create_template, read_template, adapt_template, draw_region, draw_rectangle1, reduce_domain, set_reference_template, set_offset_template

Alternatives

- fast_match, fast_match_mg, best_match, best_match_pre_mg, best_match_rot, best_match_rot_mg, exhaustive_match, exhaustive_match_mg

Module

**best_match_pre_mg** ( ImagePyramid : : TemplateID, MaxError, SubPixel, NumLevels, WhichLevels : Row, Column, Error )

Searching the best gray value matches in a pre generated pyramid.
best_match_pre_mg is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

best_match_pre_mg applies gray value matching using an image pyramid. best_match_pre_mg works analogously to best_match_mg, but it makes use of pre calculated pyramid which has to be generated beforehand using gen_gauss_pyramid. This reduces runtime if more than one match has to be done or the pyramid has been used otherwise. The pyramid has to be generated using the zooming factor 0.5 and the mode 'constant'.

Parameters

- **ImagePyramid** (input_object) singlechannelimage-array  \( \Rightarrow \) object : byte
  Image pyramid inside of which the pattern has to be found.
- **TemplateID** (input_control) template  \( \Rightarrow \) handle
  Template number.
- **MaxError** (input_control) real  \( \Rightarrow \) real
  Maximal average difference of the gray values.
  Default value: 30.0
  Suggested values: MaxError \( \in \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0\}\)
  Typical range of values: \( 0 \leq \text{MaxError} \leq 255 \)
  Minimum increment: 1
  Recommended increment: 3
- **SubPixel** (input_control) string  \( \Rightarrow \) string
  Exactness in subpixels in case of 'true'.
  Default value: 'false'
  List of values: SubPixel \( \in \{\text{true}', \text{false}'\}\)
- **NumLevels** (input_control) integer  \( \Rightarrow \) integer
  Number of the used resolution levels.
  Default value: 3
  Suggested values: NumLevels \( \in \{1, 2, 3, 4, 5, 6\}\)
- **WhichLevels** (input_control) integer / string
  Resolution level up to which the method "best match" is used.
  Default value: 'original'
  Suggested values: WhichLevels \( \in \{\text{all}', \text{original}', 0, 1, 2, 3, 4, 5, 6\}\)
- **Row** (output_control) point.y  \( \Rightarrow \) real
  Row position of the best match.
- **Column** (output_control) point.x  \( \Rightarrow \) real
  Column position of the best match.
- **Error** (output_control) real  \( \Rightarrow \) real
  Average divergence of the gray values in the best match.

Result

If the parameter values are correct, the operator best_match_pre_mg returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result', <Result>). If necessary, an exception is raised.

Module

Matching
Searching the best matching of a template and an image with rotation.

**best_match_rot** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **best_match_rot** performs a matching of the template of TemplateID and Image. It works similar to **best_match** with the extension that the pattern can be rotated. The parameters AngleStart and AngleExtend define the maximum rotation of the pattern: AngleStart specifies the maximum counterclockwise rotation and AngleExtend the maximum clockwise rotation relative to this angle. Both values have to be smaller or equal to the values used for the creation of the pattern (see create_template_rot). In addition to best_match best_match_rot returns the rotation angle of the pattern in Angle (radian). The accuracy of this angle depends on the parameter AngleStep of create_template_rot. In the case of SubPixel = 'true' the position and the angle are calculated with “sub pixel” accuracy.

```
best_match_rot ( Image : : TemplateID, AngleStart, AngleExtend,
                MaxError, SubPixel : Row, Column, Angle, Error )
```

Parameters

- **Image** (input_object) : singlechannelimage(-array) \( \sim \) object : byte
  Input image inside of which the pattern has to be found.
- **TemplateID** (input_control) : handle
  Template number.
- **AngleStart** (input_control) : angle.rad \( \sim \) real
  Smallest Rotation of the pattern.
  Default value: -0.39
  Suggested values: AngleStart \( \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)
- **AngleExtend** (input_control) : angle.rad \( \sim \) real
  Maximum positive Extension of AngleStart.
  Default value: 0.79
  Suggested values: AngleExtend \( \in \{6.28, 3.14, 1.57, 0.79, 0.39\}\)
  Restriction: AngleExtend > 0
- **MaxError** (input_control) : real \( \sim \) real
  Maximum average difference of the gray values.
  Default value: 30.0
  Suggested values: MaxError \( \in \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0\}\)
  Typical range of values: 0 \( \leq \) MaxError \( \leq \) 255
  Minimum increment: 1
  Recommended increment: 3
- **SubPixel** (input_control) : string \( \sim \) string
  Subpixel accuracy in case of 'true'.
  Default value: 'false'
  List of values: SubPixel \( \in \{'true', 'false'\}\)
- **Row** (output_control) : point.y(-array) \( \sim \) real
  Row position of the best match.
- **Column** (output_control) : point.x(-array) \( \sim \) real
  Column position of the best match.
- **Angle** (output_control) : angle.rad(-array) \( \sim \) real
  Rotation angle of pattern.
- **Error** (output_control) : real(-array) \( \sim \) real
  Average divergence of the gray values of the best match.

Result

If the parameter values are correct, the operator **best_match_rot** returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system (‘no_object_result’,<Result>). If necessary, an exception is raised.

Execution Information

Module

**best_match_rot** ( Image : TemplateID, AngleStart, AngleExtend, MaxError, SubPixel, NumLevels : Row, Column, Angle, Error )

Searching the best matching of a template and a pyramid with rotation.

**best_match_rot** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **best_match_rot** performs a matching of the template of TemplateID and Image. It works similar to **best_match_mg** with the extension that the pattern can be rotated analogously to **best_match_rot**. The parameters AngleStart and AngleExtend define the maximum rotation of the pattern: AngleStart specifies the maximum counter clockwise rotation and AngleExtend the maximum clockwise rotation relative to this angle. Both values have to smaller or equal to the values used for the creation of the pattern (see create_template_rot). In addition to **best_match_mg** **best_match_rot** returns the rotation angle of the pattern in Angle (radian).

The value of MaxError must be set larger in comparison with the operator **best_match_rot**, because often the error is larger at higher levels of the pyramid.

In the case of SubPixel = 'true' the position and the angle are calculated with “sub pixel” accuracy.

The value of NumLevels has to equal or smaller than the value used to create the template.

Parameters

▷ **Image** (input_object) ......................... singlechannelimage(-array) $\sim$ object : byte
Input image inside of which the pattern has to be found.

▷ **TemplateID** (input_control) .................. template $\sim$ handle
Template number.

▷ **AngleStart** (input_control) .................... angle.rad $\sim$ real
Smallest Rotation of the pattern.
Default value: -0.39
Suggested values: AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]

▷ **AngleExtend** (input_control) ................... angle.rad $\sim$ real
Maximum positive Extension of AngleStart.
Default value: 0.79
Suggested values: AngleExtend ∈ [6.28, 3.14, 1.57, 0.79, 0.39]
Restriction: AngleExtend > 0

▷ **MaxError** (input_control) ....................... real $\sim$ real
Maximum average difference of the gray values.
Default value: 40.0
Suggested values: MaxError ∈ [0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0]
Typical range of values: 0 ≤ MaxError ≤ 255
Minimum increment: 1
Recommended increment: 1
CHAPTER 17 LEGACY

SubPixel (input_control) ................................................................. string  \(\rightarrow\) string
Subpixel accuracy in case of 'true'.
Default value: 'false'
List of values: SubPixel \(\in\) {'true', 'false'}

NumLevels (input_control) ............................................................. integer  \(\rightarrow\) integer
Number of the used resolution levels.
Default value: 3
Suggested values: NumLevels \(\in\) \{1, 2, 3, 4, 5, 6\}

Row (output_control) ................................................................. point.y(-array)  \(\rightarrow\) real
Row position of the best match.

Column (output_control) ............................................................. point.x(-array)  \(\rightarrow\) real
Column position of the best match.

Angle (output_control) .............................................................. angle.rad(-array)  \(\rightarrow\) real
Rotation angle of pattern.

Error (output_control) ............................................................. real(-array)  \(\rightarrow\) real
Average divergence of the gray values of the best match.

If the parameter values are correct, the operator best_match_rot_mg returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Module

Matching

clear_template ( : : TemplateID : )

Deallocation of the memory of a template.
clear_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator clear_template deallocates the memory of a template which has been created by create_template or create_template_rot. After execution of the operator clear_template the template can no longer be used. The value of TemplateID is not valid. However, the number can be used again by further calls of create_template or create_template_rot.

Parameters

TemplateID (input_control) ......................................................... template  \(\rightarrow\) handle
Template number.

Result

If the number of the template is valid, the operator clear_template returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_template, create_template_rot, read_template, write_template

Module
Matching

create_template ( Template : : FirstError, NumLevel, Optimize,
GrayValues : : TemplateID )

Preparing a pattern for template matching.

create_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator create_template preprocesses a pattern (Template), which is passed as an image, for the template matching. After the transformation, a number (TemplateID) is assigned to the template for being used in the further process. The shape and the size of Template can be chosen arbitrarily. You have to be aware, that the matching is only applied to that part of an image where Template fits completely into the image.

The template has been chosen such that it contains no pixels of the (changing) background. Here you can make use of the arbitrary shape of a template which is not restricted to a rectangle. To create a template region you can use segmentation operators like threshold or one of the draw_* operators. In the case of sub pixel accurate matching Template has in addition to be one pixel smaller than the pattern (i.e. one pixel border to the changing background). This can be done e.g. by applying the operator erosion_circle.

The parameter NumLevel specifies the number of pyramid levels (NumLevel = 1 means only original gray values) which can be used for matching. The number of levels used later for matching will be below or equal this value. If the pattern becomes too small due to zooming, the maximum number of pyramid levels is automatically reduced (without error message).

The parameter GrayValues defines, whether the original gray values ('original', 'normalized') or the edge amplitude ('gradient', 'sobel') is used. With 'original' the sum of the differences is used as feature which is very stable and fast if there is no change in illumination. 'normalized' is used if the illumination changes. The method is a bit slower and not quite as stable. Note that 'normalized' allows to compensate additive illumination changes. If also multiplicative variations of the gray values occur, correlation-based matching should be used (create_ncc_model). If there is no change in illumination the mode 'original' should be used. The edge amplitude is another method to be invariant to changes in illumination. The disadvantage is the increased execution time and the higher sensitivity to changes in the shape of the pattern. The mode 'gradient' is slightly faster but more sensitive to noise.

The maximum error for matching has typically to be chosen higher when using the edge amplitude. The mode chosen by GrayValues leads automatically to calling the appropriate filter during the matching, if necessary.

As an alternative to the gradient approach the operator set_offset_template can be used, if the change in illumination is known.

The parameter Optimize specifies if the pattern has to be optimized for runtime. This optimization results in a longer time to create the template but reduces the time for matching. In addition the optimization leads to a more stable matching, i.e., the possibility to miss good matches is reduced. The optimization process selects the most stable and significant gray values to be tested first during the matching process. Using this technique a wrong match can be eliminated very early.

The reference position for the template is its center of gravity. I.e. if you apply the template to the original image the center of gravity is returned. This default reference can be adapted using the operator set_reference_template.
In sub pixel mode a special position correction is calculated which is added after each matching: The template is applied to the original image and the difference between the found position and the center of gravity is used as a correction vector. This is important for patterns in a textured context or for asymmetric pattern. For most templates this correction vector is near null.

Before the use of the template, which is stored independently of the image size, it can be adapted explicitly to the size of a definite image size by using adapt_template.

---

### Parameters

- **Template** (input_object) : singlechannelimage
  - Input image whose domain will be processed for the pattern matching.
- **FirstError** (input_control) : integer
  - Not yet in use.
  - Default value: 255
  - List of values: FirstError ∈ {255}
- **NumLevel** (input_control) : integer
  - Maximal number of pyramid levels.
  - Default value: 4
  - List of values: NumLevel ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- **Optimize** (input_control) : string
  - Kind of optimizing.
  - Default value: 'sort'
  - List of values: Optimize ∈ {'none', 'sort'}
- **GrayValues** (input_control) : string
  - Kind of gray values.
  - Default value: 'original'
  - List of values: GrayValues ∈ {'original', 'normalized', 'gradient', 'sobel'}
- **TemplateID** (output_control) : template
  - Template number.

---

### Result

If the parameters are valid, the operator create_template returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

---

### Possible Predecessors

draw_region, reduce_domain, threshold

### Possible Successors

adapt_template, set_reference_template, clear_template, write_template,
set_offset_template, best_match, best_match_mg, fast_match, fast_match_mg

### Alternatives

create_ncc_model, create_template_rot, read_template

### Module

Matching

---

**create_template_rot** ( Template : : NumLevel, AngleStart,
  AngleExtend, AngleStep, Optimize, GrayValues : TemplateID )

**Preparing a pattern for template matching with rotation.**
create_template_rot is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator create_template_rot preprocesses a pattern, which is passed as an image, for the template matching. An extension to create_template the matching can applied to rotated patterns. The parameters \( \text{AngleStart} \) and \( \text{AngleExtend} \) define the maximum rotation of the pattern: \( \text{AngleStart} \) specifies the maximum counter clockwise rotation and \( \text{AngleExtend} \) the maximum clockwise rotation relative to this angle. Therefore \( \text{AngleExtend} \) has to be smaller than \( 2\pi \). With the parameter \( \text{AngleStep} \) the maximum angle resolution (on the highest resolution level) can be specified.

You have to be aware, that all possible rotations are calculated beforehand to reduce runtime during matching. This leads to a higher execution time for create_template_rot and high memory requirements for the template. The amount of memory depends on the parameters \( \text{AngleExtend} \) and \( \text{AngleStep} \). The number of pyramid levels can be neglected. If \( A \) is the number of pixels of Template, the memory \( M \) needed for the template in byte is about:

\[
M = \frac{4 \times 12 \times \text{AngleExtend}}{\text{AngleStep}}
\]

After the transformation, a number (TemplateID) is assigned to the template for being used in the further process.

A description of the other parameters can be found at the operator create_template.

---

Attention

You have to be aware, that depending on the resolution a large number of pre calculated patterns have to be created which might result in a large amount of memory needed.

---

Parameters

- **Template** (input_object) ... singlechannelimage \( \rightsarrow \) byte
  - Input image whose domain will be processed for the pattern matching.

- **NumLevel** (input_control) ... integer \( \rightsarrow \) integer
  - Maximal number of pyramid levels.
  - Default value: 4
  - List of values: NumLevel \( \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\} \)

- **AngleStart** (input_control) ... angle.rad \( \rightsarrow \) real
  - Smallest Rotation of the pattern.
  - Default value: -0.39
  - Suggested values: AngleStart \( \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\} \)

- **AngleExtend** (input_control) ... angle.rad \( \rightsarrow \) real
  - Maximum positive Extension of AngleStart.
  - Default value: 0.79
  - Suggested values: AngleExtend \( \in \{6.28, 3.14, 1.57, 0.79, 0.39\} \)
  - Restriction: AngleExtend > 0

- **AngleStep** (input_control) ... angle.rad \( \rightsarrow \) real
  - Step rate (angle precision) of matching.
  - Default value: 0.0982
  - Suggested values: AngleStep \( \in \{0.3927, 0.1963, 0.0982, 0.0491, 0.0245\} \)
  - Restriction: AngleStep > 0

- **Optimize** (input_control) ... string \( \rightsarrow \) string
  - Kind of optimizing.
  - Default value: ’sort’
  - List of values: Optimize \( \in \{’none’, ’sort’\} \)

- **GrayValues** (input_control) ... string \( \rightsarrow \) string
  - Kind of gray values.
  - Default value: ’original’
  - List of values: GrayValues \( \in \{’original’, ’normalized’, ’gradient’, ’sobel’\} \)

- **TemplateID** (output_control) ... template \( \rightsarrow \) handle
  - Template number.
If the parameters are valid, the operator `create_template_rot` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Predecessors**

- `draw_region`, `reduce_domain`, `threshold`

**Possible Successors**

- `best_match_rot`, `best_match_rot_mg`, `adapt_template`, `set_reference_template`, `clear_template`, `set_offset_template`, `write_template`

**Alternatives**

- `create_ncc_model`, `create_template`

**Module**

**deserialize_template** ( : : SerializedItemHandle : TemplateID )

Deserializes a serialized template.

`deserialize_template` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`deserialize_template` deserializes a template, that was serialized by `serialize_template` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized template is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created template with the handle `TemplateID`.

**Parameters**

- **SerializedItemHandle** (input_control) .......... serialized_item ~ handle Handle of the serialized item.
- **TemplateID** (output_control) .................. template ~ handle Template number.

If the parameters are valid, the operator `deserialize_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `fread_serialized_item`, `receive_serialized_item`, `serialize_template`

**Possible Successors**

- `adapt_template`, `set_reference_template`, `set_offset_template`, `best_match`, `fast_match`, `best_match_rot`

**Module**

**Matching**
fast_match ( Image : Matches : TemplateID, MaxError : )

Searching all good matches of a template and an image.

fast_match is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator fast_match performs a matching of the template of TemplateID and Image. Hereby the template will be moved over the points of Image so that the template always lies completely inside of Image. The matching criterion ("displaced frame difference") is defined as follows:

\[
\text{error}_{\text{row, col}} = \frac{\sum_{u,v} |\text{Image}_{\text{row} - u, \text{col} - v} - \text{TemplateID}_{u, v}|}{\text{area}(\text{TemplateID})}
\]

The difference between fast_match and exhaustive_match is that the matching for one position is stopped if the error is too high. This leads to a reduced runtime but one might miss correct matches. The runtime of the operator depends mainly on the size of the domain of Image. Therefore it is important to restrict the domain as far as possible, i.e. to apply the operator only in a very confined "region of interest". The parameter MaxError determines the maximal error which the searched position is allowed to show. The lower this value is, the faster the operator runs.

All points which show a matching error smaller than MaxError will be returned in the output region Matches. This region can be used for further processing. For example by using a connection and best_match to find all the matching objects. If no point has a match error below MaxError the empty region (i.e no points) is returned.

--- Parameters ---

▷ Image (input_object) ............................. singlechannelimage(-array)  \sim object : byte
  Input image inside of which the pattern has to be found.

▷ Matches (output_object) ............................. region(-array)  \sim object
  All points whose error lies below a certain threshold.

▷ TemplateID (input_control) ............................. template  \sim handle
  Template number.

▷ MaxError (input_control) ............................. real  \sim real
  Maximal average difference of the gray values.

  Default value: 20.0
  Suggested values: \( \text{MaxError} \in \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0\} \)
  Typical range of values: \( 0 \leq \text{MaxError} \leq 255 \)
  Minimum increment: 1
  Recommended increment: 1

--- Result ---

If the parameter values are correct, the operator fast_match returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

--- Execution Information ---

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

--- Possible Predecessors ---

create_template, read_template, adapt_template, draw_region, draw_rectangle1, reduce_domain

--- Possible Successors ---

connection, best_match

--- Alternatives ---

best_match, best_match_mg, fast_match_mg, exhaustive_match, exhaustive_match_mg

Module

HALCON 20.11.0.0
**fast_match_mg** (Image : Matches : TemplateID, MaxError, NumLevel : )

Searching all good gray value matches in a pyramid.

**fast_match_mg** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **fast_match_mg** like the operator **fast_match** performs a matching of the template of TemplateID and Image. In contrast to **fast_match**, however, the search for good matches starts in scaled down images (pyramid). The number of levels of the pyramid will be determined by NumLevel. Hereby the value 1 indicates that no pyramid will be used. In this case the operator **fast_match_mg** is equivalent to the operator **fast_match**. The value 2 triggers the search in the image with half the framesize. The search for all those points showing an error small enough in the scaled down image (error smaller than MaxError) will be refined at the corresponding positions in the original image (Image).

The runtime of matching depends on the parameter MaxError: the larger the value the longer is the processing time, because more points of the pattern have to be tested. If MaxError is to low the pattern will not be found. The value has therefore to be optimized for every application.

NumLevel indicates the number of levels of the pyramid, including the original image. Optionally a second value can be given. This value specifies the number (0..n) of the lowest level which is used the matching. The region found up to this level will then be zoomed to the size of the original level. This can used to increase the runtime in the case that the accuracy does not have to be so high.

### Parameters

- **Image** (input_object) ............................... singlechannelimage(-array) \(\sim object : byte\)
  Input image inside of which the pattern has to be found.
- **Matches** (output_object) .......................... region(-array) \(\sim object\)
  All points which have an error below a certain threshold.
- **TemplateID** (input_control) ........................ template \(\sim handle\)
  Template number.
- **MaxError** (input_control) ........................... real \(\sim real\)
  Maximal average difference of the gray values.
  Default value: 30.0
  Suggested values: MaxError \(\in\) {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
  Typical range of values: 0 \(\leq\) MaxError \(\leq\) 255
  Minimum increment: 1
  Recommended increment: 3
- **NumLevel** (input_control) ............................ integer(-array) \(\sim integer\)
  Number of levels in the pyramid.
  Default value: 3
  Suggested values: NumLevel \(\in\) {1, 2, 3, 4, 5, 6, 7, 8}

### Result

If the parameter values are correct, the operator **fast_match_mg** returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

create_template, read_template, adapt_template, draw_region, draw_rectangle1, reduce_domain

### Alternatives

best_match, best_match_mg, fast_match, exhaustive_match, exhaustive_match_mg
**read_template** ( : : FileName : TemplateID )

Reading a template from file.

**read_template** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator **read_template** reads a matching template from file which has been written with **write_template**. The default HALCON file extension for a template is `.gvt`.

<table>
<thead>
<tr>
<th><strong>Parameters</strong></th>
</tr>
</thead>
</table>
| **FileName** (input_control) | filename.read  \(\sim\) string file name.  
  File extension: `.gvt` |
| **TemplateID** (output_control) | template \(\sim\) handle Template number. |

<table>
<thead>
<tr>
<th><strong>Result</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>If the file name is valid, the operator <strong>read_template</strong> returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.</td>
</tr>
</tbody>
</table>

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Successors**

---

**serialize_template** ( : : TemplateID : SerializedItemHandle )

Serialize a template.

**serialize_template** is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

**serialize_template** serializes the data of a template (see **fwrite_serialized_item** for an introduction of the basic principle of serialization). The same data that is written in a file by **write_template** is converted to a serialized item. The template is defined by the handle **TemplateID**. The serialized template is returned by the handle **SerializedItemHandle** and can be deserialized by **deserialize_template**.

<table>
<thead>
<tr>
<th><strong>Parameters</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TemplateID</strong> (input_control)</td>
</tr>
<tr>
<td><strong>SerializedItemHandle</strong> (output_control)</td>
</tr>
</tbody>
</table>
If the parameters are valid, the operator `serialize_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

`create_template`, `create_template_rot`

### Possible Successors

`fwrite_serialized_item`, `send_serialized_item`, `deserialize_template`

### Module

`Matching`

### Parameters

- **TemplateID** (input_control) template handle
- **GrayOffset** (input_control) number integer

  Default value: 0
  
  Suggested values: \( \text{GrayOffset} \in \{-10, -5, -2, -1, 0, 1, 2, 5, 10\} \)

  Typical range of values: \(-255 \leq \text{GrayOffset} \leq 255\)

  Minimum increment: 1

  Recommended increment: 1

### Result

If the parameter values are correct, the operator `set_offset_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **TemplateID**

---

**set_offset_template** ( : : TemplateID, GrayOffset : )

Gray value offset for template.

`set_offset_template` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`set_offset_template` adds a gray value offset to the template to eliminate gray value changes in the image. The parameter `GrayOffset` specifies a difference relative to the gray values of the pattern when it was created with `create_template` (not relative to the last call of `set_offset_template`). The values of `GrayOffset` have to be chosen according to the gray values of the image: A brighter image results in a positive value, a darker image results in a negative value. `set_offset_template` has to be called each time the gray values of the image changes. The gray values can be measured in a reference area using `intensity` or `min_max_gray`
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

possible predecessors
create_template, adapt_template, read_template
possible successors
best_match, best_match_mg, best_match_rot, fast_match, fast_match_mg

Module

set_reference_template ( : : TemplateID, Row, Column : )

Define reference position for a matching template.

set_reference_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

set_reference_template allows to define a new reference position for a template. As default after calling create_template or create_template_rot the center of gravity of the template is used. Using set_reference_template the reference position can be redefined. In the case of the center of gravity as reference the vector (0, 0) is returned after matching for a null translation of the pattern relative to the image.

parameters

- TemplateID (input_control) template handle
  Template number.
- Row (input_control) point.y real
  Reference position of template (row).
- Column (input_control) point.x real
  Reference position of template (column).

result
If the parameter values are correct, the operator set_reference_template returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

execution information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

possible predecessors
create_template, create_template_rot, read_template, adapt_template
possible successors
best_match, best_match_mg, best_match_rot, fast_match, fast_match_mg

Module

write_template ( : : TemplateID, FileName : )

Writing a template to file.
write_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator write_template writes a matching template to file which can be read again with read_template. The default HALCON file extension for a template is 'gvt'.

Parameters

▷ TemplateID (input_control) template ~ handle
  Template number.

▷ FileName (input_control) filename.write ~ string
  File name.
  File extension: .gvt

Result

If the file name is valid (permission to write), the operator write_template returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

create_template, create_template_rot

Module

17.9 Morphology

closing_golay ( Region : RegionClosing : GolayElement, Rotation : )

Close a region with an element from the Golay alphabet.

closing_golay is obsolete and is only provided for reasons of backward compatibility.

closing_golay is defined as a Minkowski addition followed by a Minkowski subtraction. First the Minkowski addition of the input region (Region) with the structuring element from the Golay alphabet defined by GolayElement and Rotation is computed. Then the Minkowski subtraction of the result and the structuring element rotated by 180° is performed.

The following structuring elements are available:
'1', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number Rotation determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

closing_golay serves to close holes smaller than the structuring element, and to smooth regions’ boundaries.

Attention

Not all values of Rotation are valid for any Golay element. For some of the values of Rotation, the resulting regions are identical to the input regions.

Parameters

▷ Region (input_object) region(-array) ~ object
  Regions to be closed.

▷ RegionClosing (output_object) region(-array) ~ object
  Closed regions.
GolayElement (input_control) .......................... string  string
Structuring element from the Golay alphabet.

Default value: 'h'
List of values: GolayElement ∈ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

Rotation (input_control) ................................ integer  integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.

Default value: 0
List of values: Rotation ∈ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \]

closing_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

**Module**

Foundation

dilation_golay ( Region : RegionDilation : GolayElement, Iterations, Rotation : )

dilate a region with an element from the Golay alphabet.

dilation_golay is obsolete and is only provided for reasons of backward compatibility.

dilation_golay dilates a region with the selected element GolayElement from the Golay alphabet. The following structuring elements are available:

' l ', ' m ', ' d ', ' c ', ' e ', ' i ', ' f ', ' f2 ', ' h ', ' k '.

The rotation number Rotation determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements. The operator works by shifting the structuring element over the region to be processed (Region). For all positions of the structuring element that
intersect the region, the corresponding reference point (relative to the structuring element) is added to the output
region. This means that the union of all translations of the structuring element within the region is computed.

The parameter Iterations determines the number of iterations which are to be performed with the structuring
element. The result of iteration \( n - 1 \) is used as input for iteration \( n \).

---

Attention

Not all values of Rotation are valid for any Golay element. For some of the values of Rotation, the resulting
regions are identical to the input regions.

---

Parameters

- **Region** (input_object) .......................... region(-array) \( \sim \) object
  Regions to be dilated.
- **RegionDilation** (output_object) ................. region(-array) \( \sim \) object
  Dilated regions.
- **GolayElement** (input_control) .................. string \( \sim \) string
  Structuring element from the Golay alphabet.
  Default value: ‘h’
- **Iterations** (input_control) ...................... integer \( \sim \) integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations \( \in \) \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
  Typical range of values: \( 1 \leq \) Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Rotation** (input_control) ....................... integer \( \sim \) integer
  Rotation of the Golay element. Depending on the element, not all rotations are valid.
  Default value: 0
  List of values: Rotation \( \in \) \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}

---

Complexity

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[
O(3 \cdot \sqrt{F})
\]

---

Result

dilation_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no
input region can be set via:

- no region:
  ```
  set_system(‘no_object_result’,<RegionResult>)
  ```
- empty region:
  ```
  set_system(‘empty_region_result’,<RegionResult>)
  ```

Otherwise, an exception is raised.

---

thickening_golay, golay_elements

Module

Foundation

dilation_seq ( Region : RegionDilation : GolayElement,

   Iterations : )

dilate a region sequentially.

dilation_seq is obsolete and is only provided for reasons of backward compatibility.

dilation_seq computes the sequential dilation of the input region Region with the selected structuring element GolayElement from the Golay alphabet. This is done by executing the operator dilation_golay with all rotations of the structuring element Iterations times. The following structuring elements can be selected: 'l', 'd', 'c', 'f', 'h', 'k'.

In order to compute the skeleton of a region, usually the elements 'l' and 'm' are used. Only the “foreground elements” (even rotation numbers) are used. The elements 'i' and 'e' result in unchanged output regions. The elements 'l', 'm' and 'f2' are identical for the foreground. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

Parameters

- Region (input_object) .......... region(-array) ~ object
  Regions to be dilated.
- RegionDilation (output_object) .......... region(-array) ~ object
  Dilated regions.
- GolayElement (input_control) .......... string ~ string
  Structuring element from the Golay alphabet.
  Default value: ‘h’
  List of values: GolayElement ∈ {'l', 'd', 'c', 'f', 'h', 'k'}
- Iterations (input_control) .......... integer ~ integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
  Typical range of values: 1 ≤ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

Complexity

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[
O(\text{Iterations} \cdot 20 \cdot \sqrt{F})
\]

Result

dilation_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors
threshold, region growing, connection, union1, watersheds, class ndim norm

Possible Successors
reduce domain, select shape, area center, connection

Alternatives
dilation1, dilation2, dilation_golay

Module
Foundation

**erosion_golay** ( Region : RegionErosion : GolayElement, Iterations, Rotation : )

Erode a region with an element from the Golay alphabet.

erosion_golay is obsolete and is only provided for reasons of backward compatibility.

The rotation number *Rotation* determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator *golay_elements*. The operator works by shifting the structuring element over the region to be processed (*Region*). For all positions of the structuring element fully contained in the region, the corresponding reference point (relative to the structuring element) is added to the output region. This means that the intersection of all translations of the structuring element within the region is computed.

The parameter *Iterations* determines the number of iterations which are to be performed with the structuring element. The result of iteration *n* − 1 is used as input for iteration *n*.

Attention
Not all values of *Rotation* are valid for any Golay element. For some of the values of *Rotation*, the resulting regions are identical to the input regions.

Parameters

- **Region** (input_object) .................................................. region(-array) \(\sim\) object
  Regions to be eroded.
- **RegionErosion** (output_object) ..................................... region(-array) \(\sim\) object
  Eroded regions.
- **GolayElement** (input_control) ...................................... string \(\sim\) string
  Structuring element from the Golay alphabet.
  Default value: ‘h’
- **Iterations** (input_control) ........................................... integer \(\sim\) integer
  Number of iterations.
  Default value: 1
  Suggested values: Iterations \(\in\) {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
  Typical range of values: 1 \(\leq\) Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Rotation** (input_control) ............................................. integer \(\sim\) integer
  Rotation of the Golay element. Depending on the element, not all rotations are valid.
  Default value: 0
  List of values: Rotation \(\in\) {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}
Complexity

Let $F$ be the area of an input region. Then the runtime complexity for one region is:

$$O(3 \cdot \sqrt{F})$$

Result

erosion_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system(‘no_object_result’,<RegionResult>)
  ```
- empty region:
  ```
  set_system(‘empty_region_result’,<RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, watersheds, class_ndim_norm

Possible Successors

Module

erosion_seq ( Region : RegionErosion : GolayElement, Iterations : )

Erode a region sequentially.

erosion_seq is obsolete and is only provided for reasons of backward compatibility.

erosion_seq computes the sequential erosion of the input region Region with the selected structuring element GolayElement from the Golay alphabet. This is done by executing the operator erosion_golay with all rotations of the structuring element Iterations times. The following structuring elements can be selected: 'l', 'd', 'c', 'f', 'h', 'k'.

Only the “foreground elements” (even rotation numbers) are used. The elements 'i' and 'e' result in unchanged output regions. The elements 'l', 'm' and 'f2' are identical for the foreground. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

Parameters

- **Region** (input_object)  
  Regions to be eroded.
- **RegionErosion** (output_object)  
  Eroded regions.
- **GolayElement** (input_control)  
  Structuring element from the Golay alphabet.  
  Default value: 'h'  
  List of values: GolayElement ∈ {'l', 'd', 'c', 'f', 'h', 'k'}
Iterations (input_control) ............................................................ integer \sim integer
Number of iterations.
Default value: 1
Suggested values: Iterations \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 20, 30, 40, 50\}
Typical range of values: 1 \leq \text{Iterations (lin)}
Minimum increment: 1
Recommended increment: 1

Complexity

Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[ O(\text{iterations} \cdot 20 \cdot \sqrt{F}) \] .

Result

erosion_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  \text{set_system}('no_object_result',<RegionResult>)
- empty region:
  \text{set_system}('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

dilation_seq, hit_or_miss_seq, thinning_seq

Module

fitting ( Region, StructElements : RegionFitted : : )

Perform a closing after an opening with multiple structuring elements.

fitting is obsolete and is only provided for reasons of backward compatibility.

fitting performs an opening and a closing successively on the input regions. The eight structuring elements normally used for this operation can be generated with the operator \text{gen_struct_elements}. However, other user-defined structuring elements can also be used. Let \( R \) be the input region(s) and let \( M_i \) denote the structuring elements. Furthermore, let \( P \) be the result of the opening and \( Q \) be the final result. Then the operator can be formalized as follows:

\[
P = \bigcup_{i=1}^{n} (R \circ M_i)
\]

\[
Q = \bigcap_{i=1}^{n} (P \bullet M_i)
\]
Regions larger than the structuring elements are preserved, while small gaps are closed.

Parameters

- **Region** (input_object) region(-array) → object
  Regions to be processed.
- **StructElements** (input_object) region(-array) → object
  Structuring elements.
- **RegionFitted** (output_object) region(-array) → object
  Fitted regions.

Result

fitting returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  ```python
  set_system('no_object_result', <RegionResult>)
  ```
- empty region:
  
  ```python
  set_system('empty_region_result', <RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- `gen_struct_elements`
- `gen_region_points`

Possible Successors

- `reduce_domain`
- `select_shape`
- `area_center`
- `connection`

Alternatives

- `opening`
- `closing`
- `connection`
- `select_shape`

Module

**gen_struct_elements** ( : StructElements : Type, Row, Column : )

Generate standard structuring elements.

**gen_struct_elements** is obsolete and is only provided for reasons of backward compatibility.

gen_struct_elements serves to generate eight structuring elements normally used in the operator fitting. The default value ‘noise’ of the parameter Type generates elements especially suited for the elimination of noise.
CHAPTER 17 LEGACY

Parameters

▷ StructElements (output_object) .............................................................. region(-array) ~ object
   Generated structuring elements.
▷ Type (input_control) ................................................................. string ~ string
   Type of structuring element to generate.
   Default value: 'noise'
   List of values: Type ∈ {‘noise’}
▷ Row (input_control) ................................................................. point.y ~ integer
   Row coordinate of the reference point.
   Default value: 1
   Suggested values: Row ∈ {0, 1, 10, 50, 100, 200, 300, 400}
   (lin)
▷ Column (input_control) ............................................................. point.x ~ integer
   Column coordinate of the reference point.
   Default value: 1
   Suggested values: Column ∈ {0, 1, 10, 50, 100, 200, 300, 400}
   (lin)

Result

gen_struct_elements returns 2 (H_MSG_TRUE) if all parameters are correct. Otherwise, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

golay_elements

Module

Foundation

---

golay_elements ( : StructElement1, StructElement2 : GolayElement,
                   Rotation, Row, Column : )

Generate the structuring elements of the Golay alphabet.

golay_elements is obsolete and is only provided for reasons of backward compatibility.

golay_elements generates the structuring elements from the Golay alphabet. The parameter GolayElement determines the name of the structuring element, while Rotation determines its rotation. The structuring elements are intended for use in hit_or_miss: In StructElement1 the structuring element for the foreground is returned, while in StructElement2 the structuring element for the background is returned. Row and Column determine the reference point of the structuring element.

The rotations are numbered from 0 to 15. This does not mean, however, that there are 16 different rotations: Even values denote rotations of the foreground elements, while odd values denote rotations of the background elements.

For golay_elements only even values are accepted, and determine the Golay element for StructElement1. The next larger odd value is used for StructElement2. There are no rotations for the Golay elements ‘h’ and ‘i’. Therefore, only the values 0 and 1 are possible as “rotations” (and hence only 0 for golay_elements). The element ‘e’ has only four possible rotations, and hence the rotation must be between 0 and 7 (for golay_elements the values 0, 2, 4, or 6 must be used).

The tables below show the elements of the Golay alphabet with all possible rotations. The characters used have the following meaning:

• Foreground pixel
- Background pixel
- Don’t care pixel

The names of the elements and their rotation numbers are displayed below the respective element. The elements with even number contain the foreground pixels, while the elements with odd numbers contain the background pixels.
\begin{itemize}
  \item \textbf{StructElement1} (output_object) \hspace{1cm} \text{region} \xrightarrow{\text{object}} \text{Structuring element for the foreground.}
  \item \textbf{StructElement2} (output_object) \hspace{1cm} \text{region} \xrightarrow{\text{object}} \text{Structuring element for the background.}
\end{itemize}
GolayElement (input_control)    string  ~  string
Name of the structuring element.
Default value: 'l'
List of values: GolayElement ∈ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

Rotation (input_control)    integer  ~  integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default value: 0
List of values: Rotation ∈ {0, 2, 4, 6, 8, 10, 12, 14}

Row (input_control)    integer  ~  integer
Row coordinate of the reference point.
Default value: 16
Suggested values: Row ∈ {0, 16, 32, 128, 256}
Typical range of values: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Column (input_control)    integer  ~  integer
Column coordinate of the reference point.
Default value: 16
Suggested values: Column ∈ {0, 16, 32, 128, 256}
Typical range of values: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Result
golay_elements returns 2 (H_MSG_TRUE) if all parameters are correct. Otherwise, an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

References

Module

hit_or_miss_golay ( Region : RegionHitMiss : GolayElement, Rotation : )

Hit-or-miss operation for regions using the Golay alphabet.

hit_or_miss_golay is obsolete and is only provided for reasons of backward compatibility.

hit_or_miss_golay performs the hit-or-miss-transformation for the input regions Region (using structuring elements from the Golay alphabet). First, an erosion with the foreground of the structuring element GolayElement is done on the input region Region. Then an erosion with the background of the structuring element GolayElement is performed on the complement of the input region. The intersection of the two resulting regions is the result RegionHitMiss of hit_or_miss_golay. The following structuring elements are available:
The rotation number \( \text{Rotation} \) determines which rotation of the element should be used. The hit-or-miss-transformation selects precisely the points for which the conditions given by the selected Golay element are fulfilled.

\[ \text{Attention} \]
Not all values of \( \text{Rotation} \) are valid for any Golay element.

\[ \text{Parameters} \]
- **Region** (input_object) \( \leadsto \text{region(-array)} \mapsto \text{object} \)
  Regions to be processed.
- **RegionHitMiss** (output_object) \( \leadsto \text{region(-array)} \mapsto \text{object} \)
  Result of the hit-or-miss operation.
- **GolayElement** (input_control) \( \leadsto \text{string} \)
  Structuring element from the Golay alphabet.
  Default value: `'h'`
  List of values: \( \text{GolayElement} \in \{ 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k' \} \)
- **Rotation** (input_control) \( \leadsto \text{integer} \)
  Rotation of the Golay element. Depending on the element, not all rotations are valid.
  Default value: 0
  List of values: \( \text{Rotation} \in \{ 0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15 \} \)

\[ \text{Complexity} \]
Let \( F \) be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \]

\[ \text{Result} \]
\( \text{hit_or_miss_golay} \) returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  \( \text{set_system}('\text{no_object_result}',<\text{RegionResult}>) \)
- empty region:
  \( \text{set_system}('\text{empty_region_result}',<\text{RegionResult}>) \)

Otherwise, an exception is raised.

\[ \text{Execution Information} \]

hit_or_miss_seq ( Region : RegionHitMiss : GolayElement : )

Hit-or-miss operation for regions using the Golay alphabet (sequential).
hit_or_miss_seq is obsolete and is only provided for reasons of backward compatibility.
hit_or_miss_golay performs the hit-or-miss-transformation for the input regions Region using all rotations of a structuring element from the Golay alphabet. The result of the operator is the union of all intermediate results of the respective rotations. The following structuring elements are available:
'I', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.
The Golay elements, together with all possible rotations, are described with the operator golay_elements.

Parameters

- Region (input_object) region(-array) ~ object
  Regions to be processed.
- RegionHitMiss (output_object) region(-array) ~ object
  Result of the hit-or-miss operation.
- GolayElement (input_control) string ~ string
  Structuring element from the Golay alphabet.
  Default value: 'h'
  List of values: GolayElement ∈ {I', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

Complexity

Let \( F \) be the area of an input region, and \( R \) be the number of rotations. Then the runtime complexity for one region is:

\[
O(R \cdot 6 \cdot \sqrt{F})
\]

Result

hit_or_miss_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors
threshold, region_growing, connection, union1, watersheds, class_ndim_norm

Module
Foundation
**morph_hat** (Region, StructElement : RegionMorphHat : :)

Compute the union of **bottom_hat** and **top_hat**.

**morph_hat** is obsolete and is only provided for reasons of backward compatibility.

**morph_hat** computes the union of the regions that are removed by an opening operation with the regions that are added by a closing operation. Hence this is the union of the results of **top_hat** and **bottom_hat**. The position of **StructElement** does not influence the result.

Structuring elements (**StructElement**) can be generated with operators such as **gen_circle**, **gen_rectangle1**, **gen_rectangle2**, **gen_ellipse**, **draw_region**, **gen_region_polygon**, **gen_region_points**, etc.

Attention

The individual regions are processed separately.

---

**Parameters**

- **Region** (input_object) .......................................................... region(-array) -> object
  Regions to be processed.

- **StructElement** (input_object) ..............................................region -> object
  Structuring element (position-invariant).

- **RegionMorphHat** (output_object) ......................................... region(-array) -> object
  Union of top hat and bottom hat.

---

**Example**

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
  cout << "Reproduction of 'dilation_circle ()'" << endl;
  cout << "First = original image " << endl;
  cout << "Red = after segmentation " << endl;
  cout << "Blue = after erosion " << endl;

  HByteImage img("monkey");
  HWindow w;

  HRegion circ = HRegion::GenCircle (10, 10, 1.5);
  HRegionArray regs = (img >= 128).Connection();
  HRegionArray tophat = regs.TopHat (circ);
  HRegionArray bothat = regs.BottomHat (circ);
  HRegionArray unionX = tophat.Union2 (bothat);

  img.Display (w); w.Click ();
  w.SetColor ("red"); regs.Display (w); w.Click ();
  w.SetColor ("blue"); tophat.Display (w); w.Click ();
  w.SetColor ("green"); bothat.Display (w); w.Click ();
  w.SetColor ("white"); unionX.Display (w); w.Click ();

  return(0);
}
```

**Result**

**morph_hat** returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:
Compute the morphological skeleton of a region.

morph_skeleton is obsolete and is only provided for reasons of backward compatibility.

morph_skeleton computes the skeleton of the input regions (Region) using morphological transformations. The computation yields a disconnected skeleton (gaps in the diagonals) having a width of one or two pixels. The calculation uses the Golay element ‘h’, i.e., an 8-neighborhood. This is equivalent to the maximum-norm.

Parameters

- **Region** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . object
  Regions to be processed.

- **RegionSkeleton** (output_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . object
  Resulting morphological skeleton.

Result

morph_skeleton returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Possible Predecessors

-threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

Possible Successors

-reduce_domain, select_shape, area_center, connection

Alternatives

-top_hat, bottom_hat, union2

Alternatives:
skeleton

Module

| morph_skiz ( Region : RegionSkiz : Iterations1, Iterations2 : ) |

**Thinning of a region.**

**morph_skiz** is obsolete and is only provided for reasons of backward compatibility.

morph_skiz first performs a sequential thinning (**thinning_seq**) of the input region with the element ’l’ of the Golay alphabet. The number of iterations is determined by the parameter **Iterations1**. Then a sequential thinning of the resulting region with the element ’e’ of the Golay alphabet is carried out. The number of iterations for this step is determined by the parameter **Iterations2**. The skiz operation serves to compute a kind of skeleton of the input regions, and to prune the branches of the resulting skeleton. If the skiz operation is applied to the complement of the region, the region and the resulting skeleton are separated.

If very large values or ’maximal’ are passed for **Iterations1** or **Iterations2**, the processing stops if no more changes occur.

**Parameters**

- **Region** (input_object) ......................................... region(-array) ↦ object
  Regions to be thinned.
- **RegionSkiz** (output_object) ................................. region(-array) ↦ object
  Result of the skiz operator.
- **Iterations1** (input_control) .............................. integer ↦ integer / string
  Number of iterations for the sequential thinning with the element ’l’ of the Golay alphabet.
  Default value: 100
  Suggested values: Iterations1 ∈ [’maximal’, 0, 1, 2, 3, 5, 7, 10, 15, 20, 30, 40, 50, 70, 100, 150, 200, 300, 400]
  Typical range of values: 0 ≤ Iterations1 (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Iterations2** (input_control) .............................. integer ↦ integer / string
  Number of iterations for the sequential thinning with the element ’e’ of the Golay alphabet.
  Default value: 1
  Suggested values: Iterations2 ∈ [’maximal’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50]
  Typical range of values: 0 ≤ Iterations2 (lin)
  Minimum increment: 1
  Recommended increment: 1

**Complexity**

Let $F$ be the area of the input region. Then the runtime complexity for one region is

$$O((\text{Iterations1} + \text{Iterations2}) \cdot 3 \cdot \sqrt{F}) .$$

**Result**

**morph_skiz** returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system(‘no_object_result’,<RegionResult>)
  ```
• empty region:
  
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

```
opening_golay ( Region : RegionOpening : GolayElement, Rotation : )
```

**open a region with an element from the Golay alphabet.**

**opening_golay** is obsolete and is only provided for reasons of backward compatibility.

opening_golay is defined as a Minkowski subtraction followed by a Minkowski addition. First the Minkowski subtraction of the input region (Region) with the structuring element from the Golay alphabet defined by GolayElement and Rotation is computed. Then the Minkowski addition of the result and the structuring element rotated by 180° is performed.

The following structuring elements are available:

' l', ' m', ' d', ' c', ' e', ' i', ' f ', ' f2', ' h', ' k'.

The rotation number Rotation determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator golay_elements.

opening_golay serves to eliminate regions smaller than the structuring element, and to smooth regions’ boundaries.

---

**Attention**

Not all values of Rotation are valid for any Golay element. For some of the values of Rotation, the resulting regions are identical to the input regions.

---

**Parameters**

- **Region** (input_object) 
  
  Region(-array) \( \rightsquigarrow \) object
  
  Regions to be opened.

- **RegionOpening** (output_object) 
  
  Region(-array) \( \rightsquigarrow \) object
  
  Opened regions.

- **GolayElement** (input_control) 
  
  Structuring element from the Golay alphabet.
  
  Default value: 'h'
  
  List of values: GolayElement \( \in \) \{'l', 'm', 'd', 'c', 'e', 'i', 'f ', 'f2', 'h', 'k'\}
CHAPTER 17 LEGACY

Rotation (input_control) ................................. integer \sim integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default value: 0
List of values: Rotation \in \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}

Complexity
Let $F$ be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \]

Result
opening_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors
threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

Possible Successors
reduce_domain, select_shape, area_center, connection

Alternatives
opening_seg, opening

See also
erosion_golay, dilation_golay, closing_golay, hit_or_miss_golay, thinning_golay, thickening_golay, golay_elements

Module

opening_seg ( Region, StructElement : RegionOpening : : )

Separate overlapping regions.

opening_seg is obsolete and is only provided for reasons of backward compatibility.

The opening_seg operation is defined as a sequence of the following operators: erosion1, connection and dilation1 (see example). Only one iteration is done in erosion1 and dilation1.

opening_seg serves to separate overlapping regions whose area of overlap is smaller than StructElement. It should be noted that the resulting regions can overlap without actually merging (see expand_region).

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.
17.9. MORPHOLOGY

---

**Parameters**

- **Region** (input_object) .................................................. region(-array) $\sim$ object
  Regions to be opened.
- **StructElement** (input_object) ...................................... region $\sim$ object
  Structuring element (position-invariant).
- **RegionOpening** (output_object) ...................................... region-array $\sim$ object
  Opened regions.

**Example**

* Simulation of opening_seg

* opening_seg(Region,StructElement,RegionOpening):
  
  erosion1(Region,StructElement,H1,1)
  connection(H1,H2)
  dilation1(H2,StructElement,RegionOpening,1)

**Complexity**

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \sqrt{\sqrt{F_1}}) .$$

**Result**

opening_seg returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  set_system(’no_object_result’,<RegionResult>)

- empty region:
  
  set_system(’empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Predecessors**

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

**Possible Successors**

expand_region, reduce_domain, select_shape, area_center, connection

**Alternatives**

erosion1, connection, dilation1

**Module**

---

**thickening** ( Region, StructElement1, StructElement2 : RegionThick : Row, Column, Iterations : )

Add the result of a hit-or-miss operation to a region.
thickening is obsolete and is only provided for reasons of backward compatibility.

*thickening* performs a thickening of the input regions using morphological operations. The operator first applies a hit-or-miss-transformation to *Region* (cf. *hit_or_miss*), and then adds the detected points to the input region. The parameter *Iterations* determines the number of iterations performed.

For the choice of the structuring elements *StructElement1* and *StructElement2*, as well as for *Row* and *Column*, the same restrictions described under *hit_or_miss* apply.

The structuring elements (*StructElement1* and *StructElement2*) can be generated by calling *golay_elements*, for example.

---

**Attention**

If the reference point is contained in *StructElement1* the input region remains unchanged.

---

### Parameters

- **Region** *(input_object)* .......................... region(-array) → *object*
  Regions to be processed.
- **StructElement1** *(input_object)* .................. region → *object*
  Structuring element for the foreground.
- **StructElement2** *(input_object)* .................. region → *object*
  Structuring element for the background.
- **RegionThick** *(output_object)* ................. region(-array) → *object*
  Result of the thickening operator.
- **Row** *(input_control)* ............................ point.y → *integer*
  Row coordinate of the reference point.
  Default value: 16
  Suggested values: Row ∈ {0, 2, 4, 8, 16, 32, 128}
  Typical range of values: 0 ≤ Row ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Column** *(input_control)* ........................ point.x → *integer*
  Column coordinate of the reference point.
  Default value: 16
  Suggested values: Column ∈ {0, 2, 4, 8, 16, 32, 128}
  Typical range of values: 0 ≤ Column ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Iterations** *(input_control)* ...................... integer → *integer*
  Number of iterations.
  Default value: 1
  Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50, 70, 100, 200, 400}
  Typical range of values: 1 ≤ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

---

### Complexity

Let $F$ be the area of an input region, $F_1$ the area of the structuring element 1, and $F_2$ the area of the structuring element 2. Then the runtime complexity for one object is:

$$O\left(\text{Iterations} \cdot \sqrt{F} \cdot \left(\sqrt{F_1} + \sqrt{F_2}\right)\right).$$

---

### Result

*thickening* returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system(’no_object_result’,<RegionResult>)
  ```
- empty region:
  ```
  set_system(’empty_region_result’,<RegionResult>)
  ```
Otherwise, an exception is raised.

---

### `thickening_golay` (Region : RegionThick : GolayElement, Rotation : )

*Add the result of a hit-or-miss operation to a region (using a Golay structuring element).*

**thickening_golay** is obsolete and is only provided for reasons of backward compatibility.

`thickening_golay` performs a thickening of the input regions using morphological operations and structuring elements from the Golay alphabet. The operator first applies a hit-or-miss-transformation to `Region` (cf. `hit_or_miss_golay`), and then adds the detected points to the input region. The following structuring elements are available:

- 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number `Rotation` determines which rotation of the element should be used. The Golay elements, together with all possible rotations, are described with the operator `golay_elements`.

---

**Attention**

Not all values of `Rotation` are valid for any Golay element.

---

**Parameters**

- **Region** (input_object) .................................................. region(-array) \(\rightarrow\) object
  Regions to be processed.
- **RegionThick** (output_object) ........................................... region(-array) \(\rightarrow\) object
  Result of the thickening operator.
- **GolayElement** (input_control) .......................................... string \(\rightarrow\) string
  Structuring element from the Golay alphabet.
  **Default value:** 'h'
  **List of values:** GolayElement \(\in\) 
  \{'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'\}
- **Rotation** (input_control) ............................................... integer \(\rightarrow\) integer
  Rotation of the Golay element. Depending on the element, not all rotations are valid.
  **Default value:** 0
  **List of values:** Rotation \(\in\) \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}

---

**Complexity**

Let \(F\) be the area of an input region. Then the runtime complexity for one region is:

\[ O(6 \cdot \sqrt{F}) \]
thickening_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or
no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

erosion_golay, hit_or_miss_golay

Module
Foundation

thickening_seq ( Region : RegionThick : GolayElement,
   Iterations : )

Add the result of a hit-or-miss operation to a region (sequential).

thickening_seq is obsolete and is only provided for reasons of backward compatibility.

thickening_seq calculates the sequential thickening of the input regions with a structuring element from the
Golay alphabet (GolayElement). To do so, thickening_seq calls the operator thickening_golay
with all possible rotations of the structuring element Iterations times. The following structuring elements are
available:
'i', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The Golay elements, together with all possible rotations, are described with the operator golay_elements. For
all elements of the Golay alphabet, except for 'c', the foreground and background masks are exchanged in order to
have an effect on them on the outer boundary of the region. The element 'c' can be used to generate the convex
hull of the input region if enough iterations are performed.

Parameters

Region (input_object) region(-array) object
Regions to be processed.

RegionThick (output_object) region(-array) object
Result of the thickening operator.

GolayElement (input_control) string
Structuring element from the Golay alphabet.

Default value: 'h'
List of values: GolayElement ∈ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

Iterations (input_control) integer
Number of iterations.

Default value: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50, 70, 100, 200}
Typical range of values: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1
Complexity

Let $F$ be the area of an input region. Then the runtime complexity for one region is:

$$O(\text{Iterations} \cdot 6 \cdot \sqrt{F})$$.

Result

thickening_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

erosion_golay, thinning_seq

Module

thinning ( Region, StructElement1, StructElement2 : RegionThin : Row, Column, Iterations : )

Remove the result of a hit-or-miss operation from a region.

thinning is obsolete and is only provided for reasons of backward compatibility.

thinning performs a thinning of the input regions using morphological operations. The operator first applies a hit-or-miss-transformation to Region (cf. hit_or_miss), and then removes the detected points from the input region. The parameter Iterations determines the number of iterations performed.

For the choice of the structuring elements StructElement1 and StructElement2, as well as for Row and Column, the same restrictions described under hit_or_miss apply.

Structuring elements (StructElement1, StructElement2) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- **Region** (input_object) region(-array) \(\sim\) object
  - Regions to be processed.
- **StructElement1** (input_object) region \(\sim\) object
  - Structuring element for the foreground.
- **StructElement2** (input_object) region \(\sim\) object
  - Structuring element for the background.
- **RegionThin** (output_object) region(-array) \(\sim\) object
  - Result of the thinning operator.
\( \text{Row} \) (input_control) \( \ldots \) \( \ldots \) point.y \( \sim \) integer
Row coordinate of the reference point.
**Default value**: 0
**Typical range of values**: \( 0 \leq \text{Row} \leq 511 \) (lin)
**Minimum increment**: 1
**Recommended increment**: 1

\( \text{Column} \) (input_control) \( \ldots \) \( \ldots \) point.x \( \sim \) integer
Column coordinate of the reference point.

Foundation

HALCON 20.11.0.0
thinning_seq ( Region : RegionThin : GolayElement, Iterations : )

Remove the result of a hit-or-miss operation from a region (sequential).

thinning_seq is obsolete and is only provided for reasons of backward compatibility.

thinning_seq calculates the sequential thinning of the input regions with a structuring element from the Golay alphabet (GolayElement). To do so, thinning_seq calls the operator thinning_golay with all possible rotations of the structuring element Iterations times. If Iterations is chosen large enough, the operator calculates the skeleton of a region if the structuring elements 'l' or 'm' are used. For the element 'c' the background and foreground are exchanged in order to have an effect on the interior boundary of a region. If a very large value or 'maximal' is passed for Iterations the iteration stops if no more changes occur. The following structuring elements are available:

'\text{l}' Skeleton, similar to skeleton. This structuring element is also used in morph_skiz.

'm' A skeleton with many “hairs” and multiple (parallel) branches.

'd' A skeleton without multiple branches, but with many gaps, similar to morph_skeleton.

'c' Uniform erosion of the region.

'e' One pixel wide lines are shortened. This structuring element is also used in morph_skiz.

'I' Isolated points are removed. (Only Iterations = 1 is useful.)

'I' Y-junctions are eliminated. (Only Iterations = 1 is useful.)

'F2' One pixel long branches and corners are removed. (Only Iterations = 1 is useful.)

'h' A kind of inner boundary, which, however, is thicker than the result of boundary, is generated. (Only Iterations = 1 is useful.)

'k' Junction points are eliminated, but also new ones are generated.

The Golay elements, together with all possible rotations, are described with the operator golay_elements.

--- Parameters ---

- **Region** (input_object) \(\Rightarrow\) region(-array) \(\sim\) object
  Regions to be processed.

- **RegionThin** (output_object) \(\Rightarrow\) region(-array) \(\sim\) object
  Result of the thinning operator.

- **GolayElement** (input_control) \(\Rightarrow\) string
  Structuring element from the Golay alphabet.
  Default value: 'l'
  List of values: 
  \[\{ 'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k' \}\]

- **Iterations** (input_control) \(\Rightarrow\) integer
  Number of iterations. For 'f', 'f2', 'h' and 'i' the only useful value is 1.
  Default value: 20
  Suggested values: 
  \[\{ 'maximal', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 40, 50, 70, 100, 150, 200 \}\]
  Typical range of values: \(1 \leq \text{Iterations} \leq \text{lin}\)
  Minimum increment: 1
  Recommended increment: 1

--- Complexity ---

Let \(F\) be the area of an input region. Then the runtime complexity for one region is:

\[
O(\text{Iterations} \cdot 6 \cdot \sqrt{F})
\]

--- Result ---

thinning_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  ```
  set_system('no_object_result',<RegionResult>)
  ```
• empty region:
  
  ```set_system('empty_region_result',<RegionResult>)```

Otherwise, an exception is raised.

---

## 17.10 OCR

### close_ocr ( : : OcrHandle : )

**Deallocation of the memory of an OCR classifier.**

`close_ocr` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `close_ocr` deallocates the memory of the classifier having the number `OcrHandle`. Hereby all corresponding data will be deleted. However, if necessary, they can be saved in advance using the operator `write_ocr`. The number `OcrHandle` will be invalid after the call; but later the system can use it again for new classifiers.

---

### Attention

All data of the classifier will be deleted in main memory (not on the hard disk).

---

### Parameters

- `OcrHandle` (input_control) .......................... `ocr_box`  \rightarrow  `handle`
  ID of the OCR classifier to be deleted.

### Result

If the parameter `OcrHandle` is valid, the operator `close_ocr` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `OcrHandle`
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**
- `write_ocr_trainf`

**Possible Successors**
- `read_ocr`

**Module**
- OCR/OCV

```
create_ocr_class_box ( : : WidthPattern, HeightPattern, Interpolation, Features, Character : OcrHandle )
```

Create a new OCR-classifier.

The operator `create_ocr_class_box` creates a new OCR classifier. For a description of this classifier see operator `learn_class_box`. This classifier must then be trained with the help of the operators `traind_ocr_class_box` or `trainf_ocr_class_box`

The parameters `WidthPattern` and `HeightPattern` indicate the size of the input-layer of the network. This size is used for the features 'projection_horizontal', 'projection_vertical', 'pixel', 'pixel_invar', and 'pixel_binary' to transform the character to a standard size. The bigger the standard size is, the more characters can be distinguished. Hereby the amount of time necessary for the training (as well as the number of training random samples) and the time necessary for the recognition, however, will increase as well. The parameter `Interpolation` indicates the interpolation mode concerning the adaptation of characters in the image to the network. For more detailed information on this parameter see also `affine_trans_image`. The value 0 results in the same interpolation as 'nearest_neighbor' in `affine_trans_image`, i.e., no interpolation is performed. For 1, the same behavior as 'constant' in `affine_trans_image` is obtained, i.e., equally weighted interpolation between adjacent pixels is used. Finally, 2 results in the same interpolation as 'weighted', i.e., Gaussian interpolation between adjacent pixels is used. The parameter `Interpolation` must be chosen such that no aliasing occurs when the character is scaled to the standard size. Typically, this means that `Interpolation` should be set to 1, except in cases where the characters are scaled down by a large amount, in which case `Interpolation` = 2 should be chosen. `Interpolation` = 0 should only be chosen if the characters will not be scaled.

The parameter `Character` determines all the characters which have to be recognized. Normally the transmitted strings consist of one character (e.g. alphabet). But also strings of any length can be learned. The number of distinguishable characters (number of strings in `Character`) is limited to 2048.

The parameter `Features` helps to chose additional features besides gray values in order to recognize characters. The following features are available:

- 'default' 'ratio' and 'pixel_invar' are selected.
- 'ratio' Ratio of the character.
- 'width' Width of the character (not invariant to scaling).
- 'height' Height of the character (not invariant to scaling).
- 'zoom_factor' Difference in size between the current character and the values of `WidthPattern` and `HeightPattern` (not invariant to scaling).
- 'foreground' Relative number of pixels in the foreground.
- 'foreground_grid_9' Relative number of foreground pixels in a $3 \times 3$ grid within the surrounding rectangle of the character.
- 'foreground_grid_16' Relative number of foreground pixels in a $4 \times 4$ grid within the surrounding rectangle of the character.
- 'anisometry' Form feature anisometry.
- 'compactness' Form feature compactness.
- 'convexity' Form feature convexity.
'moments_region_2nd_invar'  Normed 2nd geometric moments of the region. See also 
moments_region_2nd_invar.

'moments_region_2nd_rel_invar'  Normed 2nd relative geometric moments of the region. See also 
moments_region_2nd_rel_invar.

'moments_region_3rd_invar'  Normed 3rd geometric moments of the region. See also 
moments_region_3rd_invar.

'moments_central'  Normed central geometric moments of the region. See also moments_region_central.

'phi'  Sine and cosine of the orientation (angle) of the character.

'num_connect'  Number of connecting components.

'num_holes'  Number of holes.

'projection_horizontal'  Horizontal projection of the gray values.

'projection_horizontal_invar'  Horizontal projection of the gray values with are automatically scaled to maximum range.

'projection_vertical'  Vertical projection of the gray values.

'projection_vertical_invar'  Vertical projection of the gray values with are automatically scaled to maximum range.

'cooc'  Values of the binary cooccurrence matrix.

'moments_gray_plane'  Normed gray value moments and the angles of the gray value level.

'num_runs'  Number of chords in the region normed to the height.

'chord_histo'  Frequency of the chords per row (not scale-invariant).

'pixel'  Gray value of the character.

'pixel_invar'  Gray values of the character with automatic maximal scaling of the gray values.

'pixel_binary'  Region of the character as a binary image zoomed to a size of WidthPattern × HeightPattern.

'gradient_8dir'  Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5 × 5 grid are extracted from each channel. These samples are used as features.

--- Parameters ---

▷ WidthPattern (input_control) ................................. integer  ⇆ integer
Width of the input layer of the network.

Default value: 8
Suggested values: WidthPattern ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Typical range of values: 1 ≤ WidthPattern ≤ 100

▷ HeightPattern (input_control) ................................. integer  ⇆ integer
Height of the input layer of the network.

Default value: 10
Suggested values: HeightPattern ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Typical range of values: 1 ≤ HeightPattern ≤ 100

▷ Interpolation (input_control) ................................. integer  ⇆ integer
Interpolation mode concerning scaling of characters.

Default value: 1
List of values: Interpolation ∈ {0, 1, 2}

▷ Features (input_control) ................................. string(-array)  ⇆ string
Additional features.

Default value: 'default'
Character (input_control) ........................................... string-array  \* string
All characters of a set.
Default value: ['a', 'b', 'c']

OcrHandle (output_control) ........................................ ocr_box  \* handle
ID of the created OCR classifier.

If the parameters are correct, the operator create_ocr_class_box returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---------- Result

---------- Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

OCR/OCV

create_text_model ( : : : TextModel )

Create a text model.

create_text_model is obsolete and is only provided for reasons of backward compatibility. New applications should use create_text_model_reader instead.

create_text_model creates a new TextModel which describes the text to be segmented by find_text. Set and query Parameters of TextModel via set_text_model_param and get_text_model_param.

Calls of create_text_model are equivalent to (and should be replaced by) calls of create_text_model_reader with Mode set to 'manual'.

---------- Parameters

- TextModel (output_control) ........................................... text_model  \* handle
New text model.

---------- Result

create_text_model returns the value 2 (H_MSG_TRUE).

---------- Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```
Module OCR/OCV
```

```halcon
deserialize_ocr ( : : SerializedItemHandle : OcrHandle )
```

Deserializes a serialized OCR classifier.

deserialize_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

deserialize_ocr deserializes an OCR classifier, that was serialized by serialize_ocr (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OcrHandle.

```
Parameters
```

- SerializedItemHandle (input_control) ............................................ serialized_item ~ handle
  Handle of the serialized item.
- OcrHandle (output_control) ...................................................... ocr_box ~ handle
  ID of the OCR classifier.

```
Result
```

If the parameters are valid, the operator deserialize_ocr returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

```
Execution Information
```

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

```
Module
```

OCR/OCV

```
do_ocr_multi ( Character, Image : : OcrHandle : Class, Confidence )
```

Classify characters.

do_ocr_multi is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator do_ocr_multi assigns a class to every Character (character). For gray value features the gray values from the surrounding rectangles of the regions are used. The gray values will be taken from the parameter Image. For each character the corresponding class will be returned in Class and a confidence value will be returned in Confidence. The confidence value indicates the similarity between the input pattern and the assigned character.
**Parameters**

- **Character** (input_object) ... region(-array) \(\sim\) object
  Characters to be recognized.

- **Image** (input_object) ... singlechannelimage \(\sim\) object : byte / uint2
  Gray values for the characters.

- **OcrHandle** (input_control) ... ocr_box \(\sim\) handle
  ID of the OCR classifier.

- **Class** (output_control) ... string(-array) \(\sim\) string
  Class (name) of the characters.

  **Number of elements:** Class == Character

- **Confidence** (output_control) ... real(-array) \(\sim\) real
  Confidence values of the characters.

  **Number of elements:** Confidence == Character

**Result**

If the input parameters are correct, the operator `do_ocr_single` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Possible Predecessors**

**Module**

OCR/OCV

**do_ocr_single** ( Character, Image : : OcrHandle : Classes, Confidences )

Classify one character.

`do_ocr_single` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `do_ocr_single` assigns classes to the **Character** (characters). For gray value features gray values of the surrounding rectangles of the regions will be used. The gray values will be taken from the parameter **Image**. For each character the two classes with the highest confidences will be returned in **Classes**. The corresponding confidences will be returned in **Confidences**. The confidence value indicates the similarity between the input pattern and the assigned character.

**Parameters**

- **Character** (input_object) ... region \(\sim\) object
  Character to be recognized.

- **Image** (input_object) ... singlechannelimage \(\sim\) object : byte / uint2
  Gray values of the characters.

- **OcrHandle** (input_control) ... ocr_box \(\sim\) handle
  ID of the OCR classifier.

- **Classes** (output_control) ... string-array \(\sim\) string
  Classes (names) of the characters.

  **Number of elements:** 2
Confidences (output_control) .................................................. real-array \rightarrow real
Confidence values of the characters.
Number of elements: 2

Result

If the input parameters are correct, the operator do_ocr_single returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

OCR/OCV

info_ocr_class_box ( : : OcrHandle : WidthPattern, HeightPattern, Interpolation, WidthMaxChar, HeightMaxChar, Features, Characters )

Get information about an OCR classifier.

info_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator info_ocr_class_box returns some information about an OCR classifier. The parameters are equivalent to those of create_ocr_class_box. The parameters WidthMaxChar and HeightMaxChar indicate the extension of the largest trained character. These values can be used to control the segmentation.

Parameters

• OcrHandle (input_control) .................................................. ocr_box \rightarrow handle
ID of the OCR classifier.
• WidthPattern (output_control) .......................................... integer \rightarrow integer
Width of the scaled characters.
• HeightPattern (output_control) .......................................... integer \rightarrow integer
Height of the scaled characters.
• Interpolation (output_control) .......................................... integer \rightarrow integer
Interpolation mode for scaling the characters.
• WidthMaxChar (output_control) ........................................ integer \rightarrow integer
Width of the largest trained character.
• HeightMaxChar (output_control) ........................................ integer \rightarrow integer
Height of the largest trained character.
• Features (output_control) ............................................... string-array \rightarrow string
Used features.
• Characters (output_control) ............................................. string-array \rightarrow string
All characters of the set.

Result

The operator info_ocr_class_box always returns 2 (H_MSG_TRUE).

Execution Information
Multithreading type: reentrant (runs in parallel with non-exclusive operators).
Multithreading scope: global (may be called from any thread).
Processed without parallelization.

**ocr_change_char** ( : : OcrHandle, Character : )

Define a new conversion table for the characters.

*ocr_change_char* is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator **ocr_change_char** establishes a new look-up table for the characters. Hereby the number of strings of **Character** must be the same as of the classifier **OcrHandle**. In order to enlarge the font, the operator **ocr_change_char** may be used as follows: More characters than actually needed will be indicated when creating a network using (**create_ocr_class_box**). The last \( n \) characters will not be used so far. If more characters are needed at a later stage, these unused characters will be allocated and then trained with the help of the operator **ocr_change_char**.

---

Parameters

- **OcrHandle** (input_control) ...................................................... ocr_box \( \rightarrow \) handle
  ID of the OCR-network to be changed.
- **Character** (input_control) ..................................................... string-array \( \rightarrow \) string
  New assign of characters.
  Default value: ['a','b','c']

---

Result

If the number of characters in **Character** is identical with the number of the characters of the network, the operator **ocr_change_char** returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **OcrHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

HALCON/HDevelop Reference Manual, 2020-11-10
**ocr_get_features** ( Character : : OcrHandle : FeatureVector )

Access the features which correspond to a character.

**ocr_get_features** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator **ocr_get_features** calculates the features for the given **Character**. The type and number of features is determined by the classifier **OcrHandle.FeatureVector** contains the same values which are used inside operators like **traind_ocr_class_box** or **trainf_ocr_class_box**.

---

**Parameters**

- **Character** (input_object) ........................................... singlechannelimage `~ object : byte / uint2 Characters to be trained.
- **OcrHandle** (input_control) ........................................... ocr_box `~ handle ID of the desired OCR-classifier.
- **FeatureVector** (output_control) ........................................... real-array `~ real Feature vector.

---

**Result**

If the parameters are correct, the operator **ocr_get_features** returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

---

**read_ocr** ( : : FileName : OcrHandle )

Read an OCR classifier from a file.

**read_ocr** is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator **read_ocr** reads an OCR classifier from a file **FileName**. This file will hereby be searched in the directory ($HALCONROOT/ocr/) as well as in the currently used directory. If too many classifiers have been loaded, an error message will be displayed.

---

**Parameters**

- **FileName** (input_control) ........................................... filename.read `~ string Name of the OCR classifier file.  
  **Default value:** 'testnet'
  **File extension:** .obc,.fnt
- **OcrHandle** (output_control) ........................................... ocr_box `~ handle ID of the read OCR classifier.

---

**Result**

If the indicated file is available and the format is correct, the operator **read_ocr** returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

---

**Execution Information**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module
OCR/OCV

```
serialize_ocr ( : : OcrHandle : SerializedItemHandle )
```

Serialize an OCR classifier.

`serialize_ocr` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

`serialize_ocr` serializes an OCR classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ocr` is converted to a serialized item. The OCR classifier is defined by the handle `OcrHandle`. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr`.

Parameters

- **OcrHandle** (input_control) — handle ID of the OCR classifier.
- **SerializedItemHandle** (output_control) — handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module
OCR/OCV

```
testd_ocr_class_box ( Character, Image : : OcrHandle, Class : Confidence )
```

Test an OCR classifier.
The operator `testd_ocr_class_box` tests the confidence with which a character belongs to a given class. Any number of regions of an image can be passed. For each character (region) in the `Character` the corresponding name (class) `Class` must be specified. The gray values are passed in `Image`. When the operator has finished the parameter `Confidence` provides information about how sure a character belongs to the (arbitrary chosen) class.

### Parameters

- **Character** (input_object) : region(-array) → object
  Characters to be tested.
- **Image** (input_object) : singlechannelimage → object : byte / uint2
  Gray values for the characters.
- **OcrHandle** (input_control) : ocr_box → handle
  ID of the desired OCR-classifier.
- **Class** (input_control) : string(-array) → string
  Class (name) of the characters.
  **Default value:** 'a'
- **Confidence** (output_control) : real(-array) → real
  Confidence for the character to belong to the class.

### Result

If the parameters are correct, the operator `testd_ocr_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

`read_ocr`, `trainf_ocr_class_box`, `traind_ocr_class_box`

### Module

**OCR/OCV**

The operator `traind_ocr_class_box` trains the classifier directly via the input of regions in an image. Any number of regions of an image can be passed. For each character (region) in the `Character` the corresponding name (class) `Class` must be specified. The gray values are passed in `Image`. When the procedure has finished the parameter `AvgConfidence` provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly).

### Parameters

- **Character** (input_object) : region(-array) → object
  Characters to be trained.
- **Image** (input_object) : singlechannelimage → object : byte / uint2
  Gray values for the characters.
- **OcrHandle** (input_control) : ocr_box → handle
  ID of the desired OCR-classifier.

- **Class** (input_control) : AvgConfidence
  Class (name) of the characters.
  **Default value:** 'a'

### Possible Predecessors

`read_ocr`, `trainf_ocr_class_box`, `traind_ocr_class_box`

### Module

**OCR/OCV**

The operator `traind_ocr_class_box` trains the classifier directly via the input of regions in an image. Any number of regions of an image can be passed. For each character (region) in the `Character` the corresponding name (class) `Class` must be specified. The gray values are passed in `Image`. When the procedure has finished the parameter `AvgConfidence` provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly).
Class (input_control) ................................. string(-array)  \sim string
Class (name) of the characters.

Default value: 'a'

AvgConfidence (output_control) ............................... real  \sim real
Average confidence during a re-classification of the trained characters.

Result

If the parameters are correct, the operator traind_ocr_class_box returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OcrHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Successors

write_ocr, do_ocr_multi, do_ocr_single

Alternatives

trainf_ocr_class_box

Module

OCR/OCV

trainf_ocr_class_box ( : : OcrHandle, TrainingFile : AvgConfidence )

Train an OCR classifier with the help of a training file.

trainf_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator trainf_ocr_class_box trains the classifier OcrHandle via the indicated training files. Any number of files can be indicated. The parameter AvgConfidence provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly). Please, note that training characters that have no corresponding class in the classifier OcrHandle are discarded.

Attention

The names of the characters in the file must fit the network.

Parameters

- OcrHandle (input_control) ............................................. ocr_box  \sim handle
ID of the desired OCR-network.

- TrainingFile (input_control) ................................. filename.read(-array)  \sim string
Names of the training files.

Default value: 'train_ocr'

File extension: .trf, .otr

- AvgConfidence (output_control) ............................... real  \sim real
Average confidence during a re-classification of the trained characters.
Result

If the file name is correct and the data fit the network, the operator `trainf_ocr_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OcrHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- `create_ocr_class_box`, `read_ocr`

Possible Successors

- `traind_ocr_class_box`, `write_ocr`, `do_ocr_multi`, `do_ocr_single`

Alternatives

- `traind_ocr_class_box` Module

OCR/OCV

```write_ocr ( : : OcrHandle, FileName : )
```

Writing an OCR classifier into a file.

`write_ocr` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `write_ocr` writes the OCR classifier `OcrHandle` into the file `FileName`. Since the data of the classifier will be lost when the program is finished, they have to be stored after the training if the user wants to use them again at a later execution of the program. The data can then be read with the help of the operator `read_ocr`. The extension will be added automatically to the parameter `FileName`.

Attention

The output file `FileName` must be given without extension.

Parameters

- **OcrHandle** (input_control) ... ID of the OCR classifier.
- **FileName** (input_control) ... Name of the file for the OCR classifier (without extension).
  - Default value: 'my_ocr'
  - File extension: .obc

Result

If the parameter `OcrHandle` is valid and the indicated file can be written, the operator `write_ocr` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module
OCR/OCV

17.11 Regions

get_region_chain ( Region : : : Row, Column, Chain )

Contour of an object as chain code.

get_region_chain is obsolete and is only provided for reasons of backward compatibility.

The operator get_region_chain returns the contour of a region. A contour is a series of pixels describing the outline of the region. The contour "lies on" the region. It starts at the smallest line number; in that line at the pixel with the largest column index. The rotation occurs clockwise. Holes of the region are ignored. The direction code (chain code) is defined as follows:

```
3 2 1
4 * 0
5 6 7
```

The operator get_region_chain returns the code in the form of a tuple. In case of an empty region the parameters Row and Column are zero and Chain is the empty tuple.

Holes of the region are ignored. Only one region may be passed, and it must have exactly one connection component.

Parameters

- **Region** (input_object) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ..

Result

The operator get_region_chain normally returns the value 2 (H_MSG_TRUE). If more than one connection component is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator set_system(‘no_object_result’,<Result>). The behavior in case of empty region (the region is the empty set) is set via the operator set_system(‘empty_region_result’,<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```
hamming_change_region ( InputRegion : OutputRegion : Width, Height,
Distance : )
```

Generate a region having a given Hamming distance.

**hamming_change_region** is obsolete and is only provided for reasons of backward compatibility.

**hamming_change_region** changes the region in the left upper part of the image given by **Width** and **Height** such that the resulting regions have a Hamming distance of **Distance** to the input regions. This is done by adding or removing **Distance** points from the input region.

**Attention**
If **Width** and **Height** are chosen too large the resulting region requires a lot of memory.

**Parameters**

- **InputRegion** (input_object) region(-array) → object
  Region to be modified.
- **OutputRegion** (output_object) region(-array) → object
  Regions having the required Hamming distance.
- **Width** (input_control) extent.x → integer
  Width of the region to be changed.
  Default value: 100
  Suggested values: **Width** ∈ \{64, 128, 256, 512\}
  Typical range of values: 1 ≤ **Width** ≤ 512 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: **Width** > 0
- **Height** (input_control) extent.y → integer
  Height of the region to be changed.
  Default value: 100
  Suggested values: **Height** ∈ \{64, 128, 256, 512\}
  Typical range of values: 1 ≤ **Height** ≤ 512 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: **Height** > 0
- **Distance** (input_control) integer → integer
  Hamming distance between the old and new regions.
  Default value: 1000
  Suggested values: **Distance** ∈ \{100, 500, 1000, 5000, 10000\}
  Typical range of values: 0 ≤ **Distance** ≤ 10000 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: **Distance** ≥ 0 & & **Distance** < **Width** * **Height**

**Complexity**
Memory requirement of the generated region (worst case): \(O(2 \times **Width** \times **Height**).\)

**Result**

**hamming_change_region** returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via **set_system(**'no_object_result',<Result>**). If necessary, an exception is raised.

hamming_distance

Module:
Foundation

interjacent (Region : RegionInterjacent : Mode : )

Partition the image plane using given regions.

interjacent is obsolete and is only provided for reasons of backward compatibility.

interjacent partitions the image plane using the regions given in Region. The result is a region containing the extracted separating lines. The following modes of operation can be used:

'medial_axis' This mode is used for regions that do not touch or overlap. The operator will find separating lines between the regions which partition the background evenly between the input regions. This corresponds to the following calls:
complement('full', Region, Tmp)
skeleton(Tmp, Result)

'border' If the input regions do not touch or overlap this mode is equivalent to boundary(Region, Result), i.e., it replaces each region by its boundary. If regions are touching they are aggregated into one region. The corresponding output region then contains the boundary of the aggregated region, as well as the one pixel wide separating line between the original regions. This corresponds to the following calls:
boundary(Region, Tmp1, 'inner')
union1(Tmp1, Tmp2)
skeleton(Tmp2, Result)

'mixed' In this mode the operator behaves like the mode 'medial_axis' for non-overlapping regions. If regions touch or overlap, again separating lines between the input regions are generated on output, but this time including the “touching line” between regions, i.e., touching regions are separated by a line in the output region. This corresponds to the following calls:
erosion1(Region, Mask, Tmp1, 1)
union1(Tmp1, Tmp2)
complement(full, Tmp2, Tmp3)
skeleton(Tmp3, Result)

where Mask denotes the following “cross mask”:

×
× × ×
×
17.12. SEGMENTATION

Parameters

- **Region** (input_object) region(-array) ~ object
  Regions for which the separating lines are to be determined.
- **RegionInterjacent** (output_object) region ~ object
  Output region containing the separating lines.
- **Mode** (input_control) string ~ string
  Mode of operation.
  Default value: 'mixed'
  List of values: Mode ∈ ['medial_axis', 'border', 'mixed']

Example

```plaintext
read_image(Image,'forest_air1')
mean_image(Image,Mean,31,31)
dyn_threshold(Image,Mean,Seg,20,'light')
interjacent(Seg,Graph,'medial_axis')
dev_display(Graph)
```

Result

**interjacent** always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region',<'true'/false>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, connection, regiongrowing, pouring

17.12 Segmentation

**bin_threshold** ( Image : Region : )

Segment an image using an automatically determined threshold.

**bin_threshold** is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **binary_threshold** instead.

**bin_threshold** segments a single-channel gray value image using an automatically determined threshold. First, the relative histogram of the gray values is determined. Then, relevant minima are extracted from the histogram, which are used as parameters for a thresholding operation. In order to reduce the number of minima, the histogram is smoothed with a Gaussian, as in **auto_threshold**. The mask size is enlarged until there is only one minimum in the smoothed histogram. The selected region contains the pixels with gray values from 0 to the minimum or for real images from the smallest value to the respective minimum. This operator is, for example useful for the segmentation of dark characters on a light paper.
### Parameters

- **Image** (input_object) .........................................................singlechannelimage(-array) ～ object : byte / uint2 / real  
  Input image.

- **Region** (output_object) ...................................................... region(-array) ～ object  
  Dark regions of the image.

#### Example

```plaintext
read_image (Image, 'letters')
bin_threshold (Image, Seg)
connection (Seg, Connected)
```

#### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

### Module

**class_ndim_box** (MultiChannelImage : Regions : ClassifHandle : )

Classify pixels using hyper-cuboids.

**class_ndim_box** is obsolete and is only provided for reasons of backward compatibility.

**class_ndim_box** classifies the pixels of the multi-channel image given in **MultiChannelImage**. To do so, the classificator **ClassifHandle** created with **create_class_box** is used. The classificator can be trained using **learn_ndim_box** or as described with **create_class_box**. More information on the structure of the classificator can be found also under that operator.

**MultiChannelImage** is a multi channel image. Its pixel values are used for the classification.

#### Parameters

- **MultiChannelImage** (input_object) ...... (multichannel-)image(-array) ～ object : byte / direction / cyclic / int1 / int2 / int4 / real  
  Multi channel input image.

- **Regions** (output_object) .............................. region-array ～ object  
  Classification result.

- **ClassifHandle** (input_control) .................. class_box ～ handle  
  Handle of the classifier.

#### Example

```plaintext
read_image(Image, 'montery')
development(Image)
development_set_color('green')
disp_message (WindowHandle, 'Draw learning region',
  'window', 12, 12, 'black', 'true')
draw_region(Reg1,WindowHandle)
reduce_domain(Image,Reg1,Foreground)
development_set_color('red')
disp_message (WindowHandle, 'Draw background region',
  'window', 12, 12, 'black', 'true')
draw_region(Reg2,WindowHandle)
```
reduce_domain(Image,Reg2,Background)
disp_message (WindowHandle, 'Training... ',
    'window', 12, 12, 'black', 'true')
create_class_box(ClassifHandle)
learn_ndim_box(Foreground,Background,Image,ClassifHandle)
disp_message (WindowHandle, 'Classification ',
    'window', 12, 12, 'black', 'true')
class_ndim_box(Image,Res,ClassifHandle)
dev_set_draw('fill')
dev_display (Res)
close_class_box(ClassifHandle)

 Complexity

Let $N$ be the number of hyper-cuboids and $A$ be the area of the input region. Then the runtime complexity is $O(N,A)$.

 Result

class_ndim_box returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags 'no_object_result', 'empty_region_result', and 'store_empty_region' with set_system. If necessary, an exception is raised.

 Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

 Module

Foundation

expand_line ( Image : RegionExpand : Coordinate, ExpandType, RowColumn, Threshold : )

Expand a region starting at a given line.

expand_line is obsolete and is only provided for reasons of backward compatibility.

expand_line generates a region by expansion, starting at a given line (row or column). The expansion is terminated when the current gray value differs by more than Threshold from the mean gray value along the line (ExpandType = 'mean') or from the previously added gray value (ExpandType = 'gradient').

 Parameters

* Image (input_object) ................................................. singlechannelimage(-array) $\rightarrow$ object : byte
  Input image.

* RegionExpand (output_object) .................................................. region(-array) $\rightarrow$ object
  Extracted segments.

* Coordinate (input_control) ...................................................... integer $\rightarrow$ integer
  Row or column coordinate.

 Default value: 256

 Suggested values: Coordinate $\in \{16, 64, 128, 200, 256, 300, 400, 511\}$

 Restriction: Coordinate $\geqslant 0$
ExpandType (input_control) .......................... string \rightarrow string
Stopping criterion.
Default value: 'gradient'
List of values: ExpandType \in \{ 'gradient', 'mean' \}

RowColumn (input_control) .......................... string \rightarrow string
Segmentation mode (row or column).
Default value: 'row'
List of values: RowColumn \in \{ 'row', 'column' \}

Threshold (input_control) .......................... number \rightarrow real / integer
Threshold for the expansion.
Default value: 3.0
Suggested values: Threshold \in \{ 0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 13.0, 17.0, 20.0, 30.0 \}
Typical range of values: 1.0 \leq Threshold \leq 255.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0
Restriction: Threshold \geq 0.0 && Threshold \leq 255.0

Example

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[]) {
  HImage  image (argv[1]),
            gauss;
  HWindow win;

  win.SetDraw ("margin");
  win.SetColored (12);
  image.Display  (win);

  gauss = image.GaussImage (5);

  HRegionArray reg = gauss.ExpandLine (100, "mean", "row", 5.0);

  reg.Display (win);
  win.Click  ()
  return  (0);
}
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

binomial_filter, gauss_filter, smooth_image, anisotropic_diffusion, median_image, affine_trans_image, rotate_image

Possible Successors

intersection, opening, closing
Train a classifier using a multi-channel image.

learn_ndim_box is obsolete and is only provided for reasons of backward compatibility.

learn_ndim_box trains the classifier ClassifHandle with the gray values of MultiChannelImage using the points in Foreground as training sample. The points in Background are to be rejected by the classifier. The classifier trained thus can be used in class_ndim_box to segment multi-channel images. Foreground are the points that should be found, Background contains the points that should not be found.

Each pixel is trained once during the training process. For points in Foreground the class “0” is used, while for Background “1” is used. Pixels are trained by alternating points from Foreground with points from Background. If one region is smaller than the other, pixels are taken cyclically from the smaller region until the larger region is exhausted. learn_ndim_box later accepts only points that can be classified into class “0”.

From a user’s point of view the key difference between learn_ndim_norm and learn_ndim_box is that in the latter case the rejection class affects the classification process itself. Here, a hyper plane is generated that separates Foreground and Background classes, so that no points in feature space are classified incorrectly. As for learn_ndim_norm, however, an overlap between Foreground and Background class is allowed. This has its effect on the return value Quality. The larger the overlap, the smaller this value.

All channels must be of the same type.

Parameters

- **Foreground** (input_object) region(-array) \( \sim \) object Foreground pixels to be trained.
- **Background** (input_object) region(-array) \( \sim \) object Background pixels to be trained (rejection class).
- **MultiChannelImage** (input_object) (multichannel-)image(-array) \( \sim \) object : byte / direction / cyclic / int1 / int2 / int4 / real Multi-channel training image.
- **ClassifHandle** (input_control) class_box \( \sim \) handle Handle of the classifier.

Complexity

Let \( N \) be the number of generated hyper-cuboids and \( A \) be the area of the larger input region. Then the runtime complexity is \( O(N \times A) \).

Result

learn_ndim_box returns 2 (H_MSG_TRUE) if all parameters are correct and there is an active classifier. The behavior with respect to the input images can be determined by setting the values of the flags 'no_object_result' and 'empty_region_result' with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_class_box, draw_region

Possible Successors

class_ndim_box, descript_class_box

Alternatives

17.13 Tools

approx_chain ( : : Row, Column, MinWidthCoord, MaxWidthCoord, ThreshStart, ThreshEnd, ThreshStep, MinWidthSmooth, MaxWidthSmooth, MinWidthCurve, MaxWidthCurve, Weight1, Weight2, Weight3 : ArcCenterRow, ArcCenterCol, ArcAngle, ArcBeginRow, ArcBeginCol, LineBeginRow, LineBeginCol, LineEndRow, LineEndCol, Order )

Approximate a contour by arcs and lines.

approx_chain is obsolete and is only provided for reasons of backward compatibility.

The coordinates of a curve are approximated by a row of lines and arcs. The procedure tries values from a user-definable range for certain parameters. The limits of these ranges are explicitly stated in the parameter list of the function (MinWidthCoord ... MaxWidthCoord, ThreshStart ... ThreshEnd, MinWidthSmooth ... MaxWidthSmooth, MinWidthCurve ... MaxWidthCurve). Additionally, the step width for the parameter area of the threshold value for pointed corners has to be indicated (ThreshStep). By narrowing the covered areas the runtime of the calculation can be shortened, but the result may deteriorate.

The parameters Weight1, Weight2 and Weight3 indicate whether the desired weighting is placed more on precision of the approximation, obtaining as much large segments as possible or as few small segments as possible. Thus, for (Weight1,Weight2,Weight3) (1,0,0) creates a very precise approximation and (0,1,1) an approximation with as few large segments as possible.

The result of the procedure is returned separately as arcs and lines. If one is interested in the sequence of the segments the individual resulting elements can be read successively from the resulting tuples; the sequence can be taken from the return parameter order (0: next element is next line segment, 1: next element is next arc segment).

Attention

Contours which can possibly consist of only one segment should also be examined with a threshold maximum (ThreshEnd) $> 1.0$, because otherwise at least one “corner point” is determined in any case.

Parameters

- **Row** (input_control) .......................................................... point.y-array $\sim$ integer
  Row of the contour.
  Default value: 32

- **Column** (input_control) ...................................................... point.x-array $\sim$ integer
  Column of the contour.
  Default value: 32

- **MinWidthCoord** (input_control) ......................................... real $\sim$ real
  Minimum width of Gauss operator for coordinate smoothing ($> 0.4$).
  Default value: 0.5
  Suggested values: MinWidthCoord $\in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}$
  Typical range of values: $0.4 \leq \text{MinWidthCoord} \leq 3.0$ (lin)
  Minimum increment: 0.01
  Recommended increment: 0.1
\(\text{MaxWidthCoord} \text{(input control)} \quad \text{real} \quad \text{real}\)

Maximum width of Gauss operator for coordinate smoothing (\(> 0.4\)).

Default value: 2.4

Suggested values: \(\text{MaxWidthCoord} \in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}\)

Typical range of values: \(0.4 \leq \text{MaxWidthCoord} \leq 3.0 \text{ (lin)}\)

Minimum increment: 0.01

Recommended increment: 0.1

\(\text{ThreshStart} \text{(input control)} \quad \text{real} \quad \text{real}\)

Minimum threshold value of the curvature for accepting a corner (relative to the largest curvature present).

Default value: 0.3

Suggested values: \(\text{ThreshStart} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8\}\)

Typical range of values: \(0.1 \leq \text{ThreshStart} \leq 0.9 \text{ (lin)}\)

Minimum increment: 0.01

Recommended increment: 0.1

\(\text{ThreshEnd} \text{(input control)} \quad \text{real} \quad \text{real}\)

Maximum threshold value of the curvature for accepting a corner (relative to the largest curvature present).

Default value: 0.9

Suggested values: \(\text{ThreshEnd} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8\}\)

Typical range of values: \(0.1 \leq \text{ThreshEnd} \leq 0.9 \text{ (lin)}\)

Minimum increment: 0.01

Recommended increment: 0.1

\(\text{ThreshStep} \text{(input control)} \quad \text{real} \quad \text{real}\)

Step width for threshold increase.

Default value: 0.2

Suggested values: \(\text{ThreshStep} \in \{0.3, 0.4, 0.5\}\)

Typical range of values: \(0.1 \leq \text{ThreshStep} \leq 0.9 \text{ (lin)}\)

Minimum increment: 0.01

Recommended increment: 0.1

\(\text{MinWidthSmooth} \text{(input control)} \quad \text{real} \quad \text{real}\)

Minimum width of Gauss operator for smoothing the curvature function (\(> 0.4\)).

Default value: 0.5

Suggested values: \(\text{MinWidthSmooth} \in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}\)

Typical range of values: \(0.4 \leq \text{MinWidthSmooth} \leq 3.0 \text{ (lin)}\)

Minimum increment: 0.01

Recommended increment: 0.1

\(\text{MaxWidthSmooth} \text{(input control)} \quad \text{real} \quad \text{real}\)

Maximum width of Gauss operator for smoothing the curvature function.

Default value: 2.4

Suggested values: \(\text{MaxWidthSmooth} \in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}\)

Typical range of values: \(0.4 \leq \text{MaxWidthSmooth} \leq 3.0 \text{ (lin)}\)

Minimum increment: 0.01

Recommended increment: 0.1

\(\text{MinWidthCurve} \text{(input control)} \quad \text{integer} \quad \text{integer}\)

Minimum width of curve area for curvature determination (\(> 0.4\)).

Default value: 2

Suggested values: \(\text{MinWidthCurve} \in \{2, 5, 7\}\)

Typical range of values: \(1 \leq \text{MinWidthCurve} \leq 12 \text{ (lin)}\)

Minimum increment: 1

Recommended increment: 2

\(\text{MaxWidthCurve} \text{(input control)} \quad \text{integer} \quad \text{integer}\)

Maximum width of curve area for curvature determination.

Default value: 12

Suggested values: \(\text{MaxWidthCurve} \in \{2, 5, 7\}\)

Typical range of values: \(1 \leq \text{MaxWidthCurve} \leq 20 \text{ (lin)}\)

Minimum increment: 1

Recommended increment: 2
Weight1 (input_control) real
Weighting factor for approximation precision.
Default value: 1.0
Suggested values: Weight1 ∈ {0.0, 0.5, 1.0}
Typical range of values: 0.0 ≤ Weight1 ≤ 1.0 (lin)
Minimum increment: 0.1
Recommended increment: 0.5

Weight2 (input_control) real
Weighting factor for large segments.
Default value: 1.0
Suggested values: Weight2 ∈ {0.0, 0.5, 1.0}
Typical range of values: 0.0 ≤ Weight2 ≤ 1.0 (lin)
Minimum increment: 0.1
Recommended increment: 0.5

Weight3 (input_control) real
Weighting factor for small segments.
Default value: 1.0
Suggested values: Weight3 ∈ {0.0, 0.5, 1.0}
Typical range of values: 0.0 ≤ Weight3 ≤ 1.0 (lin)
Minimum increment: 0.1
Recommended increment: 0.5

ArcCenterRow (output_control) arc.center.y-array integer
Row of the center of an arc.

ArcCenterCol (output_control) arc.center.x-array integer
Column of the center of an arc.

ArcAngle (output_control) arc.angle.rad-array real
Angle of an arc.

ArcBeginRow (output_control) arc.begin.y-array integer
Row of the starting point of an arc.

ArcBeginCol (output_control) arc.begin.x-array integer
Column of the starting point of an arc.

LineBeginRow (output_control) line.begin.y-array integer
Row of the starting point of a line segment.

LineBeginCol (output_control) line.begin.x-array integer
Column of the starting point of a line segment.

LineEndRow (output_control) line.end.y-array integer
Row of the ending point of a line segment.

LineEndCol (output_control) line.end.x-array integer
Column of the ending point of a line segment.

Order (output_control) integer-array integer
Sequence of line (value 0) and arc segments (value 1).

set_i(WindowHandleTuple,WindowHandle,0);
set_line_width(WindowHandle,4);
if (nob>0) T_disp_arc(Bzl,Bzc,Br,Bwl,Bwc);
set_line_width(WindowHandle,1);
if (nol>0) T_disp_line(WindowHandleTuple,Ll0,Lc0,Ll1,Lc1);

--- Result ---
The operator approx_chain returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

--- Execution Information ---

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

--- Possible Predecessors ---
sobel_amp,edges_image,get_region_contour,threshold,hysteresis_threshold

--- Possible Successors ---
set_line_width,disp_arc,disp_line

--- Alternatives ---
get_region_polygon,approx_chain_simple

--- See also ---
get_region_chain,smallest_circle,disp_circle,disp_line

--- Module ---

approx_chain_simple ( : : Row, Column : ArcCenterRow,
   ArcCenterCol, ArcAngle, ArcBeginRow, ArcBeginCol, LineBeginRow,
   LineBeginCol, LineEndRow, LineEndCol, Order )

Approximate a contour by arcs and lines.

approx_chain_simple is obsolete and is only provided for reasons of backward compatibility.

The contour of a curve is approximated by a sequence of lines and arcs.

The result of the procedure is returned separately as arcs and lines. If one is interested in the sequence of the segments the individual resulting elements can be read successively from the resulting tuples. The sequence can be taken from the return parameter order (0: next element is next line segment, 1: next element is next arc segment).
The operator `approx_chain_simple` behaves similarly as `approx_chain` except that in the case of `approx_chain_simple` the missing parameters are internally allocated as follows: MinWidthCoord = 1.0, MaxWidthCoord = 3.0, ThreshStart = 0.5, ThreshEnd = 0.9, ThreshStep = 0.3, MinWidthSmooth = 1.0, MaxWidthSmooth = 3.0, MinWidthCurve = 2, MaxWidthCurve = 9, Weight1 = 1.0, Weight2 = 1.0, Weight3 = 1.0.

---

### Parameters

- **Row** (input_control) ........................................ point.y-array ~ integer
  Row of the contour.
  **Default value:** 32

- **Column** (input_control) ........................................ point.x-array ~ integer
  Column of the contour.
  **Default value:** 32

- **ArcCenterRow** (output_control) ......................... arc.center.y-array ~ integer
  Row of the center of an arc.

- **ArcCenterCol** (output_control) ......................... arc.center.x-array ~ integer
  Column of the center of an arc.

- **ArcAngle** (output_control) .............................. arc.angle.rad-array ~ real
  Angle of an arc.

- **ArcBeginRow** (output_control) ......................... arc.begin.y-array ~ integer
  Row of the starting point of an arc.

- **ArcBeginCol** (output_control) ......................... arc.begin.x-array ~ integer
  Column of the starting point of an arc.

- **LineBeginRow** (output_control) ......................... line.begin.y-array ~ integer
  Row of the starting point of a line segment.

- **LineBeginCol** (output_control) ......................... line.begin.x-array ~ integer
  Column of the starting point of a line segment.

- **LineEndRow** (output_control) ......................... line.end.y-array ~ integer
  Row of the ending point of a line segment.

- **LineEndCol** (output_control) ......................... line.end.x-array ~ integer
  Column of the ending point of a line segment.

- **Order** (output_control) ................................ integer-array ~ integer
  Sequence of line (value 0) and arc segments (value 1).

---

### Example

```c
/* read edge image */
read_image(&Image,"fig1_kan");
/* construct edge region */
hysteresis_threshold(Image,&RK1,64,255,40,1);
connection(RK1,&Rand);
/* fetch chain code */
T_get_region_contour(Rand,&Rows,&Columns);
firstline = get_i(Tline,0);
firstcol = get_i(Tcol,0);
/* approximation with lines and circular arcs */
T_approx_chain_simple(Rows,Columns,
  &Bzl,&Bzc,&Br,&Bwl,&Bwc,&Ll0,&Lc0,&Ll1,&Lc1,&order);
nob = length_tuple(Bzl);
nol = length_tuple(Ll0);
/* draw lines and arcs */
set_i(WindowHandleTuple,WindowHandle,0);
set_line_width(WindowHandle,4);
if (nob>0) T_disp_arc(Bzl,Bzc,Br,Bwl,Bwc);
set_line_width(WindowHandle,1);
if (nol>0) T_disp_line(WindowHandleTuple,Ll0,Lc0,Ll1,Lc1);
```

---

### Result

The operator `approx_chain_simple` returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.
17.13. TOOLS

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
sobel_amp, edges_image, get_region_contour, threshold, hysteresis_threshold

Possible Successors
set_line_width, disp_arc, disp_line

Alternatives
get_region_polygon, approx_chain

Foundation

**clear_all_bar_code_models ( : : : )**

This operator is inoperable. It had the following function: Delete all bar code models and free the allocated memory.

`clear_all_bar_code_models` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `clear_all_bar_code_models`, the operator will be removed in future versions.

Attention
`clear_all_bar_code_models` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `clear_all_bar_code_models` *must not* be used in any application.

Result
The operator `clear_all_bar_code_models` returns the value 2 (H_MSG_TRUE) if all bar code models were freed correctly. Otherwise, an exception will be raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

**clear_all_barriers ( : : : )**

This operator is inoperable. It had the following function: Destroy all barrier synchronization objects.

`clear_all_barriers` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `clear_all_barriers`, the operator will be removed in future versions.

Attention
`clear_all_barriers` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `clear_all_barriers` *must not* be used in any application.
clear_all_barriers returns 2 (H_MSG_TRUE).

### Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Module

**Foundation**

clear_all_calib_data ( : : : )

Free the memory of all calibration data models.

**clear_all_calib_data** is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_calib_data**, the operator will be removed in future versions.

**Attention**

clear_all_calib_data exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_calib_data** must not be used in any application.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Module

**Calibration**

clear_all_camera_setup_models ( : : : )

Free the memory of all camera setup models.

**clear_all_camera_setup_models** is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_camera_setup_models**, the operator will be removed in future versions.

**Attention**

clear_all_camera_setup_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_camera_setup_models** must not be used in any application.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Module

**Calibration**
This operator is inoperable. It had the following function: Clear all Gaussian Mixture Models.
clear_all_class_gmm is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_class_gmm, the operator will be removed in future versions.

Attention
clear_all_class_gmm exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_class_gmm must not be used in any application.

Result
clear_all_class_gmm always returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

Foundation

---

This operator is inoperable. It had the following function: Clear all k-NN classifiers.
clear_all_class_knn is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_class_knn, the operator will be removed in future versions.

Attention
clear_all_class_knn exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_class_knn must not be used in any application.

Result
clear_all_class_knn always returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

clear_all_class_lut is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_class_lut, the operator will be removed in future versions.

Attention

clear_all_class_lut exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_class_lut must not be used in any application.

Result

clear_all_class_lut always returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

Foundation

clear_all_class_mlp ( : : : )

This operator is inoperable. It had the following function: Clear all multilayer perceptrons.

clear_all_class_mlp is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_class_mlp, the operator will be removed in future versions.

Attention

clear_all_class_mlp exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_class_mlp must not be used in any application.

Result

clear_all_class_mlp always returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

Foundation

clear_all_class_svm ( : : : )

This operator is inoperable. It had the following function: Clear all support vector machines.

clear_all_class_svm is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_class_svm, the operator will be removed in future versions.

Attention

clear_all_class_svm exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_class_svm must not be used in any application.
**clear_all_class_svm** always returns 2 (H_MSG_TRUE).

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

**clear_all_class_train_data** ( : : : )

This operator is inoperable. It had the following function: Clear all training data for classifiers.

**clear_all_class_train_data** is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_class_train_data**, the operator will be removed in future versions.

**Attention**

**clear_all_class_train_data** exists solely for the purpose of implementing the “reset program” functionality in HDevelop.

**Result**

**clear_all_class_train_data** returns the value 2 (H_MSG_TRUE).

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

**clear_all_color_trans_luts** ( : : : )

This operator is inoperable. It had the following function: Delete all look-up-tables of the color space transformation.

**clear_all_color_trans_luts** is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_color_trans_luts**, the operator will be removed in future versions.

**Attention**

After execution of **clear_all_color_trans_luts** all handles to look-up-tables become invalid. **clear_all_color_trans_luts** exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_color_trans_luts** must not be used in any application.

**Result**

The operator **clear_all_color_trans_luts** returns the value 2 (H_MSG_TRUE) if all look-up-tables were successfully released. Otherwise, an exception will be raised.

**Execution Information**
• Multithreading type: exclusive (runs in parallel only with independent operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

 clear_all_component_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all component models.
clear_all_component_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_component_models, the operator will be removed in future versions.

 Attention

 clear_all_component_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_component_models must not be used in any application.

 Result
clear_all_component_models always returns 2 (H_MSG_TRUE).

 Execution Information

 • Multithreading type: reentrant (runs in parallel with non-exclusive operators).
 • Multithreading scope: global (may be called from any thread).
 • Processed without parallelization.

 clear_all_conditions ( : : : )

This operator is inoperable. It had the following function: Destroy all condition synchronization objects.
clear_all_conditions is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_framegrabbers, the operator will be removed in future versions.

 Attention

 clear_all_conditions exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_conditions must not be used in any application.

 Result
clear_all_conditions returns 2 (H_MSG_TRUE).

 Execution Information

 • Multithreading type: independent (runs in parallel even with exclusive operators).
 • Multithreading scope: global (may be called from any thread).
 • Processed without parallelization.
**clear_all_data_code_2d_models** ( : : : )

This operator is inoperable. It had the following function: Delete all 2D data code models and free the allocated memory.

clear_all_data_code_2d_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_data_code_2d_models, the operator will be removed in future versions.

**clear_all_deformable_models** ( : : : )

This operator is inoperable. It had the following function: Free the memory of all deformable models.

clear_all_deformable_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_deformable_models, the operator will be removed in future versions.

**clear_all_descriptor_models** ( : : : )

This operator is inoperable. It had the following function: Free the memory of all descriptor models in RAM.

clear_all_descriptor_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_descriptor_models, the operator will be removed in future versions.
CHAPTER 17 LEGACY

Result

If the operator is successful, `clear_descriptor_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**clear_all_text_models** ( : : : )

This operator is inoperable. It had the following function: Clear all text models.

clear_all_text_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_text_models, the operator will be removed in future versions.
clear_all_text_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_text_models must not be used in any application.

**Result**
clear_all_text_models returns the value 2 (H_MSG_TRUE).

**Execution Information**
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**clear_all_text_results ( : : : )**

This operator is inoperable. It had the following function: Clear all text results.
clear_all_text_results is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_text_results, the operator will be removed in future versions.

**Attention**
clear_all_text_results exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_text_results must not be used in any application.

**Result**
clear_all_text_results returns the value 2 (H_MSG_TRUE).

**Execution Information**
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**clear_all_training_components ( : : : )**

This operator is inoperable. It had the following function: Free the memory of all component training results.
clear_all_training_components is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use clear_all_training_components, the operator will be removed in future versions.

**Attention**
clear_all_training_components exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_training_components must not be used in any application.

**Result**
clear_all_training_components always returns 2 (H_MSG_TRUE).

**Execution Information**
clear_all_variation_models ( : : : )

This operator is inoperable. It had the following function: Free the memory of all variation models.
clear_all_variation_models is obsolete, inoperable and is only provided for reasons of backward compatibility. New applications should not use clear_all_variation_models, the operator will be removed in future versions.

Attention

clear_all_variation_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. clear_all_variation_models must not be used in any application.

Result
clear_all_variation_models always returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

close_all_bg_esti ( : : : )

This operator is inoperable. It had the following function: Delete all background estimation data sets.
close_all_bg_esti is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_bg_esti, the operator will be removed in future versions.

Attention

close_all_bg_esti exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_bg_esti must not be used in any application.

Result
If it is possible to close the background estimation data sets the operator close_all_bg_esti returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
**close_all_class_box** ( : : : )

This operator is inoperable. It had the following function: Destroy all classifiers.

close_all_class_box is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_class_box, the operator will be removed in future version.

Attention

close_all_class_box exists solely for the purpose of implementing the “reset program” functionality in HDdevelop. close_all_class_box must not be used in any application.

**Result**

If it is possible to close the classifiers the operator close_all_class_box returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Execution Information**

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

Foundation

---

**close_all_files** ( : : : )

This operator is inoperable. It had the following function: Close all open files.

close_all_files is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_files, the operator will be removed in future version.

Attention

close_all_files exists solely for the purpose of implementing the “reset program” functionality in HDdevelop. close_all_files must not be used in any application.

**Result**

If it is possible to close the files the operator close_all_files returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

---

**close_all_framegrabbers** ( : : : )

This operator is inoperable. It had the following function: Close all image acquisition devices.

close_all_framegrabbers is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_framegrabbers, the operator will be removed in future versions.
**Attention**
close_all_framegrabbers exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_framegrabbers must not be used in any application.

For a multithreaded application all image acquisition operators (as listed in open_framegrabber) are an own group in which info_framegrabber, open_framegrabber, close_framegrabber and close_all_framegrabbers are executed exclusively.

Thus, info_framegrabber, open_framegrabber, close_framegrabber and close_all_framegrabbers block the concurrent execution of all other operators within this group, but run in parallel with all non-exclusive operators outside of this group.

**Result**
If it is possible to close all image acquisition devices, the operator close_all_framegrabbers returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

**Execution Information**
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

close_all_measures ( : : : )
```

This operator is inoperable. It had the following function: Delete all measure objects.

close_all_measures is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_measures, the operator will be removed in future versions.

**Attention**
close_all_measures exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_measures must not be used in any application.

**Result**
close_all_measures always returns 2 (H_MSG_TRUE).

**Execution Information**
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

1D Metrology

```plaintext
close_all_ocrs ( : : : )
```

This operator is inoperable. It had the following function: Destroy all OCR classifiers.

close_all_ocrs is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_ocrs, the operator will be removed in future versions.

**Attention**
close_all_ocrs exists solely for the purpose of implementing the “reset program” functionality in HDevelop. close_all_ocrs must not be used in any application.

**Result**
close_all_ocrs always returns 2 (H_MSG_TRUE).

**Execution Information**
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
close_all_ocrs exists solely for the purpose of implementing the “reset program” functionality in HDevelop.
close_all_ocrs must not be used in any application.

Result
If it is possible to close the OCR classifiers the operator close_all_ocrs returns the value 2 (H_MSG_TRUE).
Otherwise an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
OCR/OCV

close_all_ocvs ( : : : )

This operator is inoperable. It had the following function: Clear all OCV tools.
close_all_ocvs is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_ocvs, the operator will be removed in future versions.

Attention
close_all_ocvs exists solely for the purpose of implementing the “reset program” functionality in HDevelop.
close_all_ocvs must not be used in any application.

Result
close_all_ocvs returns always 2 (H_MSG_TRUE).

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
OCR/OCV

close_all_serials ( : : : )

This operator is inoperable. It had the following function: Close all serial devices.
close_all_serials is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use close_all_serials, the operator will be removed in future versions.

Attention
close_all_serials exists solely for the purpose of implementing the “reset program” functionality in HDevelop.
close_all_serials must not be used in any application.

Result
close_all_serials returns always 2 (H_MSG_TRUE).

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

• Processed without parallelization.

**close_all_sockets** ( : : : )

This operator is inoperable. It had the following function: Close all opened sockets.

`close_all_sockets` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `close_all_sockets`, the operator will be removed in future versions.

**Execution Information**

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

• Multithreading scope: global (may be called from any thread).

• Processed without parallelization.

**filter_kalman** ( : : Dimension, Model, Measurement, PredictionIn : PredictionOut, Estimate )

Estimate the current state of a system with the help of the Kalman filtering.

**filter_kalman** is obsolete and is only provided for reasons of backward compatibility.

The operator `filter_kalman` returns an estimate of the current state (or also a prediction of a future state) of a discrete, stochastically disturbed, linear system. In practice, Kalman filters are used successfully in image processing in the analysis of image sequences (background identification, lane tracking with the help of line tracing or region analysis, etc.). A short introduction concerning the theory of the Kalman filters will be followed by a detailed description of the routine `filter_kalman` itself.

**KALMAN FILTER:** A discrete, stochastically disturbed, linear system is characterized by the following markers:

• State \( x(t) \): Describes the current state of the system (speeds, temperatures,...).

• Parameter \( u(t) \): Inputs from outside into the system.

• Measurement \( y(t) \): Measurements gained by observing the system. They indicate the state of the system (or at least parts of it).

• An output function describing the dependence of the measurements on the state.

• A transition function indicating how the state changes with regard to time, the current value and the parameters.

The output function and the transition function are linear. Their application can therefore be written as a multiplication with a matrix.

The transition function is described with the help of the transition matrix \( A(t) \) and the parameter matrix \( G(t) \), the initial function is described by the measurement matrix \( C(t) \). Hereby \( C(t) \) characterizes the dependency of the new state on the old, \( G(t) \) indicates the dependency on the parameters. In practice it is rarely possible (or at least too time consuming) to describe a real system and its behavior in a complete and exact way. Normally only a relatively small number of variables will be used to simulate the behavior of the system. This leads to an error, the so called system error (also called system disturbance) \( v(t) \).

The output function, too, is usually not exact. Each measurement is faulty. The measurement errors will be called \( w(t) \). Therefore the following system equations arise:
\[ x(t + 1) = A(t)x(t) + G(t)u(t) + v(t) \]
\[ y(t) = c(t)x(t) + w(t) \]

The system error \( v(t) \) and the measurement error \( w(t) \) are not known. As far as systems are concerned which are interpreted with the help of the Kalman filter, these two errors are considered as Gaussian distributed random vectors (therefore the expression “stochastically disturbed systems”). Therefore the system can be calculated, if the corresponding expected values for \( v(t) \) and \( w(t) \) as well as the covariance matrices are known.

The estimation of the state of the system is carried out in the same way as in the Gaussian-Markov-estimation. However, the Kalman filter is a recursive algorithm which is based only on the current measurements \( y(t) \) and the latest state \( x(t) \). The latter implicitly also includes the knowledge about earlier measurements.

A suitable estimate value \( x_0 \), which is interpreted as the expected value of a random variable for \( x(0) \), must be indicated for the initial value \( x(0) \). This variable should have an expected error value of 0 and the covariance matrix \( P_0 \) which also has to be indicated. At a certain time \( t \) the expected values of both disturbances \( v(t) \) and \( w(t) \) should be 0 and their covariances should be \( Q(t) \) and \( R(t) \). \( x(t) \), \( v(t) \) and \( w(t) \) will usually be assumed to be not correlated (any kind of noise-process can be modelled - however the development of the necessary matrices by the user will be considerably more demanding). The following conditions must be met by the searched estimate values \( x^t \):

- The estimate values \( x^t \) are linearly dependent on the actual value \( x(t) \) and on the measurement sequence \( y(0), y(1), \ldots, y(t) \).
- \( x^t \) being hereby considered to meet its expectations, i.e. \( E x^t = E x(t) \).
- The grade criterion for \( x^t \) is the criterion of minimal variance, i.e. the variance of the estimation error defined as \( x(t) - x^t \), being as small as possible.

After the initialization
\[ \tilde{x}(0) = x_0, \quad \hat{P}(0) = P_0 \]
at each point in time \( t \) the Kalman filter executes the following calculation steps:

\[
\begin{align*}
(K - III) & \quad K(t) = \frac{P(t)C'(t)}{C(t)P(t)C'(t) + R(t)} \\
(K - IV) & \quad x^t = \tilde{x}(t) + K(t)(y(t) - C(t)\tilde{x}(t)) \\
(K - V) & \quad \hat{P}(t) = \hat{P}(t) - K(t)C(t)\hat{P}(t) \\
(K - I) & \quad \tilde{x}(t + 1) = A(t)x^t + G(t)u(t) \\
(K - II) & \quad \hat{P}(t + 1) = A(t)\hat{P}(t)A'(t) + Q(t)
\end{align*}
\]

Hereby \( \hat{P}(t) \) is the covariance matrix of the estimation error, \( \tilde{x}(t) \) is the extrapolation value respective the prediction value of the state, \( \hat{P}(t) \) are the covariances of the prediction error \( \tilde{x} - x \), \( K \) is the amplifier matrix (the so called Kalman gain), and \( X^t \) is the transposed of a matrix \( X \).

Please note that the prediction of the future state is also possible with the equation (K-I). Sometimes this is very useful in image processing in order to determine “regions of interest” in the next image.

As mentioned above, it is much more demanding to model any kind of noise processes. If for example the system noise and the measurement noise are correlated with the corresponding covariance matrix \( L \), the equations for the Kalman gain and the error covariance matrix have to be modified:

\[
\begin{align*}
(K - III) & \quad K(t) = \frac{P(t)C'(t)+L(t)}{C(t)P(t)+C(t)L(t)+L'C(t)+R(t)} \\
(K - V) & \quad \hat{P}(t) = \left(\hat{P}(t) - K(t)C(t)\hat{P}(t)\right)\hat{P}(t) - K(t)L(t)
\end{align*}
\]

This means that the user himself has to establish the linear system equations from (K-I) up to (K-V) with respect to the actual problem. The user must therefore develop a mathematical model upon which the solution to the problem can be based. Statistical characteristics describing the inaccuracies of the system as well as the measurement errors, which are to be expected, thereby have to be estimated if they cannot be calculated exactly. Therefore the following individual steps are necessary:

1. Developing a mathematical model
2. Selecting characteristic state variables
3. Establishing the equations describing the changes of these state variables and their linearization (matrices $A$ and $G$)
4. Establishing the equations describing the dependency of the measurement values of the system on the state variables and their linearization (matrix $C$)
5. Developing or estimating of statistical dependencies between the system disturbances (matrix $Q$)
6. Developing or estimating of statistical dependencies between the measurement errors (matrix $R$)
7. Initialization of the initial state

As mentioned above, the initialization of the system (point 7) hereby necessitates to indicate an estimate $x_0$ of the state of the system at the time 0 and the corresponding covariance matrix $P_0$. If the exact initial state is not known, it is recommendable to set the components of the vector $x_0$ to the average values of the corresponding range, and to set high values for $P_0$ (about the size of the squares of the range). After a few iterations (when the number of the accumulated measurement values in total has exceeded the number of the system values), the values which have been determined in this way are also usable.

If on the other hand the initial state is known exactly, all entries for $P_0$ have to be set to 0, because $P_0$ describes the covariances of the error between the estimated value $x_0$ and the actual value $x(0)$.

**THE FILTER ROUTINE:**

A Kalman filter is dependent on a range of data which can be organized in four groups:

- **Model parameter:** transition matrix $A$, control matrix $G$ including the parameter $u$ and the measurement matrix $C$
- **Model stochastic:** system-error covariance matrix $Q$, system-error - measurement-error covariance matrix $L$, and measurement-error covariance matrix $R$
- **Measurement vector:** $y$
- **History of the system:** extrapolation vector $\hat{x}$ and extrapolation-error covariance matrix $\hat{P}$

Thereby many systems can work without input “from outside”, i.e. without $G$ and $u$. Further, system errors and measurement errors are normally not correlated ($L$ is dropped).

Actually the data necessary for the routine will be set by the following parameters:

**Dimension:** This parameter includes the dimensions of the status vector, the measurement vector and the controller vector. **Dimension** thereby is a vector $[n,m,p]$, whereby ‘$n$’ indicates the number of the state variables, ‘$m$’ the number of the measurement values and ‘$p$’ the number of the controller members. For a system without determining control (i.e. without influence “from outside”) therefore $[n,m,0]$ has to be passed.

**Model:** This parameter includes the lined up matrices (vectors) $A,C,Q,G,u$ and (if necessary) $L$ having been stored in row-major order. **Model** therefore is a vector of the length $n \times n + n \times m + m \times n + n \times p + p \times [n + n \times m]$. The last summand is dropped, in case the system errors and measurement errors are not correlated, i.e. there is no value for ‘$L$’.

**Measurement:** This parameter includes the matrix ‘$R$’ which has been stored in row-major order, and the measurement vector ‘$y$’ lined up. **Measurement** therefore is a vector of the dimension $n \times m + m$.

**PredictionIn** / **PredictionOut:** These two parameters include the matrix $\hat{P}$ (the extrapolation-error covariance matrix) which has been stored in row-major order and the extrapolation vector $\hat{x}$ lined up. This means, they are vectors of the length $n \times n + n$. **PredictionIn** therefore is an input parameter, which must contain @ $\hat{P}(t)$ and $\hat{x}(t)$ at the current time $t$. With **PredictionOut** the routine returns the corresponding predictions $\hat{P}(t + 1)$ and $\hat{x}(t + 1)$.

**Estimate:** With this parameter the routine returns the matrix $\hat{P}$ (the estimation-error covariance matrix) which has been stored in row-major order and the estimated state $\hat{x}$ lined up. **Estimate** therefore is a vector of the length $n \times n + n$.

Please note that the covariance matrices ($Q, R, \hat{P}, \hat{P}$) must of course be symmetric.
Parameters

- **Dimension** (input_control) ................................................................. integer-array $\rightsquigarrow$ integer
  The dimensions of the state vector, the measurement and the controller vector.
  **Default value:** [3,1,0]
  **Typical range of values:** $0 \leq \text{Dimension} \leq 30$

- **Model** (input_control) ................................................................. real-array $\rightsquigarrow$ real
  The lined up matrices $A, C, Q$, possibly $G$ and $u$, and if necessary $L$ which have been stored in row-major order.
  **Default value:** [1.0,1.0,0.5,0.0,0.1,0.0,0.0,0.1,0.0,0.0,0.54,3.79,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
  **Typical range of values:** $0.0 \leq \text{Model} \leq 10000.0$

- **Measurement** (input_control) ....................................................... real-array $\rightsquigarrow$ real
  The matrix $R$ stored in row-major order and the measurement vector $y$ lined up.
  **Default value:** [1.2,1.0]
  **Typical range of values:** $0.0 \leq \text{Measurement} \leq 10000.0$

- **PredictionIn** (input_control) ......................................................... real-array $\rightsquigarrow$ real
  The matrix $\hat{P}$ (the extrapolation-error covariances) stored in row-major order and the extrapolation vector $\hat{x}$ lined up.
  **Default value:** [0.0,0.0,0.0,0.0,0.180.5,0.0,0.0,0.0,100.0,0.0,100.0,0.0]
  **Typical range of values:** $0.0 \leq \text{PredictionIn} \leq 10000.0$

- **PredictionOut** (output_control) .................................................. real-array $\rightsquigarrow$ real
  The matrix $P^*$ (the extrapolation-error covariances) stored in row-major order and the extrapolation vector $\hat{x}$ lined up.

- **Estimate** (output_control) ............................................................ real-array $\rightsquigarrow$ real
  The matrix $\tilde{P}$ (the estimation-error covariances) stored in row-major order and the estimated state $\tilde{x}$ lined up.

Example

* Typical procedure:
  * To initialize the variables, which describe the model, e.g., with
    \begin{verbatim}
    read_kalman('kalman.init', Dim, Mod, Meas, Pred)
    \end{verbatim}
  * Generation of the first measurements (typical of the first image of an
    * image series) with an appropriate problem-specific procedure (there is a
    * fictitious procedure extract_features in example):
      * extract_features(Image1, Meas, Meas1)
  * first Kalman-Filtering:
    \begin{verbatim}
    filter_kalman(Dim, Mod, Meas1, Pred1, Pred1, Est1)
    \end{verbatim}
  * To use the estimate value (if need be the prediction too)
    * with a problem-specific procedure (here use_est):
      * use_est(Est1)
  * To get the next measurements (e.g. from the next image):
    * extract_next_features(Image2, Meas1, Meas2)
  * if need be Update of the model parameter (a constant model)
    * second Kalman-Filtering:
      \begin{verbatim}
      filter_kalman(Dim, Mod, Meas2, Pred1, Pred2, Est2)
      \end{verbatim}
      * use_est(Est2)
      * extract_next_features(Image3, Meas2, Meas3)
      * etc.

Result

If the parameter values are correct, the operator \texttt{filter\_kalman} returns the value 2 (H\_MSG\_TRUE). Otherwise an exception is raised.

Execution Information

HALCON 20.11.0.0
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

References

Calculate the intersection point of two lines.

**intersection_ll** ( : : RowA1, ColumnA1, RowA2, ColumnA2, RowB1, ColumnB1, RowB2, ColumnB2 : Row, Column, IsParallel )

**intersection_ll** is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator intersection_lines of the chapter Tools / Geometry instead.

The operator intersection_ll calculates the intersection point of two lines. As input the two points on each line are expected (RowA1,ColumnA1,RowA2,ColumnA2) and (RowB1,ColumnB1,RowB2,ColumnB2). The parameters Row and Column return the result of the calculation. If the lines are parallel, the values of Row and Column are undefined and IsParallel is 1. Otherwise, IsParallel is 0.

**Attention**

If the lines are parallel the values of Row and Column are undefined.

**Parameters**

- **RowA1** (input_control) .................................................. point.y(-array) ~ real / integer
  Row coordinate of the first point of the first line.

- **ColumnA1** (input_control) .............................................. point.x(-array) ~ real / integer
  Column coordinate of the first point of the first line.

- **RowA2** (input_control) .................................................. point.y(-array) ~ real / integer
  Row coordinate of the second point of the first line.

- **ColumnA2** (input_control) .............................................. point.x(-array) ~ real / integer
  Column coordinate of the second point of the first line.

- **RowB1** (input_control) .................................................. point.y(-array) ~ real / integer
  Row coordinate of the first point of the second line.

- **ColumnB1** (input_control) .............................................. point.x(-array) ~ real / integer
  Column coordinate of the first point of the second line.

- **RowB2** (input_control) .................................................. point.y(-array) ~ real / integer
  Row coordinate of the second point of the second line.

- **ColumnB2** (input_control) .............................................. point.x(-array) ~ real / integer
  Column coordinate of the second point of the second line.
Row (output_control) ................................. point.y(-array) ↦ real
  Row coordinate of the intersection point.

Column (output_control) .............................. point.x(-array) ↦ real
  Column coordinate of the intersection point.

IsParallel (output_control) ............................. number(-array) ↦ integer
  Are the two lines parallel?

Example

dev_set_color ('black')
RowLine1 := 350
ColLine1 := 250
RowLine2 := 300
ColLine2 := 300
Rows := 300
Columns := 50
disp_line (WindowHandle, RowLine1, ColLine1, RowLine2, ColLine2)
n := 0
for Rows := 40 to 200 by 4
  dev_set_color ('red')
  disp_line (WindowHandle, Rows, Columns, Rows+n, Columns+n)
  intersection_ll (Rows, Columns, Rows+n, Columns+n, RowLine1, ColLine1, 
  RowLine2, ColLine2, Row, Column, IsParallel)
  dev_set_color ('blue')
  disp_line (WindowHandle, Row, Column-2, Row, Column+2)
  disp_line (WindowHandle, Row-2, Column, Row+2, Column)
  n := n+8
endfor

Result

intersection_ll returns 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

partition_lines ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn,
  Feature, Operation, Min, Max : RowBeginOut, ColBeginOut,
  RowEndOut, ColEndOut, FailRowBOut, FailColBOut, FailRowEOut,
  FailColEOut )

Partition lines according to various criteria.

partition_lines is obsolete and is only provided for reasons of backward compatibility.
The operator partition_lines divides lines into two sets according to various criteria. For each input line the indicated features (Feature) are calculated. If each (Operation = 'and') or at least one (Operation = 'or') of the calculated features is within the given limits (Min, Max) the line is transferred into the first set (parameters RowBeginOut to ColEndOut), otherwise into the second set (parameters FailRowBOut to FailColEOut). The default values ‘min’ and ‘max’ of the parameters Min and Max are used to leave bottom and top limit, respectively, open.

Condition:  \( Min_i \leq Feature_i (\text{Line}) \leq Max_i \)

Possible values for Feature:
'length'  (Euclidean) length of the line
'row'   Line index of the center
'column' Column index of the center
'phi'   Orientation of the line ($-\frac{\pi}{2} < \varphi \leq \frac{\pi}{2}$)

Attention
If only one feature is used the value of Operation is meaningless. Several features are processed according to the sequence in which they are passed.

Parameters

- **RowBeginIn** (input_control) ........................................ line.begin.y-array  $\sim$ integer Row coordinates of the starting points of the input lines.
- **ColBeginIn** (input_control) ........................................ line.begin.x-array  $\sim$ integer Column coordinates of the starting points of the input lines.
- **RowEndIn** (input_control) ........................................ line.end.y-array  $\sim$ integer Row coordinates of the ending points of the input lines.
- **ColEndIn** (input_control) ........................................ line.end.x-array  $\sim$ integer Column coordinates of the ending points of the input lines.
- **Feature** (input_control) ............................................... string(-array)  $\sim$ string Features to be used for selection.
  - List of values: Feature $\in \{\text{length}, \text{row}, \text{column}, \text{phi}\}$
- **Operation** (input_control) ......................................... string  $\sim$ string Desired combination of the features.
  - List of values: Operation $\in \{\text{and}, \text{or}\}$
- **Min** (input_control) ................................................... string(-array)  $\sim$ string / integer / real Lower limits of the features or 'min'.
  - Default value: 'min'
- **Max** (input_control) ................................................... string(-array)  $\sim$ string / integer / real Upper limits of the features or 'max'.
  - Default value: 'max'
- **RowBeginOut** (output_control) ..................................... line.begin.y-array  $\sim$ integer Row coordinates of the starting points of the lines fulfilling the conditions.
- **ColBeginOut** (output_control) ..................................... line.begin.x-array  $\sim$ integer Column coordinates of the starting points of the lines fulfilling the conditions.
- **RowEndOut** (output_control) ...................................... line.end.y-array  $\sim$ integer Row coordinates of the ending points of the lines fulfilling the conditions.
- **ColEndOut** (output_control) ...................................... line.end.x-array  $\sim$ integer Column coordinates of the ending points of the lines fulfilling the conditions.
- **FailRowBOut** (output_control) .................................... line.begin.y-array  $\sim$ integer Row coordinates of the starting points of the lines not fulfilling the conditions.
- **FailColBOut** (output_control) .................................... line.begin.x-array  $\sim$ integer Column coordinates of the starting points of the lines not fulfilling the conditions.
- **FailRowEOut** (output_control) .................................... line.end.y-array  $\sim$ integer Row coordinates of the ending points of the lines not fulfilling the conditions.
- **FailColEOut** (output_control) .................................... line.end.x-array  $\sim$ integer Column coordinates of the ending points of the lines not fulfilling the conditions.

Result

The operator partition_lines returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

Module
Foundation

**read_kalman** ( : : FileName : Dimension, Model, Measurement, Prediction )

Read the description file of a Kalman filter.

**read_kalman** is obsolete and is only provided for reasons of backward compatibility.

The operator **read_kalman** reads the description file **FileName** of a Kalman filter. Kalman filters return an estimate of the current state (or even the prediction of a future state) of a discrete, stochastically disturbed, linear system. They are successfully used in image processing, especially in the analysis of image sequences. A Kalman filtering is based on a mathematical model of the system to be examined which at any point in time has the following characteristics:

**Model parameter:** transition matrix $A$, control matrix $G$ including the controller output $u$ and the measurement matrix $C$

**Model stochastic:** system-error covariance matrix $Q$, system-error - measurement-error covariance matrix $L$ and measurement-error covariance matrix $R$

**Estimate of the initial state of the system:** state $x_0$ and corresponding covariance matrix $P_0$

Many systems do not need entries “from outside”, and therefore $G$ and $u$ can be dropped. Further, system errors and measurement errors are normally not correlated ($L$ is dropped). The characteristics mentioned above can be stored in an ASCII-file and then can be read with the help of the operator **read_kalman**. This ASCII-file must have the following structure:

**Dimension row**
+ content row
+ matrix $A$
+ matrix $C$
+ matrix $Q$
[+ matrix $G$ + vector $u$ ]
[+ matrix $L$ ]
+ matrix $R$
[+ matrix $P_0$ ]
[+ vector $x_0$ ]

The dimension row thereby is always of the following form:

$n = \langle \text{integer} \rangle \ m = \langle \text{integer} \rangle \ p = \langle \text{integer} \rangle$

whereby $n$ indicates the number of the state variables, $m$ the number of the measurement values and $p$ the number of the controller members (see also **Dimension**). The maximal dimension will hereby be limited by a system constant (= 30 for the time being).

The content row has the following form:

$A \ast C \ast Q \ast G \ast u \ast L \ast R \ast P \ast x*$

and describes the following content of the file. Instead of ‘*’, ‘+’ (= parameter is available) respectively ‘-’ (= parameter is missing) have to be set. Please note that only the parameters marked by [...] in the above list may be
left out in the description file. If the initial state estimate \( a_0 \) is missing (i.e. ‘x-’), the components of the vector will supposed to be 0.0. If the covariance matrix \( P_0 \) of the initial state estimate is missing (i.e. ‘P-’), the error will be supposed to be tremendous. In this case the matrix elements will be set to 10000.0. This value seems to be very high, however, it is only sufficient if the range of components of the state vector \( x \) is smaller to the tenth power. \((r \times s)\) matrices will be stored per row in the following form:

\[
<\text{comment, i.e. string}>
< a_{11} > < a_{12} > \cdots < a_{1s} > \\
\vdots \quad \vdots \quad \vdots \\
< a_{r1} > < a_{r2} > \cdots < a_{rs} >
\]

(the spaces and line feed characters can be chosen at will), vectors will be stored correspondingly in the following form:

\[
<\text{comment, i.e.string}>
< a_1 > \cdots < a_k >
\]

The following parameter values are returned by the operator \texttt{read_kalman}:

**Dimension:** This parameter includes the dimensions of the status vector, the measurement vector and the controller vector. Dimension thereby is a vector \([n,m,p]\), whereby ‘\( n \)’ indicates the number of the state variables, ‘\( m \)’ the number of the measurement values and ‘\( p \)’ the number of the controller members. For a system without determining control (i.e. without influence “from outside”) therefore Dimension = \([n,m,0]\).

**Model:** This parameter includes the lined up matrices (vectors) ‘\( A, C, Q, G, u \)’ and (if necessary) ‘\( L \)’ having been stored in row-major order. Model therefore is a vector of the length \( n \times n + n \times m + n \times n + p + p + n \times m \). The last summand is dropped, in case the system errors and measurement errors are not correlated, i.e. there is no value for ‘\( L \)’.

**Measurement:** This parameter includes the matrix ‘\( R \)’ which has been stored in row-major order. Measurement therefore is vector of the dimension \( m \times m \).

**Prediction:** This parameter includes the matrix ‘\( P_0 \)’ (the error covariance matrix of the initial state estimate) and the initial state estimate ‘\( x_0 \)’ lined up. This means, it is a vector of the length \( n \times n + n \).

---

**Parameters**

- **FileName** (input_control) ................................................................. filename.read \( \sim \) string
  Description file for a Kalman filter.
  Default value: ‘kalman.init’

- **Dimension** (output_control) ......................................................... integer-array \( \sim \) integer
  The dimensions of the state vector, the measurement vector and the controller vector.

- **Model** (output_control) ................................................................. real-array \( \sim \) real
  The lined up matrices \( A, C, Q \), possibly \( G \) and \( u \), and if necessary \( L \) stored in row-major order.

- **Measurement** (output_control) ....................................................... real-array \( \sim \) real
  The matrix \( R \) stored in row-major order.

- **Prediction** (output_control) .......................................................... real-array \( \sim \) real
  The matrix \( P_0 \) (error covariance matrix of the initial state estimate) stored in row-major order and the initial state estimate \( x_0 \) lined up.

---

select_lines ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn,
Feature, Operation, Min, Max : RowBeginOut, ColBeginOut,
RowEndOut, ColEndOut )

Select lines according to various criteria.

select_lines is obsolete and is only provided for reasons of backward compatibility.

The operator select_lines chooses lines according to various criteria. For every input line the indicated features (Feature) are calculated. If each (Operation = 'and') or at least one (Operation = 'or') of the calculated features is within the given limits (Min, Max) the line is transferred into the output. The default values 'min' and 'max' of the parameters Min and Max are used to leave bottom and top limits, respectively, open.

Condition: \[ Min_i \leq \text{Feature}_i(\text{Line}) \leq Max_i \]

Possible values for Feature:
'length' (Euclidean) length of the line
'row' Line index of the center
'column' Column index of the center
'phi' Orientation of the line ($0 < \phi \leq \pi$)

Attention
If only one feature is used the value of Operation is meaningless. Several features are processed according to the sequence in which they are passed.

Parameters

- **RowBeginIn** (input_control) ........................................ line.begin.y-array $\rightarrow$ integer
  Row coordinates of the starting points of the input lines.
- **ColBeginIn** (input_control) ........................................ line.begin.x-array $\rightarrow$ integer
  Column coordinates of the starting points of the input lines.
- **RowEndIn** (input_control) ........................................ line.end.y-array $\rightarrow$ integer
  Row coordinates of the ending points of the input lines.
- **ColEndIn** (input_control) ........................................ line.end.x-array $\rightarrow$ integer
  Column coordinates of the ending points of the input lines.
- **Feature** (input_control) ............................................. string(-array) $\rightarrow$ string
  Features to be used for selection.
  Default value: 'length'
  List of values: Feature $\in$ { 'length', 'row', 'column', 'phi' }
- **Operation** (input_control) ........................................ string $\rightarrow$ string
  Desired combination of the features.
  Default value: 'and'
  List of values: Operation $\in$ { 'and', 'or' }
- **Min** (input_control) ................................................ string(-array) $\rightarrow$ string / integer / real
  Lower limits of the features or 'min'.
  Default value: 'min'
- **Max** (input_control) ................................................ string(-array) $\rightarrow$ string / integer / real
  Upper limits of the features or 'max'.
  Default value: 'max'
- **RowBeginOut** (output_control) ................................... line.begin.y-array $\rightarrow$ integer
  Row coordinates of the starting points of the output lines.
- **ColBeginOut** (output_control) ................................... line.begin.x-array $\rightarrow$ integer
  Column coordinates of the starting points of the output lines.
- **RowEndOut** (output_control) ................................... line.end.y-array $\rightarrow$ integer
  Row coordinates of the ending points of the output lines.
- **ColEndOut** (output_control) ................................... line.end.x-array $\rightarrow$ integer
  Column coordinates of the ending points of the output lines.

Result

The operator select_lines returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

select_lines_longest ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn, Num : RowBeginOut, ColBeginOut, RowEndOut, ColEndOut )

Select the longest input lines.

select_lines_longest is obsolete and is only provided for reasons of backward compatibility.

The operator select_lines_longest selects the Num longest input lines from the input lines described by the tuples RowBeginIn, ColBeginIn, RowEndIn and ColEndIn.

Parameters

- **RowBeginIn** (input_control) .......................................................... line.begin.y-array \( \rightarrow \) integer
  Row coordinates of the starting points of the input lines.
- **ColBeginIn** (input_control) .......................................................... line.begin.x-array \( \rightarrow \) integer
  Column coordinates of the starting points of the input lines.
- **RowEndIn** (input_control) .......................................................... line.end.y-array \( \rightarrow \) integer
  Row coordinates of the ending points of the input lines.
- **ColEndIn** (input_control) .......................................................... line.end.x-array \( \rightarrow \) integer
  Column coordinates of the ending points of the input lines.
- **Num** (input_control) .............................................................. integer \( \rightarrow \) integer
  (Maximum) desired number of output lines.
  Default value: 10
- **RowBeginOut** (output_control) .................................................. line.begin.y-array \( \rightarrow \) integer
  Row coordinates of the starting points of the output lines.
- **ColBeginOut** (output_control) .................................................. line.begin.x-array \( \rightarrow \) integer
  Column coordinates of the starting points of the output lines.
- **RowEndOut** (output_control) .................................................. line.end.y-array \( \rightarrow \) integer
  Row coordinates of the ending points of the output lines.
- **ColEndOut** (output_control) .................................................. line.end.x-array \( \rightarrow \) integer
  Column coordinates of the ending points of the output lines.

Result

The operator select_lines_longest returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

select_lines, partition_lines, detect_edge_segments, select_shape
Read an update file of a Kalman filter.

**update_kalman** is obsolete and is only provided for reasons of backward compatibility.

The operator **update_kalman** reads the update file **FileName** of a Kalman filter. Kalman filters return an estimate of the current state (or even the prediction of a future state) of a discrete, stochastically disturbed, linear system.

A Kalman filtering is based on a mathematical model of the system to be examined which at any point in time has the following characteristics:

**Model parameter:** transition matrix $A$, control matrix $G$ including the controller output $u$ and the measurement matrix $C$

**Model stochastic:** system-error covariance matrix $Q$, system-error - measurement-error covariance matrix $L$ and measurement-error covariance matrix $R$

**Measurement vector:** $y$

**History of the system:** extrapolation vector $\hat{x}$ and extrapolation-error covariance matrix $\hat{P}$

Many systems do not need entries “from outside” and therefore $G$ and $u$ can be dropped. Further, system errors and measurement errors are normally not correlated ($L$ is dropped). Some of the characteristics mentioned above may change dynamically (from one iteration to the next). The operator **update_kalman** serves to modify parts of the system according to an update file (ASCII) with the following structure (see also **read_kalman**):

```
  Dimension row
  + content row
  + matrix $A$
  + matrix $C$
  + matrix $Q$
  + matrix $G$ + vector $u$
  + matrix $L$
  + matrix $R$
```

The dimension row thereby has the following form:

```
n = <integer> m = <integer> p = <integer>
```

whereby $n$ indicates the number of the state variables, $m$ the number of the measurement values and $p$ the number of the controller members (see also DimensionIn / DimensionOut). The maximal dimension will hereby be limited by a system constant (≈ 30 for the time being). As in this case changes should take effect at a valid model, the dimensions $n$ and $m$ are invariant (and will only be indicated for purposes of control).

The content row has the following form:

```
A * C * Q * G * u * L * R*
```

and describes the further content of the file. Instead of `*'`, `+` (= parameter is available) respectively `-` (= parameter is missing) has to be set. In contrast to description files for **read_kalman**, the system description needs not be complete in this case. Only those parts of the system which are changed must be indicated. The indication of estimated values is unnecessary, as these values must stem from the latest filtering according to the structure of the filter.

$(r \times s)$ matrices will be stored in row-major order in the following form:

```
< comment, i.e. string >
< a_{11} > < a_{12} > \cdots < a_{1s} >
\vdots \quad \ddots \quad \vdots
< a_{r1} > < a_{r2} > \cdots < a_{rs} >
```
(the spaces/line feed characters can be chosen at will),
vectors will be stored correspondingly in the following form:

\[
< \text{comment}, \text{i.e. string} > \\
< a_1 > \quad \cdots \quad < a_k >
\]

The following parameter values of the operator \texttt{read_kalman} will be changed:

**DimensionIn/DimensionOut:** These parameters include the dimensions of the state vector, measurement vector and controller vector and therefore are vectors \([n,m,p]\), whereby ‘\(n\)’ indicates the number of the state variables, ‘\(m\)’ the number of the measurement values and ‘\(p\)’ the number of the controller members. ‘\(n\)’ and ‘\(m\)’ are invariant for a given system, i.e. they must not differ from corresponding input values of the update file. For a system without without influence “from outside” ‘\(p = 0\)’.

**ModelIn/ModelOut:** These parameters include the lined up matrices (vectors) ‘A, C, Q, G, u’ and if necessary ‘L’ which have been stored in row-major order. **ModelIn/ModelOut** therefore are vectors of the length 
\[
n \times n + n \times m + n \times n + n \times p + p[+n \times m].
\]
The last summand is dropped if system errors and measurement errors are not correlated, i.e. no value has been set for ‘\(L\)’.

**MeasurementIn/MeasurementOut:** These parameters include the matrix ‘R’ stored in row-major order, and therefore are vectors of the dimension \(m \times m\).

### Example

* The following values are describing the system *
  * DimensionIn = [3,1,0]
  * ModelIn = [1.0,1.0,0.5,0.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
  * MeasurementIn = [1,2]
* An example of the Updatefile:
  * n=3 m=1 p=0

HALCON 20.11.0.0
* A+C-Q-G-u-L-R-
* transitions at time t=15:
* 2 1 1
* 0 2 2
* 0 0 2
* 
* the results of update_kalman:
* 
* DimensionOut = [3,1,0]
* ModelOut = [2.0,1.0,0.0,0.0,2.0,2.0,0.0,0.0,2.0,1.0,0.0,0.0,
* 54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
* MeasurementOut = [1.2]

If the update file is readable and correct, the operator update_kalman returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

--- Execution Information ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

--- Module ---

17.14 XLD

union_straight_contours_histo_xld ( Contours : UnionContours,
SelectedContours : RefLineStartRow, RefLineStartColumn,
RefLineEndRow, RefLineEndColumn, Width, MaxWidth,
FilterSize : HistoValues )

Compute the union of neighboring straight contours that have a similar distance from a given line.

union_straight_contours_histo_xld is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators of the chapter 1D Measuring instead.

union_straight_contours_histo_xld merges neighboring XLD contours Contours if certain criteria are fulfilled.

The maximum and minimum distances of the contours to a given reference line are calculated. From this distances a histogram is created. If the histogram should be smoothed, FilterSize must be greater than one. Afterwards, the resulting histogram is divided into ranges (from minima to minima). Contours which lie in the same range are concatenated to a new contour. If the width of the range is greater than MaxWidth, all contours in this range are ignored (removed). If a contour lies in two ranges or more it is ignored, too. If there are parallel contours, there is a risk of merging neighboring contours.

The parameters of the regression lines are calculated newly for merged contours.

The resulting contours cannot be displayed.

--- Attention ---

Before the contour parameters can be returned by union_straight_contours_histo_xld, the parameters of the regression line to the contour must be calculated by calling regress_contours_xld. Note further that already closed contours are not considered for a union anymore.
### Parameters

- **Contours** (input_object) 
  Input XLD contours.

- **UnionContours** (output_object) 
  Output XLD contours.

- **SelectedContours** (output_object) 
  Output XLD contours.

- **RefLineStartRow** (input_control) 
  y coordinate of the starting point of the reference line.
  Default value: 0

- **RefLineStartColumn** (input_control) 
  x coordinate of the starting point of the reference line.
  Default value: 0

- **RefLineEndRow** (input_control) 
  y coordinate of the endpoint of the reference line.
  Default value: 0

- **RefLineEndColumn** (input_control) 
  x coordinate of the endpoint of the reference line.
  Default value: 0

- **Width** (input_control) 
  Maximum distance.
  Default value: 1

- **MaxWidth** (input_control) 
  Maximum width between two minima.
  Default value: 1

- **FilterSize** (input_control) 
  Size of smoothing filter
  Default value: 1
  Typical range of values: $1 \leq \text{FilterSize} \leq 63$

- **HistoValues** (output_control) 
  Output values of histogram.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
Chapter 18

Matching

18.1 Component-Based

**clear_component_model** ( : : ComponentModelID : )

*Free the memory of a component model.*

The operator `clear_component_model` frees the memory of a component model that was created by `create_component_model` or `create_trained_component_model`. After calling `clear_component_model`, the model can no longer be used. The handle `ComponentModelID` becomes invalid.

**Parameters**

▷ `ComponentModelID` (input_control) ................. component_model ~> handle
  Handle of the component model.

**Result**

If the handle of the model is valid, the operator `clear_component_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ComponentModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

`create_component_model`, `create_trained_component_model`, `read_component_model`, `write_component_model`

**Module**

Matching

**clear_training_components** ( : : ComponentTrainingID : )

*Free the memory of a component training result.*
The operator `clear_training_components` frees the memory of a training result that was created by `train_model_components`. After calling `clear_training_components`, the training result can no longer be used. The handle `ComponentTrainingID` becomes invalid.

### Parameters

- **ComponentTrainingID** (input_control) : component_training ~ handle
  
  Handle of the training result.

### Result

If the handle of the training result is valid, the operator `clear_training_components` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ComponentTrainingID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `train_model_components`, `write_training_components`

### Module

`cluster_model_components`

```c
cluster_model_components ( 
    TrainingImages : ModelComponents : ComponentTrainingID,
    AmbiguityCriterion, MaxContourOverlap, ClusterThreshold : )
```

*Adopt new parameters that are used to create the model components into the training result.*

With `cluster_model_components` you can modify parameters after a first training has been performed using `train_model_components`. `cluster_model_components` sets the criterion `AmbiguityCriterion` that is used to solve the ambiguities, the maximum contour overlap `MaxContourOverlap`, and the cluster threshold of the training result `ComponentTrainingID` to the specified values. A detailed description of these parameters can be found in the documentation of `train_model_components`. By modifying these parameters, the way in which the initial components are merged into rigid model components changes. For example, the greater the cluster threshold is chosen, the fewer initial components are merged. You can select suitable parameter values interactively by repeatedly calling `inspect_clustered_components` with different parameter values and then setting the chosen values by using `get_training_components`.

The rigid model components are returned in `ModelComponents`. In order to receive reasonable results, it is essential that the same training images that were used to perform the training with `train_model_components` are passed in `TrainingImages`. The pose of the newly clustered components within the training images is determined using the shape-based matching. As in `train_model_components`, one can decide whether the shape models should be pregenerated by using `set_system('pregenerate_shape_models',...)`. Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. `set_system('border_shape_models',...)` can be used to determine whether the models must lie completely within the training images or whether they can extend partially beyond the image border.
18.1. COMPONENT-BASED

Parameters

- **TrainingImages** (input_object) ........................................................ object : byte / uint2
  Training images that were used for training the model components.
- **ModelComponents** (output_object) .............................................. region(-array) ⇒ object
  Contour regions of rigid model components.
- **ComponentTrainingID** (input_control) ......................................... component_training ⇒ handle
  Handle of the training result.
- **AmbiguityCriterion** (input_control) ............................................ string ⇒ string
  Criterion for solving the ambiguities.
  Default value: 'rigidity'
- **MaxContourOverlap** (input_control) ......................................... real ⇒ real
  Maximum contour overlap of the found initial components.
  Default value: 0.2
  Suggested values: MaxContourOverlap ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: 0 <= MaxContourOverlap && MaxContourOverlap <= 1
- **ClusterThreshold** (input_control) ............................................. real ⇒ real
  Threshold for clustering the initial components.
  Default value: 0.5
  Suggested values: ClusterThreshold ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: 0 <= ClusterThreshold && ClusterThreshold <= 1

Example

* Get the model image.
  read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
  gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
  gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
  gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
  concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images
  gen_empty_obj (TrainingImages)
  for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-' + i + '02' + '.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
  endfor
* Extract the model components and train the relations.
  train_model_components (ModelImage, InitialComponentRegions, \n    TrainingImages, ModelComponents, 22, 60, 30, 0.65, \n    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.5, \n    ComponentTrainingID)
* Find the best value for the parameter ClusterThreshold.
  inspect_clustered_components (ModelComponents, ComponentTrainingID, \n    'rigidity', 0.2, 0.4)
* Adopt the ClusterThreshold into the training result.
  cluster_model_components (TrainingImages, ModelComponents, \n    ComponentTrainingID, 'rigidity', 0.2, 0.4)
* Create the component model based on the training result.
  create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, \n    0.5, 'auto', 'auto', 'none', \n    'use_polarity', 'false', ComponentModelID, \n    RootRanking)
Result

If the parameter values are correct, the operator `cluster_model_components` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system` (‘no_object_result’,<Result>). If necessary, an exception is raised.

---

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

Possible Predecessors

- `train_model_components`
- `inspect_clustered_components`

Possible Successors

- `get_training_components`
- `create_trained_component_model`
- `modify_component_relations`
- `write_training_components`
- `get_component_relations`
- `clear_training_components`

Module

Matching

```plaintext
create_component_model { ModelImage,
    ComponentRegions : : VariationRow, VariationColumn,
    VariationAngle, AngleStart, AngleExtent, ContrastLowComp,
    ContrastHighComp, MinSizeComp, MinContrastComp, MinScoreComp,
    NumLevelsComp, AngleStepComp, OptimizationComp, MetricComp,
    PregenerationComp : ComponentModelID, RootRanking }
```

Prepare a component model for matching based on explicitly specified components and relations.

create_component_model prepares patterns, which are passed in the form of a model image `ModelImage` and several regions `ComponentRegions`, as a component model for matching. The output parameter `ComponentModelID` is a handle for this model, which is used in subsequent calls to `find_component_model`. In contrast to `create_trained_component_model`, no preceding training with `train_model_components` needs to be performed before calling `create_component_model`.

Each of the regions passed in `ComponentRegions` describes a separate model component. Later, the index of a component region in `ComponentRegions` is used to denote the model component. The reference point of a component is the center of gravity of its associated region, which is passed in `ComponentRegions`. It can be calculated by calling `area_center`.

The relative movements (relations) of the model components can be set by passing `VariationRow`, `VariationColumn`, and `VariationAngle`. Because directly passing the relations is complicated, instead of the relations the variations of the model components are passed. The variations describe the movements of the components independently from each other relative to their poses in the model image `ModelImage`. The parameters `VariationRow` and `VariationColumn` describe the movement of the components in row and column direction by \( \pm \frac{1}{2} \text{VariationRow} \) and \( \pm \frac{1}{2} \text{VariationColumn} \), respectively. The parameter `VariationAngle` describes the angle variation of the component by \( \pm \frac{1}{2} \text{VariationAngle} \). Based on these values, the relations are automatically computed. The three parameters must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as `ComponentRegions`, in which case each parameter element refers to the corresponding model component in `ComponentRegions`.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations of the component model in an image.

Internally, a separate shape model is built for each model component (see `create_shape_model`). Therefore, the parameters `ContrastLowComp`, `ContrastHighComp`, `MinSizeComp`, `MinContrastComp`, `MinScoreComp`, `NumLevelsComp`, `AngleStepComp`, `OptimizationComp`, `MetricComp`, and `PregenerationComp` correspond to the parameters of `create_shape_model`, with the following differences: First, in the parameter `Contrast` of `create_shape_model` the upper as well as the lower threshold for the hysteresis threshold method can be passed. Additionally, a third value, which suppresses small connected
contour regions, can be passed. In contrast, the operator create_component_model offers three separate parameters ContrastHighComp, ContrastLowComp, and MinScoreComp in order to set these three values. Consequently, also the automatic computation of the contrast threshold(s) is different. If both hysteresis threshold should be automatically determined, both ContrastLowComp and ContrastHighComp must be set to ‘auto’. In contrast, if only one threshold value should be determined, ContrastLowComp must be set to ‘auto’ while ContrastHighComp must be set to an arbitrary value different from ‘auto’. Secondly, the parameter Optimization of create_shape_model provides the possibility to reduce the number of model points as well as the possibility to completely pregenerate the shape model. In contrast, the operator create_trained_component_model uses a separate parameter PregenerationComp in order to decide whether the shape models should be completely pregenerated or not. A third difference concerning the create_component_model should be noted. When using the shape-based matching, this parameter needs not be passed when preparing the shape model using create_shape_model, but only during the search using find_shape_model. In contrast, when preparing the component model it is favorable to analyze rotational symmetries of the model components and similarities between the model components. However, this analysis only leads to meaningful results if the value for MinScoreComp that is used during the search (see find_component_model) is already approximately known.

In addition to the parameters ContrastLowComp, ContrastHighComp, and MinSizeComp also the parameters MinContrastComp, NumLevelsComp, AngleStepComp, and OptimizationComp can be automatically determined by passing ‘auto’ for the respective parameters.

All component-specific input parameters (parameter names terminate with the suffix Comp) must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as the number of regions in ComponentRegions, in which case each parameter element refers to the corresponding element in ComponentRegions.

In addition to the individual shape models, the component model also contains information about the way the single model components must be searched relative to each other using find_component_model in order to minimize the computation time of the search. For this, the components are represented in a tree structure. First, the component that stands at the root of this search tree (root component) is searched. Then, the remaining components are searched relative to the pose of their predecessor in the search tree.

The root component can be passed as an input parameter of find_component_model during the search. To what extent a model component is suited to act as the root component depends on several factors. In principle, a model component that can be found in the image with a high probability should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as the root component. Additionally, the computation time that is associated with the root component during the search can serve as a criterion. A ranking of the model components that is based on the latter criterion is returned in RootRanking. In this parameter the indices of the model components are sorted in descending order according to their associated search time, i.e., RootRanking[0] contains the index of the model component that, chosen as root component, allows the fastest search. Note that the ranking returned in RootRanking represents only a coarse estimation. Furthermore, the calculation of the root ranking assumes that the image size as well as the value of the system parameter ‘border_shape_models’ are identical when calling create_component_model and find_component_model.

---

**Parameters**

- **ModelImage** (input_object) .............................................. (multichannel-)image \( \sim \) object : byte / uint2
  Input image from which the shape models of the model components should be created.

- **ComponentRegions** (input_object) .............................................. region-array \( \sim \) object
  Input regions from which the shape models of the model components should be created.

- **VariationRow** (input_control) .............................................. Integer(-array) \( \sim \) integer
  Variation of the model components in row direction.
  **Suggested values:** VariationRow ∈ \{0, 1, 2, 3, 4, 5, 10, 20, 30, 40, 50, 100, 150\}
  **Restriction:** VariationRow \(\geq\) 0

- **VariationColumn** (input_control) .............................................. Integer(-array) \( \sim \) integer
  Variation of the model components in column direction.
  **Suggested values:** VariationColumn ∈ \{0, 1, 2, 3, 4, 5, 10, 20, 30, 40, 50, 100, 150\}
  **Restriction:** VariationColumn \(\geq\) 0

- **VariationAngle** (input_control) .............................................. angle.rad(-array) \( \sim \) real
  Angle variation of the model components.
  **Suggested values:** VariationAngle ∈ \{0.0, 0.017, 0.035, 0.05, 0.07, 0.09, 0.17, 0.35, 0.52, 0.67, 0.87\}
  **Restriction:** VariationAngle \(\geq\) 0
CHAPTER 18 MATCHING

▷ **AngleStart** (input_control) .......................... angle.rad  $\sim$ real
Smallest rotation of the component model.
Default value: -0.39
Suggested values: $\text{AngleStart} \in [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]$

▷ **AngleExtent** (input_control) .......................... angle.rad  $\sim$ real
Extent of the rotation of the component model.
Default value: 0.79
Suggested values: $\text{AngleExtent} \in [6.28, 3.14, 1.57, 0.79, 0.39]$
Restriction: AngleExtent $\geq 0$

▷ **ContrastLowComp** (input_control) .......................... integer(-array)  $\sim$ integer / string
Lower hysteresis threshold for the contrast of the components in the model image.
Default value: ‘auto’
Suggested values: $\text{ContrastLowComp} \in \{\text{‘auto’, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}\}$
Restriction: ContrastLowComp $> 0$

▷ **ContrastHighComp** (input_control) .......................... integer(-array)  $\sim$ integer / string
Upper hysteresis threshold for the contrast of the components in the model image.
Default value: ‘auto’
Suggested values: $\text{ContrastHighComp} \in \{\text{‘auto’, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}\}$
Restriction: ContrastHighComp $> 0$ && ContrastHighComp $\geq$ ContrastLowComp

▷ **MinSizeComp** (input_control) .......................... integer(-array)  $\sim$ integer / string
Minimum size of the contour regions in the model.
Default value: ‘auto’
Suggested values: $\text{MinSizeComp} \in \{\text{‘auto’, 0, 5, 10, 20, 30, 40}\}$
Restriction: MinSizeComp $\geq 0$

▷ **MinContrastComp** (input_control) .......................... integer(-array)  $\sim$ integer / string
Minimum contrast of the components in the search images.
Default value: ‘auto’
Suggested values: $\text{MinContrastComp} \in \{\text{‘auto’, 10, 20, 20, 40}\}$
Restriction: MinContrastComp $\leq$ ContrastLowComp && MinContrastComp $\geq 0$

▷ **MinScoreComp** (input_control) .......................... real(-array)  $\sim$ real
Minimum score of the instances of the components to be found.
Default value: 0.5
Suggested values: $\text{MinScoreComp} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: $0 \leq \text{MinScoreComp} \leq 1$

▷ **NumLevelsComp** (input_control) .......................... integer(-array)  $\sim$ integer / string
Maximum number of pyramid levels for the components.
Default value: ‘auto’
List of values: $\text{NumLevelsComp} \in \{\text{‘auto’, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}\}$

▷ **AngleStepComp** (input_control) .......................... angle.rad(-array)  $\sim$ real / string
Step length of the angles (resolution) for the components.
Default value: ‘auto’
Suggested values: $\text{AngleStepComp} \in \{\text{‘auto’, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}\}$
Restriction: AngleStepComp $\geq 0$

▷ **OptimizationComp** (input_control) .......................... string  $\sim$ string
Kind of optimization for the components.
Default value: ‘auto’
List of values: $\text{OptimizationComp} \in \{\text{‘auto’, ‘none’, ‘point_reduction_low’, ‘point_reduction_medium’, ‘point_reduction_high’}\}$

▷ **MetricComp** (input_control) .......................... string(-array)  $\sim$ string
Match metric used for the components.
Default value: ‘use_polarity’
List of values: $\text{MetricComp} \in \{\text{‘use_polarity’, ‘ignore_global_polarity’, ‘ignore_local_polarity’, ‘ignore_color_polarity’}\}$
18.1. COMPONENT-BASED

- **PregenerationComp** (input_control) ................................................. string(-array) ↼ string
  Complete pregeneration of the shape models for the components if equal to 'true'.
  **Default value:** 'false'
  **List of values:** PregenerationComp ∈ {'true', 'false'}

- **ComponentModelID** (output_control) ........................................... component_model ↼ handle
  Handle of the component model.

- **RootRanking** (output_control) ............................................... integer(-array) ↼ integer
  Ranking of the model components expressing the suitability to act as the root component.

* Example *

* Read the model image.
  read_image (ModelImage, 'model_image.tif')
* Describe the model components.
  gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)
  gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)
  gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)
  concat_obj (ComponentRegions, Rectangle2, ComponentRegions)
  concat_obj (ComponentRegions, Rectangle3, ComponentRegions)
* Create the component model by explicitly specifying the relations.
  create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \
   rad(360), 15, 40, 15, 10, 0.8, 'auto', 'auto', \
   'none', 'use_polarity', 'false', ComponentModelID, \n   RootRanking)
* Find the component model in a run-time image.
  read_image (SearchImage, 'search_image.tif')
  find_component_model (SearchImage, ComponentModelID, RootRanking, 0, \
   rad(360), 0.5, 0, 0.5, 'stop_search', \
   'search_from_best', 'none', 0.8, 'least_squares', 0, \
   0.8, ModelStart, ModelEnd, Score, RowComp, \
   ColumnComp, AngleComp, ScoreComp, ModelComp)

* Result *

If the parameters are valid, the operator create_component_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

* Execution Information *

  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

HALCON 20.11.0.0
**create_trained_component_model**

```plaintext
create_trained_component_model { : : ComponentTrainingID,
    AngleStart, AngleExtent, MinContrastComp, MinScoreComp,
    NumLevelsComp, AngleStepComp, OptimizationComp, MetricComp,
    PregenerationComp : ComponentModelID, RootRanking }
```

**Prepare a component model for matching based on trained components.**

`create_trained_component_model` prepares the training result, which is passed in `ComponentTrainingID`, as a component model for matching. The output parameter `ComponentModelID` is a handle for this model, which is used in subsequent calls to `find_component_model`. In contrast to `create_component_model`, the model components must have been previously trained using `train_model_components` before calling `create_trained_component_model`.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations of the component model in an image.

Internally, a separate shape model is built for each model component (see `create_shape_model`). Therefore, the parameters `MinContrastComp`, `MinScoreComp`, `NumLevelsComp`, `AngleStepComp`, `OptimizationComp`, `MetricComp`, and `PregenerationComp` correspond to the parameters of `create_shape_model`, with the following differences: First, the parameter `OptimizationComp` provides the possibility to reduce the number of model points as well as the possibility to completely regenerate the shape model. In contrast, the operator `create_trained_component_model` uses a separate parameter `PregenerationComp` in order to decide whether the shape models should be completely pregenerated or not. A second difference concerning the parameter `MinScoreComp` should be noted. When using the shape-based matching, this parameter needs not be passed when preparing the shape model using `create_shape_model` but only during the search using `find_shape_model`. In contrast, when preparing the component model it is favorable to analyze rotational symmetries of the model components and similarities between the model components. However, this analysis only leads to meaningful results if the value for `MinScoreComp` that is used during the search (see `find_component_model`) is already approximately known. After the search with `find_component_model` the pose parameters of the components in a search image are returned. Note that the pose parameters refer to the reference points of the components. The reference point of a component is the center of gravity of its associated region that is returned in `ModelComponents` of `train_model_components`.

The parameters `MinContrastComp`, `NumLevelsComp`, `AngleStepComp`, and `OptimizationComp` can be automatically determined by passing 'auto' for the respective parameters.

All component-specific input parameters (parameter names terminate with the suffix `Comp`) must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as the number of model components contained in `ComponentTrainingID`, in which case each parameter element refers to the corresponding component in `ComponentTrainingID`.

In addition to the individual shape models, the component model also contains information about the way the single model components must be searched relative to each other using `find_component_model` in order to minimize the computation time of the search. For this, the components are represented in a tree structure. First, the component that stands at the root of this search tree (root component) is searched. Then, the remaining components are searched relative to the pose of their predecessor in the search tree.

The root component can be passed as an input parameter of `find_component_model` during the search. To what extent a model component is suited to act as root component depends on several factors. In principle, a model component that can be found in the image with a high probability should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as root component. Additionally, the computation time that is associated with the root component during the search can serve as a criterion. A ranking of the model components that is based on the latter criterion is returned in `RootRanking`. In this parameter the indices of the model components are sorted in descending order according to their associated computation time, i.e., `RootRanking[0]` contains the index of the model component that, chosen as root component, allows the fastest search. Note that the ranking returned in `RootRanking` represents only a coarse estimation. Furthermore, the calculation of the root ranking assumes that the image size as well as the value of the system parameter 'border_shape_models' are identical when calling `create_trained_component_model` and `find_component_model`.

```
Parameters

> ComponentTrainingID (input_control) ......................... component_training ~ handle
  Handle of the training result.
```
18.1. COMPONENT-BASED

- **AngleStart** (input_control) .......................... angle.rad $\sim$ real
  Smallest rotation of the component model.
  Default value: -0.39
  Suggested values: $\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$

- **AngleExtent** (input_control) .......................... angle.rad $\sim$ real
  Extent of the rotation of the component model.
  Default value: 0.79
  Suggested values: $\text{AngleExtent} \in \{6.28, 3.14, 1.57, 0.79, 0.39\}$
  Restriction: $\text{AngleExtent} \geq 0$

- **MinContrastComp** (input_control) ...................... integer(-array) $\sim$ integer / string
  Minimum contrast of the components in the search images.
  Default value: 'auto'
  Suggested values: $\text{MinContrastComp} \in \{\text{'auto'}, 10, 20, 40\}$
  Restriction: $\text{MinContrastComp} \geq 0$

- **MinScoreComp** (input_control) .......................... real(-array) $\sim$ real
  Minimum score of the instances of the components to be found.
  Default value: 0.5
  Suggested values: $\text{MinScoreComp} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: $0 \leq \text{MinScoreComp} \leq 1$

- **NumLevelsComp** (input_control) ....................... integer(-array) $\sim$ integer / string
  Maximum number of pyramid levels for the components.
  Default value: 'auto'
  List of values: $\text{NumLevelsComp} \in \{\text{'auto'}, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- **AngleStepComp** (input_control) ...................... angle.rad(-array) $\sim$ real / string
  Step length of the angles (resolution) for the components.
  Default value: 'auto'
  Suggested values: $\text{AngleStepComp} \in \{\text{'auto'}, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\}$
  Restriction: $\text{AngleStepComp} \geq 0$

- **OptimizationComp** (input_control) ................... string $\sim$ string
  Kind of optimization for the components.
  Default value: 'auto'
  List of values: $\text{OptimizationComp} \in \{\text{'auto'}, \text{'none'}, \text{'point_reduction_low'}, \text{'point_reduction_medium'}, \text{'point_reduction_high'}\}$

- **MetricComp** (input_control) .......................... string(-array) $\sim$ string
  Match metric used for the components.
  Default value: 'use_polarity'
  List of values: $\text{MetricComp} \in \{\text{'use_polarity'}, \text{'ignore_global_polarity'}, \text{'ignore_local_polarity'}, \text{'ignore_color_polarity'}\}$

- **PregenerationComp** (input_control) .................. string(-array) $\sim$ string
  Complete pregeneration of the shape models for the components if equal to 'true'.
  Default value: 'false'
  List of values: $\text{PregenerationComp} \in \{\text{'true'}, \text{'false'}\}$

- **ComponentModelID** (output_control) .................. component_model $\sim$ handle
  Handle of the component model.

- **RootRanking** (output_control) ....................... integer(-array) $\sim$ integer
  Ranking of the model components expressing the suitability to act as the root component.

---

Example

* Get the model image.
  read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
  gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
  gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
  gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images.
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, \ 
    TrainingImages, ModelComponents, 22, 60, 30, 0.65, \ 
    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \ 
    ComponentTrainingID)
* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, \ 
    0.5, 'auto', 'auto', 'none', \ 
    'use_polarity', 'false', ComponentModelID, \ 
    RootRanking)
* Find the component model in a run-time image.
read_image (SearchImage, 'search_image.tif')
find_component_model (SearchImage, ComponentModelID, RootRanking, -rad(30), \ 
    rad(60), 0.5, 0.5, 'stop_search', 'prune_branch', \ 
    'none', 0.55, 'least_squares', 0, 0.9, ModelStart, \ 
    ModelEnd, Score, RowComp, ColumnComp, AngleComp, \ 
    ScoreComp, ModelComp)

Result
If the parameters are valid, the operator create_trained_component_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Module
Matching

deserialize_component_model (  
    : : SerializedItemHandle : ComponentModelID )

Deserialize a serialized component model.
deserialize_component_model deserializes a component model, that was serialized by serialize_component_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized component model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created component model with the handle SerializedItemHandle.

**Parameters**

- **SerializedItemHandle** (input_control) 
  Handle of the serialized item.

- **ComponentModelID** (output_control) 
  Handle of the component model.

**Result**

If the parameters are valid, the operator deserialize_component_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Matching

find_component_model ( Image : : ComponentModelID, RootComponent, AngleStartRoot, AngleExtentRoot, MinScore, NumMatches, MaxOverlap, IfRootNotFound, IfComponentNotFound, PosePrediction, MinScoreComp, SubPixelComp, NumLevelsComp, GreedinessComp : ModelStart, ModelEnd, Score, RowComp, ColumnComp, AngleComp, ScoreComp, ModelComp )

Find the best matches of a component model in an image.

The operator find_component_model finds the best NumMatches instances of the component model ComponentModelID in the input image Image.

The result of the search can be visualized using get_found_component_model. Also the operator can be used to extract the component matches of a certain component model instance.

Further information about input parameters

ComponentModelID: Handle of the component model.

The model must have been created previously by calling create_trained_component_model or create_component_model, or read in using read_component_model.

RootComponent: Index of the root component.

The components of the component model ComponentModelID are represented in in a tree structure. The component that stands at the root of this search tree is the root component.

The root component is searched within the full search space, i.e., at all allowed positions and in the allowed range of orientations (see below). In contrast, the remaining components are searched relative to the pose of their predecessor in the search tree within a restricted search space that is computed from the relations (recursive search).

To what extent a model component is suited to act as root component depends on several factors. In principle, a model component that can be found in the image with a high probability, should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as root component. For the behavior in such cases, see the entry IfRootNotFound below.

A different possible criterion is the computation time that is associated with the root component during the search. A ranking of the model components that is based on the latter criterion is returned in RootRanking of the operator create_trained_component_model or create_component_model, respectively. If the complete ranking is passed in RootComponent, the first value RootComponent[0] is automatically selected as the root component.

AngleStartRoot and AngleExtentRoot: Specify the allowed angle range (in [rad]) within which the root component is searched.

If necessary, the range of rotations is clipped to the range given when the component model was created with create_trained_component_model or create_component_model, respectively. The angle range for each component can be queried with get_shape_model_params. The necessary handle of the corresponding shape model can be obtained using get_component_model_params.

MinScore: Determines what score a potential match of the component model must at least have to be regarded as an instance.

If the component model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. The value of this parameter only slightly influences the computation time. An exception is the case of IfRootNotFound set to 'select_new_root' (see below).

NumMatches: Determines the maximum number of returned instances.

If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. In case more than NumMatches instances with a score greater than
MinScore are found in the image, only the best NumMatches instances are returned. However, if all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

MaxOverlap: Determines by what fraction two instances may at most overlap, whereby this fraction is a number between 0 and 1.

In some cases, found instances only differ in the pose of one or a few components. If two instances overlap each other by more than MaxOverlap only the best instance is returned. This means, for MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 no check for overlap is performed, and hence all instances are returned. The calculation of the overlap is based on the smallest enclosing rectangles of arbitrary orientation (see smallest_rectangle2) of the found component instances.

IfRootNotFound: specifies the behavior of the operator when dealing with a missing or strongly occluded root component.

Possible values:

- 'stop_search': It is assumed that the root component is always found in the image. Consequently, for instances for which the root component could not be found the search for the remaining components is not continued.
- 'select_new_root': Different components are successively chosen as the root component and searched within the full search space. The order in which the selection of the root component is performed corresponds to the order passed in RootRanking. The poses of the found instances of all root components are then used to start the recursive search for the remaining components. Hence, it is possible to find instances even if the original root component is not found. However, the computation time of the search increases significantly in comparison to the search when choosing 'stop_search'. This is especially the case for small values of MinScore, as more root components must be searched. If during the search more root components are needed as given in RootComponent, the root components are completed by the automatically computed order (see create_trained_component_model or create_component_model).

IfComponentNotFound: Specifies how components are searched when the predecessor component was not found (e.g., because she is missing or strongly occluded).

Possible values:

- 'prune_branch': Such components are not searched at all and are also treated as 'not found'.
- 'search_from_upper': Such components are searched relative to the pose of the predecessor component of the predecessor component.
- 'search_from_best': Such components are searched relative to the pose of the already found component from which the relative search can be performed with minimum computational effort.

PosePrediction: Determines whether the pose of not found components should be estimated.

Possible values:

- 'none': Only the poses of the found components are returned.
- 'from_neighbors': The poses of not found components are estimated and returned with a score of ScoreComp = 0.0. The pose estimation is based on the poses of the found neighboring components in the search tree.
- 'from_all': The poses of not found components are estimated and returned with a score of ScoreComp = 0.0. The pose estimation is based on the poses of all found components.

MinScoreComp: Minimal necessary score of the components for the instances to be found.

This parameter has the same meaning as MinScore in find_shape_model. Settable is either one element or the same number of elements as model components in ComponentModelID. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in ComponentModelID.

SubPixelComp: Determines whether the extraction shall be done subpixel precise and in the given case the maximal allowed object deformation in pixels.

This parameter has the same meaning as SubPixel in find_shape_model. Therefore the maximal allowed object deformation has to be given as integer in the same string. Settable is either one element or the same number of elements as model components in ComponentModelID. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in ComponentModelID.

Example: ['least_squares', 'max_deformation 2'].

HALCON 20.11.0.0
**NumLevelsComp:** Determine the pyramid levels for the components used in the matching.

This parameter has the same meaning as **NumLevels** in `find_shape_model`.

It determines the number of pyramid levels for the components to be used in the matching. Settable is either one element or the same number of elements as model components in **ComponentModelID**. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in **ComponentModelID**.

Optional, one can set value pairs for this parameter: In this case, the first value still determines the number of pyramid levels to be used. The second value specifies the lowest pyramid level, to which the found matches are tracked. In doing so, one can set either a single value pair or a value pair for each model component in **ComponentModelID**. If different value pairs should be used for different components, they must be specified in the same tuple. In case **ComponentModelID** contains exactly two components and in **NumLevelsComp** two values are set, these values are interpreted as different number of pyramid levels to be used and not as a value pair.

*Example:* **ComponentModelID** contains two components, for which different pyramid levels shall be considered. For the first component 5 levels up to the level 2 shall be used. For the second component 4 levels up to the level 1 shall be used. In this case is **NumLevelsComp** = [5, 2, 4, 1].

**GreedinessComp:** “Greediness” of the search heuristic for the components: value from 0 to 1. Thereby 0 means: safe but slow, 1: fast but matches may be missed.

This parameter has the same meaning as **Greediness** in `find_shape_model`.

Settable is either one element or the same number of elements as model components in **ComponentModelID**. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in **ComponentModelID**.

Further information about output parameters

**ModelStart** and **ModelEnd:** Return the first and last index and therewith the index range of all component matches associated to the same instance of the component model.

The component matches corresponding to the first found instance of the component model are given by the interval of indices **[ModelStart[0], ModelEnd[0]]**. Thereby the indices refer to the values of the parameters **RowComp, ColumnComp, AngleComp, ScoreComp**, and **ModelComp**.

*Example:* The component model consists for three components. Two instances have been found on the image, where for one instance only two components (component 0 and component 2) could be found. Then the returned parameters could look like this:

```
RowComp = [100, 200, 300, 150, 250]    ModelStart = [0, 3]
AngleComp = [0, 0.1, -0.2, 0.1, 0.2]    ModelComp = [0, 1, 2, 0, 2]
ScoreComp = [1, 1, 1, 1, 1]             Score = [1, 1]
```

From the right column it is visible, that in the left column:

- Values with index 0 to 2 correspond to the components 0 to 2 of instance 1.
- Values with index 3 to 4 correspond to the components 0 and 2 of instance 2.

**Score:** Score of the found instances of the component model.

**Score** contains the weighted mean of the component scores, the values in **ScoreComp**. The weighting is performed according to the number of model points within the respective component.

**RowComp, ColumnComp, and AngleComp:** The position (**RowComp, ColumnComp**) and rotation (**AngleComp**) of the model components of all found component model instances.

The coordinates **RowComp** and **ColumnComp** are the coordinates of the component origin (reference point) in the search image. The component origin depends on the model creation:

- with `create_trained_component_model` by training: The component origin is the center of gravity of the respective returned contour region in **ModelComponents** of the operator `train_model_components`.
- with `create_component_model` manually: The component origin is the center of gravity of the corresponding passed component region **ComponentRegion** of the operator `create_component_model`.
Since the relations between the components in ComponentModelID refer to this reference point, the origin of the components must not be modified by using set_shape_model_origin.

**ScoreComp**: Score of each found component instance.

The score is a number between 0 and 1, and is an approximate measure of how much of the component is visible in the image. If, for example, half of the component is occluded, the score cannot exceed 0.5.

**ModelComp**: Index of the found component.

The tuple contains the indices of the respective model components (see create_component_model and train_model_components, respectively). By this the values in RowComp, ColumnComp, AngleComp, and ScoreComp can be associated to the different model components. See also the example given for ModelStart and ModelEnd.

**Information concerning the search**

Internally, the shape-based matching is used for the component-based matching in order to search the individual components (see find_shape_model).

The domain of the Image determines the search space for the reference point, i.e., the allowed positions, of the root component.

Usually the component model is searched only within those points of the image domain in which the model fits completely into the image. This means that the components will not be found if they extend beyond the borders of the image, even if they would achieve a score greater than MinScoreComp (see above).

Note that, if for a certain pyramid level the component model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with set_system ('border_shape_models','true'), which will cause components that extend beyond the image border to be found if they achieve a score greater than MinScoreComp. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that this mode increases the runtime of the search.

Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., dilation_circle.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.

**Recommendations**

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a subpixel extraction that applies a least-squares adjustment. If the subpixel extraction and/or the maximum object deformation is specified separately for each component, for each component in ComponentModelID exactly one value for the subpixel extraction must be passed in SubPixelComp. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain component no value for the maximum object deformation is passed, the component is searched without taking deformations into account. Further details can be found in the documentation of find_shape_models.

---

**Parameters**

- **Image** (input_object) : (multichannel-)image \(\sim\) object : byte / uint2
  Input image in which the component model should be found.

- **ComponentModelID** (input_control) : component_model \(\sim\) handle
  Handle of the component model.

- **RootComponent** (input_control) : integer(-array) \(\sim\) integer
  Index of the root component.

**Suggested values**: RootComponent \(\in\) {0, 1, 2, 3, 4, 5, 6, 7, 8}

**HALCON/HDevelop Reference Manual, 2020-11-10**
18.1. COMPONENT-BASED

- **GreedinessComp** (input_control) - real(-array)  \( \sim \) real
  "Greediness" of the search heuristic for the components (0: safe but slow; 1: fast but matches may be missed).
  **Default value:** 0.9
  **Suggested values:** GreedinessComp ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  **Minimum increment:** 0.01
  **Recommended increment:** 0.05
  **Restriction:** 0 <= GreedinessComp && GreedinessComp <= 1

- **ModelStart** (output_control) - integer(-array)  \( \sim \) integer
  Start index of each found instance of the component model in the tuples describing the component matches.

- **ModelEnd** (output_control) - integer(-array)  \( \sim \) integer
  End index of each found instance of the component model in the tuples describing the component matches.

- **Score** (output_control) - real(-array)  \( \sim \) real
  Score of the found instances of the component model.

- **RowComp** (output_control) - point.y(-array)  \( \sim \) real
  Row coordinate of the found component matches.

- **ColumnComp** (output_control) - point.x(-array)  \( \sim \) real
  Column coordinate of the found component matches.

- **AngleComp** (output_control) - angle.rad(-array)  \( \sim \) real
  Rotation angle of the found component matches.

- **ScoreComp** (output_control) - real(-array)  \( \sim \) real
  Score of the found component matches.

- **ModelComp** (output_control) - integer(-array)  \( \sim \) integer
  Index of the found components.

**Result**

If the parameter values are correct, the operator find_component_model returns the value 2 (H_MSG_TRUE). If the input is empty (no input image available) the behavior can be set via set_system (‘no_object_result’,<Result>). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

<table>
<thead>
<tr>
<th>gen_initial_components</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelImage : InitialComponents : ContrastLow, ContrastHigh, MinSize, Mode, GenericName, GenericValue : )</td>
</tr>
</tbody>
</table>

Extract the initial components of a component model.

In general, there are two possibilities to use gen_initial_components. The first possibility should be chosen if the components of the component model are not known. Then gen_initial_components
automatically extracts the initial components of a component model from a model image. The second possibility can be chosen if the components of the component model are approximately known. Then \texttt{gen\_initial\_components} can be used to find suitable parameter values for the model feature extraction in \texttt{train\_model\_components} and \texttt{create\_component\_model}. Hence, the second possibility is comparable to the function of \texttt{inspect\_shape\_model} within the shape-based matching.

When using the first possibility, \texttt{gen\_initial\_components} extracts the initial components of a component model from a model image \texttt{ModelImage}. As already mentioned, this is especially useful if the components of the component model are not known. In this case, the resulting initial components can be used to automatically train the component model with \texttt{train\_model\_components}, which extracts the (final) model components and the relations between them. \texttt{gen\_initial\_components} returns the initial components in a region object tuple \texttt{InitialComponents} that contains a representation for each initial component in form of contour regions.

For the automatic determination of the initial components, the domain of the model image \texttt{ModelImage} must contain the entire compound object including all components. \texttt{Mode} specifies the method used for the automatic computation. Currently, only the mode ‘\textit{connection}’ is available. In this mode the automatic computation is performed in two steps: In the first step, features are extracted using the parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize}. These three parameters define the contours of which the initial components should consist and should be chosen such that only the significant features of the model image are contained in the initial components. \texttt{ContrastLow} and \texttt{ContrastHigh} specify the gray value contrast of the points that should be contained in the initial components. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. The model image is segmented using a method similar to the hysteresis threshold method used in \texttt{edges\_image}. Here, \texttt{ContrastLow} determines the lower threshold, while \texttt{ContrastHigh} determines the upper threshold. If the same value is passed for \texttt{ContrastLow} and \texttt{ContrastHigh} a simple thresholding operation is performed. For more information about the hysteresis threshold method, see \texttt{hysteresis\_threshold}. \texttt{MinSize} can be used to select only significant features for the initial components based on the size of the connected contour regions, i.e., connected contour regions with fewer than \texttt{MinSize} points are suppressed.

The resulting connected contour regions are iteratively merged in the second step. For this, two contour regions are merged if the distance between both regions is smaller than a certain threshold (see below). Finally, the merged regions are returned in \texttt{InitialComponents} and can be used to train the component model by passing them to \texttt{train\_model\_components}.

To control the internal image processing, the parameters \texttt{GenericName} and \texttt{GenericValue} are used. This is done by passing the names of the control parameters to be changed in \texttt{GenericName} as a list of strings. In \texttt{GenericValue} the values are passed at the corresponding index positions.

Normally, none of the values needs to be changed. A change should only be applied in case of unsatisfying results of the automatic determination of the initial components. The two parameters that can be changed are ‘\textit{merge\_distance}’ and ‘\textit{merge\_fraction}’; both are used during the iterative merging of contour regions (see above). First, the fraction of contour pixels of one contour region that at most have a distance of ‘\textit{merge\_distance}’ from another contour region is computed. If this fraction exceeds the value that is passed in ‘\textit{merge\_fraction}’ the two contour regions are merged. Consequently, the higher ‘\textit{merge\_distance}’ and the lower ‘\textit{merge\_fraction}’ is chosen the more contour regions are merged. The default value of ‘\textit{merge\_distance}’ is 5 and the default value of ‘\textit{merge\_fraction}’ is 0.5 (corresponds to 50 percent).

When using the second possibility, i.e., the components of the component model are approximately known, the training by using \texttt{train\_model\_components} can be performed without previously executing \texttt{gen\_initial\_components}. If this is desired, the initial components can be specified by the user and directly passed to \texttt{train\_model\_components}. Furthermore, if the components as well as the relative movements (relations) of the components are known, \texttt{gen\_initial\_components} as well as \texttt{train\_model\_components} need not be executed. In fact, by immediately passing the components as well as the relations to \texttt{create\_component\_model}, the component model can be created without any training. In both cases, however, \texttt{gen\_initial\_components} can be used to evaluate the effect of the feature extraction parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize} of \texttt{train\_model\_components} and \texttt{create\_component\_model}, and hence to find suitable parameter values for a certain application.

For this, the image regions for the (initial) components must be explicitly given, i.e., for each (initial) component a separate image from which the (initial) component should be created is passed. In this case, \texttt{ModelImage} contains multiple image objects. The domain of each image object is used as the region of interest for calculating the corresponding (initial) component. The image matrix of all image objects in the tuple must be identical, i.e., \texttt{ModelImage} cannot be constructed in an arbitrary manner using \texttt{concat\_obj}, but must be created from the same image using \texttt{add\_channels} or equivalent calls. If this is not the case, an error message is returned. If
the parameters $\text{ContrastLow}$, $\text{ContrastHigh}$, or $\text{MinSize}$ only contain one element, this value is applied to the creation of all (initial) components. In contrast, if different values for different (initial) components should be used, tuples of values can be passed for these three parameters. In this case, the tuples must have a length that corresponds to the number of (initial) components, i.e., the number of image objects in $\text{ModelImage}$. The contour regions of the (initial) components are returned in $\text{InitialComponents}$.

Thus, the second possibility is equivalent to the function of $\text{inspect_shape_model}$ within the shape-based matching. However, in contrast to $\text{inspect_shape_model}$, $\text{gen_initial_components}$ does not return the contour regions on multiple image pyramid levels. Therefore, if the number of pyramid levels to be used should be chosen manually, preferably $\text{inspect_shape_model}$ should be called individually for each (initial) component.

For both described possibilities the parameters $\text{ContrastLow}$, $\text{ContrastHigh}$, and $\text{MinSize}$ can be automatically determined. If both hysteresis threshold should be automatically determined, both $\text{ContrastLow}$ and $\text{ContrastHigh}$ must be set to ‘auto’. In contrast, if only one threshold value should be determined, $\text{ContrastLow}$ must be set to ‘auto’ while $\text{ContrastHigh}$ must be set to an arbitrary value different from ‘auto’.

If the input image $\text{ModelImage}$ has one channel the representation of the model is created with the method that is used in $\text{create_component_model}$ or $\text{create_trained_component_model}$ for the metrics ‘use_polarity’, ‘ignore_global_polarity’, and ‘ignore_local_polarity’. If the input image has more than one channel the representation is created with the method that is used for the metric ‘ignore_color_polarity’.

---

**Parameters**

- **$\text{ModelImage}$**: (multichannel-)image(-array) $\sim$ object : byte / uint2  
  Input image from which the initial components should be extracted.

- **$\text{InitialComponents}$**: (output_object) region-array $\sim$ object  
  Contour regions of initial components.

- **$\text{ContrastLow}$**: (input_control) integer(-array) $\sim$ integer / string  
  Lower hysteresis threshold for the contrast of the initial components in the image.  
  Default value: ‘auto’  
  Suggested values: $\text{ContrastLow} \in \{ \text{‘auto’}, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160 \}$  
  Restriction: $\text{ContrastLow} > 0$

- **$\text{ContrastHigh}$**: (input_control) integer(-array) $\sim$ integer / string  
  Upper hysteresis threshold for the contrast of the initial components in the image.  
  Default value: ‘auto’  
  Suggested values: $\text{ContrastHigh} \in \{ \text{‘auto’}, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160 \}$  
  Restriction: $\text{ContrastHigh} > 0$ && $\text{ContrastHigh} \geq \text{ContrastLow}$

- **$\text{MinSize}$**: (input_control) integer(-array) $\sim$ integer / string  
  Minimum size of the initial components.  
  Default value: ‘auto’  
  Suggested values: $\text{MinSize} \in \{ \text{‘auto’}, 0, 5, 10, 20, 30, 40 \}$  
  Restriction: $\text{MinSize} \geq 0$

- **$\text{Mode}$**: (input_control) string $\sim$ string  
  Type of automatic segmentation.  
  Default value: ‘connection’  
  List of values: $\text{Mode} \in \{ \text{‘connection’} \}$

- **$\text{GenericName}$**: (input_control) string(-array) $\sim$ string  
  Names of optional control parameters.  
  Default value: []  
  List of values: $\text{GenericName} \in \{ \text{‘merge_distance’}, \text{‘merge_fraction’} \}$

- **$\text{GenericValue}$**: (input_control) number(-array) $\sim$ real / integer  
  Values of optional control parameters.  
  Default value: []

---

**Example**

* First example that shows the use of gen_initial_components to automatically extract the initial components from a model image.

* Get the model image.
read_image (Image, 'model_image.tif')

* Define the entire model region.
gen_rectangle1 (ModelRegion, 119, 106, 330, 537)
reduce_domain (Image, ModelRegion, ModelImage)

* Automatically generate the initial components.
gen_initial_components (ModelImage, InitialComponents, 40, 40, 20, 
  'connection', [], [])

* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponents, TrainingImages, 
  ModelComponents, 40, 40, 20, 0.85, 0, 0, rad(15), 
  'speed', 'rigidity', 0.2, 0.5, ComponentTrainingID)

* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, 
  0.8, 'auto', 'auto', 'none', 
  'use_polarity', 'false', ComponentModelID, 
  RootRanking)

* Second example that shows the use of gen_initial_components to evaluate
  * the effect of the feature extraction parameters.

* Get the model image.
read_image (ModelImage, 'model_image.tif')

* Define the regions for the components.
gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)
gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)
gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)
concat_obj (ComponentRegions, Rectangle2, ComponentRegions)
concat_obj (ComponentRegions, Rectangle3, ComponentRegions)
add_channels (ComponentRegions, ModelImage, ModelImageReduced)
gen_initial_components (ModelImageReduced, InitialComponents, 15, 40, 15, 
  'connection', [], [])

* Create the component model by explicitly specifying the relations.
create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, 
  rad(360), 15, 40, 15, 10, 0.8, 'auto', 'auto', 
  'none', 'use_polarity', 'false', ComponentModelID, 
  RootRanking)

Result
If the parameter values are correct, the operator gen_initial_components returns the value 2
(H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system
('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

Possible Successors

Alternatives

inspect_shape_model

Module

Matching
Return the parameters of a component model.

The operator `get_component_model_params` returns the parameters of the component model `ComponentModelID`. In particular, this output can be used to check the parameters `RootRanking` and `MinScoreComp` after reading the component model with `read_component_model`. Additionally, the operator returns the shape model IDs `ShapeModelIDs` of the model components. The order of the returned shape model IDs corresponds to the indices of the components within the component model `ComponentModelID`. The IDs can be used to query their shape model parameters with `get_shape_model_params`.

```plaintext
get_component_model_params ( : : ComponentModelID : MinScoreComp, RootRanking, ShapeModelIDs )
```

**Parameters**

- `ComponentModelID` (input_control) ...................... `handle` Handle of the component model.
- `MinScoreComp` (output_control) .......................... `real(-array)` `real` Minimum score of the instances of the components to be found.
- `RootRanking` (output_control) .......................... `integer(-array)` `integer` Ranking of the model components expressing their suitability to act as root component.
- `ShapeModelIDs` (output_control) ...................... `shape_model(-array)` `handle` Handles of the shape models of the individual model components.

**Example**

```plaintext
read_component_model ('pliers.cpm', ComponentModelID)
get_component_model_params (ComponentModelID, MinScoreComp, RootRanking, \ ShapeModelIDs)
for i := 0 to |ShapeModelIDs|-1 by 1
    get_shape_model_params (ShapeModelIDs[i], NumLevels, AngleStart, \ AngleExtent, AngleStep, ScaleMin, ScaleMax, \ ScaleStep, Metric, MinContrast)
endfor
```

**Result**

If the handle of the component model is valid, the operator `get_component_model_params` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Module**

`Matching`

---

`get_component_model_tree` ( : Tree, Relations : ComponentModelID, RootComponent, Image : StartNode, EndNode, Row, Column, Phi, Length1, Length2, AngleStart, AngleExtent )

Return the search tree of a component model.
get_component_model_tree returns the search tree Tree and the associated relations Relations of the component model that is passed in ComponentModelID in form of regions as well as in numerical form. get_component_model_tree is particularly useful in order to visualize the search order of the components, which was automatically computed in create_trained_component_model or create_component_model.

Because the search tree depends on the selected root component, the root component must be passed in RootComponent. The nodes in the tree Tree represent the model components, the connecting lines between the nodes indicate which components are searched relative to each other. The position of the nodes corresponds to the position of the components in the model image (if Image = 'model_image' or Image = 0) or in a training image (if Image ≥ 1). In the latter case, the component model must have been created based on a component training result with create_trained_component_model.

Let n be the number of components in ComponentModelID. The region object tuple Relations of length n is designed as follows: For each component a separate region is returned. The positions of all components in the image are represented by circles with a radius of 3 pixels. For each component other than the root component RootComponent, additionally the position relation and the orientation relation relative to the predecessor component in the search tree are represented. The position relation is represented by a rectangle, the orientation relation is represented by a circle sector with a radius of 30 pixels. The center of the circle is placed at the mean relative position of the component. The rectangle describes the movement of the reference point of the respective component relative to the pose of its predecessor component, the circle sector describes the variation of the relative orientation. A relative orientation of 0 corresponds to the relative orientation of both components in the model image.

In addition to the regions, the search tree as well as the associated relations are also returned in numerical form. The search tree is described by the two tuples StartNode and EndNode, both of length n, which contain the start and the end node of all arcs in the tree. The nodes contain the indices of the components. This means that during the search the component that is described by the end node is searched relative to the pose of the component that is described by the start node (predecessor component). Since the root component is not searched relative to any other component, and hence does not have a predecessor component, the associated start node is set to -1. The relations are returned in Row, Column, Phi, Length1, Length2, AngleStart, and AngleExtent. These parameters are tuples of length n, and contain the relations of all components relative to their associated predecessor component, where the order of the values within the tuples is determined by the index of the corresponding component. The position relation is described by the parameters of the corresponding rectangle Row, Column, Phi, Length1, and Length2 (see gen_rectangle2). The orientation relation is described by the starting angle AngleStart and the angle extent AngleExtent.

For the root component as well as for components that do not have a predecessor in the current image or that have not been found in the current image, an empty region is returned and the corresponding values of the seven parameters are set to 0.

---

**Parameters**

- **Tree** (output_object) ..........................region  ∼ object
  Search tree.

- **Relations** (output_object) ..........................region-array  ∼ object
  Relations of components that are connected in the search tree.

- **ComponentModelID** (input_control) ..........................component_model  ∼ handle
  Handle of the component model.

- **RootComponent** (input_control) ..........................integer(-array)  ∼ integer
  Index of the root component.

**Suggested values:** RootComponent ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8}

- **Image** (input_control) ..........................string  ∼ string / integer
  Image for which the tree is to be returned.

**Default value:** 'model_image'

**Suggested values:** Image ∈ ['model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8]

- **StartNode** (output_control) ..........................integer(-array)  ∼ integer
  Component index of the start node of an arc in the search tree.

- **EndNode** (output_control) ..........................integer(-array)  ∼ integer
  Component index of the end node of an arc in the search tree.

- **Row** (output_control) ..........................rectangle2.center.y(-array)  ∼ real
  Row coordinate of the center of the rectangle representing the relation.
18.1. COMPONENT-BASED

- **Column** (output_control) \( \rightarrow \text{real} \)
  Column index of the center of the rectangle representing the relation.

- **Phi** (output_control) \( \rightarrow \text{real} \)
  Orientation of the rectangle representing the relation (radians).
  **Assertion:** \(- \pi / 2 < \Phi \&\& \Phi <= \pi / 2\)

- **Length1** (output_control) \( \rightarrow \text{real} \)
  First radius (half length) of the rectangle representing the relation.
  **Assertion:** \( \text{Length1} >= 0.0\)

- **Length2** (output_control) \( \rightarrow \text{real} \)
  Second radius (half width) of the rectangle representing the relation.
  **Assertion:** \( \text{Length2} >= 0.0 \&\& \text{Length2} <= \text{Length1}\)

- **AngleStart** (output_control) \( \rightarrow \text{real} \)
  Smallest relative orientation angle.

- **AngleExtent** (output_control) \( \rightarrow \text{real} \)
  Extent of the relative orientation angle.

**Example**

* Read the model image.
  \text{read\_image (ModelImage, 'model\_image.tif')}*

* Describe the model components.
  \text{gen\_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)}
  \text{gen\_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)}
  \text{gen\_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)}
  \text{concat\_obj (ComponentRegions, Rectangle2, ComponentRegions)}
  \text{concat\_obj (ComponentRegions, Rectangle3, ComponentRegions)}

* Create the component model.
  \text{create\_component\_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \}
  \text{rad(360), 15, 40, 15, 10, 0.8, 0, 0, 'none', \}
  \text{'use\_polarity', 'true', ComponentModelID, \}
  \text{RootRanking)}

* Get the component model tree.
  \text{get\_component\_model\_tree (Tree, Relations, ComponentModelID, RootRanking, \}
  \text{'model\_image', StartNode, EndNode, Row, Column, \}
  \text{Phi, Length1, Length2, AngleStart, AngleExtent)}

\text{dev\_set\_colored (12)}
\text{dev\_display (ModelImage)}
\text{dev\_display (Tree)}
\text{dev\_display (Relations)}

**Result**

If the parameters are valid, the operator \text{get\_component\_model\_tree} returns the value 2 (H_MSG_TRUE).
If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching
get_component_relations ( : Relations : ComponentTrainingID, ReferenceComponent, Image : Row, Column, Phi, Length1, Length2, AngleStart, AngleExtent )

Return the relations between the model components that are contained in a training result.

get_component_relations returns the relations between model components after training them with train_model_components. With the parameter ReferenceComponent, you can select a reference component. get_component_relations then returns the relations between the reference component and all other components in the model image (if Image = 'model_image' or Image = 0) or in a training image (if Image ≥ 1). In order to obtain the relations in the ith training image, Image must be set to i. The result of the training returned by train_model_components must be passed in ComponentTrainingID. ReferenceComponent describes the index of the reference component and must be within the range of 0 and n-1, if n is the number of model components (see train_model_components).

The relations are returned in form of regions in Relations as well as in form of numerical values in Row, Column, Phi, Length1, Length2, AngleStart, and AngleExtent.

The region object tuple Relations is designed as follows. For each component a separate region is returned. Consequently, Relations contains n regions, where the order of the regions within the tuple is determined by the index of the corresponding components. The positions of all components in the image are represented by circles with a radius of 3 pixels. For each component other than the reference component ReferenceComponent, additionally the position relation and the orientation relation relative to the reference component are represented. The position relation is represented by a rectangle and the orientation relation is represented by a circle sector with a radius of 30 pixels. The center of the circle is placed at the mean relative position of the component. The rectangle describes the movement of the reference point of the respective component relative to the pose of the reference component, while the circle sector describes the variation of the relative orientation (see train_model_components). A relative orientation of 0 corresponds to the relative orientation of both components in the model image. If both components appear in the same relative orientation in all images, the circle sector consequently degenerates to a straight line.

In addition to the region object tuple Relations, the relations are also returned in form of numerical values in Row, Column, Phi, Length1, Length2, AngleStart, and AngleExtent. These parameters are tuples of length n and contain the relations of all components relative to the reference component, where the order of the values within the tuples is determined by the index of the corresponding component. The position relation is described by the parameters of the corresponding rectangle Row, Column, Phi, Length1, and Length2 (see gen_rectangle2). The orientation relation is described by the starting angle AngleStart and the angle extent AngleExtent. For the reference component only the position within the image is returned in Row and Column. All other values are set to 0.

If the reference component has not been found in the current image, an array of empty regions is returned and the corresponding parameter values are set to 0.

The operator get_component_relations is particularly useful in order to visualize the result of the training that was performed with train_model_components. With this, it is possible to evaluate the variations that are contained in the training images. Sometimes it might be reasonable to restart the training with train_model_components while using a different set of training images.

Parameters

- Relations (output_object) .................................................. region(-array) 〜 object
  Region representation of the relations.
- ComponentTrainingID (input_control) .................................. component_training 〜 handle
  Handle of the training result.
- ReferenceComponent (input_control) .................................... integer 〜 integer
  Index of reference component.
- Image (input_control) ...................................................... string 〜 string / integer
  Image for which the component relations are to be returned.
  Default value: 'model_image'
  Suggested values: Image ∈ {'model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8}
- Row (output_control) ...................................................... rectangle2.center.y(-array) 〜 real
  Row coordinate of the center of the rectangle representing the relation.
Component-based

Column (output_control) ........................................ rectangle2.center.x(-array) \rightarrow real
Column index of the center of the rectangle representing the relation.

Phi (output_control) ........................................ rectangle2.angle.rad(-array) \rightarrow real
Orientation of the rectangle representing the relation (radians).

Assertion: \(-\pi / 2 < \Phi \&\& \Phi \leq \pi / 2\)

Length1 (output_control) ........................................ rectangle2.hwidth(-array) \rightarrow real
First radius (half length) of the rectangle representing the relation.

Assertion: Length1 \geq 0.0

Length2 (output_control) ........................................ rectangle2.hheight(-array) \rightarrow real
Second radius (half width) of the rectangle representing the relation.

Assertion: Length2 \geq 0.0 \&\& Length2 \leq Length1

AngleStart (output_control) .................................. angle.rad(-array) \rightarrow real
Smallest relative orientation angle.

AngleExtent (output_control) ................................. angle.rad(-array) \rightarrow real
Extent of the relative orientation angles.

Result

If the handle of the training result is valid, the operator get_component_relations returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_rectangle2

Module

get_found_component_model ( : FoundComponents : ComponentModelID,
ModelStart, ModelEnd, RowComp, ColumnComp, AngleComp, ScoreComp,
ModelComp, ModelMatch, MarkOrientation : RowCompInst,
ColumnCompInst, AngleCompInst, ScoreCompInst )

Return the components of a found instance of a component model.

get_found_component_model returns the components of a found instance of the component model ComponentModelID in form of contour regions in FoundComponents as well as in numerical form.

The operator get_found_component_model is particularly useful in order to visualize the matches that have been obtained by find_component_model.

The pose of the returned components corresponds to their pose in the search image as returned by find_component_model. Hence, the parameters ModelStart, ModelEnd, RowComp, ColumnComp, AngleComp, ScoreComp, and ModelComp must be passed to get_found_component_model as they have been returned by find_component_model. In ModelMatch the index of the found instance of the component model must be passed. Consequently, ModelMatch must lie within the range between 0 and \(m-1\), where \(m\) is the number of elements in ModelStart and ModelEnd, and hence corresponds to the number of found model instances. For example, if the best match should be returned, ModelMatch should be set to 0.

When dealing with rotationally symmetric components, one may wish to mark the current orientation of the found component. This can be achieved by setting MarkOrientation to 'true'. In this case, the contour region of each component is complemented by an arrow at its reference point that points in the reference direction.
The reference direction of a component is based on the orientation of the component in the model image (see `train_model_components` or `create_component_model`) and is represented by an arrow that starts at the reference point and points to the right in the horizontal direction.

For convenience, the pose parameters as well as the score of each component of the found model instance are additionally returned in numerical form in `RowCompInst`, `ColumnCompInst`, `AngleCompInst`, and `ScoreCompInst`. The four tuples are always of length $n$, where $n$ is the number of components in the component model `ComponentModelID`. If a component could not be found during the search, an empty region is passed in the corresponding element of `FoundComponents` and the value of the corresponding element in `RowCompInst`, `ColumnCompInst`, `AngleCompInst`, and `ScoreCompInst` is set to 0.

Example

* Read a component model from file.
  `read_component_model ('pliers.cpm', ComponentModelID)`
* Find the component model in a run-time image.
  `read_image (SearchImage, 'search_image.tif')`
  `find_component_model (SearchImage, ComponentModelID, RootRanking, 0, \n  rad(360), 0.5, 0.5, 'stop_search', 'prune_branch', \n  'none', 0.8, 'least_squares', 0, 0.8, ModelStart, \n  ModelEnd, Score, RowComp, ColumnComp, AngleComp, \n  ScoreComp, ModelComp)`
* Visualize the found instances.
  `for i := 0 to |ModelStart|-1 by 1`
get_found_component_model (FoundComponents, ComponentModelID, \
    ModelStart, ModelEnd, RowComp, ColumnComp, \ 
    AngleComp, ScoreComp, ModelComp, i, 'false', \ 
    RowCompInst, ColumnCompInst, AngleCompInst, \ 
    ScoreCompInst)

dev_display (FoundComponents)
endfor

Result

If the parameters are valid, the operator get_found_component_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

train_model_components, create_component_model

Module

Matching

get_training_components (  
    : TrainingComponents : ComponentTrainingID, Components, Image, 
    MarkOrientation : Row, Column, Angle, Score )

Return the initial or model components in a certain image.

get_training_components returns all initial components (if Components = 'initial_components') or all model components (if Components = 'model_components') in TrainingComponents in form of contour regions as well as in numerical form. Alternatively, by directly passing the index of an initial component, all found poses of that initial component (i.e., the poses before solving the ambiguities in train_model_components) are returned.

The pose of the returned components corresponds to their pose in the model image (if Image = 'model_image' or Image = 0) or in a training image (if Image ≥ 1). In order to obtain the components in the pose at which they were found in the i-th training image, Image must be set to i. Furthermore, when dealing with rotationally symmetric components, one may wish to mark the current orientation of the found component. This can be achieved by setting MarkOrientation to 'true'. In this case, the contour region of each component is complemented by an arrow at its reference point pointing in the reference direction. The reference direction of a component is based on the orientation of the component in the model image and is represented by an arrow that starts at the reference point and points to the right in the horizontal direction.

In addition to the contour regions, the pose and the score of all found components is returned in Row, Column, Angle, and Score (see find_shape_model). If Components was set to 'initial_components' or 'model_components', the tuples TrainingComponents, Row, Column, Angle, and Score always contain the same number of elements as initial components or model components contained in ComponentTrainingID, respectively. If one component was not found in the image, an empty region is returned in the corresponding element of TrainingComponents and the elements of the four output control parameters are set to the value 0. In contrast, if the index of an initial component is passed in Components, these tuples contain as many elements as matches of the corresponding initial component were found in the image.

The operator get_training_components is particularly useful in order to visualize the result of the training ComponentTrainingID, which was performed with train_model_components. With this, it is possible to evaluate the suitability of the training images or to inspect the influence of the parameters of train_model_components. Sometimes it might be reasonable to restart the training with train_model_components using a different set of training images or after adjusting the parameters.
### Parameters

- **TrainingComponents** (output_object) ............................................. region(-array) $\sim$ object
  Contour regions of the initial components or of the model components.

- **ComponentTrainingID** (input_control) .................................. component_training $\sim$ handle
  Handle of the training result.

- **Components** (input_control) ............................................. string $\sim$ string / integer
  Type of returned components or index of an initial component.
  **Default value:** 'model_components'
  **Suggested values:** Components $\in$ ['model_components', 'initial_components', 0, 1, 2, 3, 4, 5]

- **Image** (input_control) ............................................. string $\sim$ string / integer
  Image for which the components are to be returned.
  **Default value:** 'model_image'
  **Suggested values:** Image $\in$ ['model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8]

- **MarkOrientation** (input_control) ...................................... string $\sim$ string
  Mark the orientation of the components.
  **Default value:** 'false'
  **List of values:** MarkOrientation $\in$ {'true', 'false'}

- **Row** (output_control) .................................................. point.y(-array) $\sim$ real
  Row coordinate of the found instances of all initial components or model components.

- **Column** (output_control) ................................................ point.x(-array) $\sim$ real
  Column coordinate of the found instances of all initial components or model components.

- **Angle** (output_control) ............................................... angle.rad(-array) $\sim$ real
  Rotation angle of the found instances of all components.

- **Score** (output_control) ............................................... real(-array) $\sim$ real
  Score of the found instances of all components.

### Example

* Get the model image.
  read_image (ModelImage, 'model_image.tif')

* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
  gen_rectangle2 (InitialComponentRegions, 298, 363, 1.17, 162, 34)
  gen_rectangle2 (InitialComponentRegions, 63, 444, -0.26, 50, 27)
  gen_rectangle2 (InitialComponentRegions, 120, 473, 0, 33, 20)
  concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)

* Get the training images.
  gen_empty_obj (TrainingImages)
  for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
  endfor

* Extract the model components and train the relations.
  train_model_components (ModelImage, InitialComponentRegions, \ TrainingImages, ModelComponents, 22, 60, 30, 0.6, \ 0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \ ComponentTrainingID)

* Visualize the result of the training.
  count_obj (InitialComponentRegions, NumInitComp)
  count_obj (TrainingImages, NumTrainings)
  for i := 1 to NumTrainings by 1
    select_obj (TrainingImages, TrainingImage, i)
    for j := 0 to NumInitComp-1 by 1
      * Visualize the ambiguous poses of each initial component.
        get_training_components (TrainingComponents, ComponentTrainingID, \ j, i, 'false', Row, Column, Angle, Score)
endfor
* Visualize the final poses of the initial components.
get_training_components (TrainingComponents, ComponentTrainingID, 
   'initial_components', i, 'false', 
   Row, Column, Angle, Score)
* Visualize the final poses of the model components.
get_training_components (TrainingComponents, ComponentTrainingID, 
   'model_components', i, 'false', 
   Row, Column, Angle, Score)
endfor

Result
If the handle of the training result is valid, the operator get_training_components returns the value 2
(H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

inspect_clustered_components ( 
   : ModelComponents : ComponentTrainingID, AmbiguityCriterion, 
   MaxContourOverlap, ClusterThreshold : )

Inspect the rigid model components obtained from the training.

inspect_clustered_components creates a representation of the rigid model components based on the
training result ComponentTrainingID in form of contour regions. The resulting rigid model components
are computed depending on the criterion that is used to solve the ambiguities AmbiguityCriterion, the
maximum allowable contour overlap MaxContourOverlap, and the cluster threshold ClusterThreshold
(see train_model_components). The cluster threshold, for example, influences the merging of the initial
components. The greater the threshold is chosen, the fewer initial components are merged. The determined rigid
model components are returned in ModelComponents.

Hence, after the components have been trained once by using train_model_components,
inspect_clustered_components can be used to estimate the effect of different values for the parameters
AmbiguityCriterion, MaxContourOverlap, and ClusterThreshold without performing the complete training procedure several times. Once the desired parameter values have been found, they can be
efficiently adopted into the training result by using cluster_model_components.

Parameters

▷ ModelComponents (output_object) ......................... region(-array) ~ object
Contour regions of rigid model components.
▷ ComponentTrainingID (input_control) ................... component_training ~ handle
Handle of the training result.
▷ AmbiguityCriterion (input_control) ...................... string ~ string
Criterion for solving the ambiguities.
Default value: 'rigidity'
List of values: AmbiguityCriterion ∈ { 'distance', 'orientation', 'distance_orientation', 'rigidity' }

HALCON 20.11.0.0
MaxContourOverlap (input_control) ................................................. real \( \mapsto \) real

Maximum contour overlap of the found initial components.

Default value: 0.2

Suggested values: \( \text{MaxContourOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)

Minimum increment: 0.01

Recommended increment: 0.05

Restriction: \( 0 \leq \text{MaxContourOverlap} \&\& \text{MaxContourOverlap} \leq 1 \)

ClusterThreshold (input_control) ................................................. real \( \mapsto \) real

Threshold for clustering the initial components.

Default value: 0.5

Suggested values: \( \text{ClusterThreshold} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)

Restriction: \( 0 \leq \text{ClusterThreshold} \&\& \text{ClusterThreshold} \leq 1 \)

--- Example ---

* Get the model image.

```
read_image (ModelImage, 'model_image.tif')
```

* Define the regions for the initial components.

```
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
```

* Get the training images

```
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
  read_image (TrainingImage, 'training_image-'+i$'02'+'.tif')
  concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
```

* Extract the model components and train the relations.

```
train_model_components (ModelImage, InitialComponentRegions, 
  TrainingImages, ModelComponents, 22, 60, 30, 0.65, 
  
  ComponentTrainingID)
```

* Find the best value for the parameter ClusterThreshold.

```
inspect_clustered_components (ModelComponents, ComponentTrainingID, 
  'rigidity', 0.2, 0.4)
```

* Adopt the ClusterThreshold into the training result.

```
cluster_model_components (ModelComponents, ModelComponents, 
  ComponentTrainingID, 'rigidity', 0.2, 0.4)
```

* Create the component model based on the training result.

```
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, 
  0.5, 'auto', 'auto', 'none', 
  'use_polarity', 'false', ComponentModelID, 
  RootRanking)
```

--- Result ---

If the handle of the training result is valid, the operator `inspect_clustered_components` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

--- Execution Information ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
Modify the relations within a training result.

modify_component_relations modifies the relations between the model components within the component training result ComponentTrainingID. The selection of the relation(s) that should be changed is performed by setting ReferenceComponent and ToleranceComponent, respectively. This means that the relative movement of component ToleranceComponent with respect to the component ReferenceComponent is modified.

The size of the change is specified as follows: By specifying a position tolerance PositionTolerance, the semi-axes of the rectangle that describes the reference point’s movement (see train_model_components) are enlarged by PositionTolerance pixels. Accordingly, by specifying an orientation tolerance AngleTolerance, the angle range that describes the variation of the relative orientation (see train_model_components) is enlarged by AngleTolerance to both sides. Consequently, negative tolerance values lead to a decreased size of the relations. The operator modify_component_relations is particularly useful when the training images that were used during the training do not cover the entire spectrum of the relative movements.

In order to select the relations that should be modified, values for ReferenceComponent and ToleranceComponent can be passed in one of the following ways: For each of both parameters either one value, several values, or the string ‘all’ can be passed. The following table summarizes the different possibilities by giving the affected relations for different combinations of parameter values. Here, four model components are assumed (0, 1, 2, and 3). If, for example, ReferenceComponent is set to 0 and ToleranceComponent is set to 1, then the relation (0,1), which corresponds to the relative movement of component 1 with respect to component 0, will be modified.
The number of tolerance values passed in PositionTolerance and AngleTolerance must be either 1 or be equal to the number of affected relations. In the former case all affected relations are modified by the same value, whereas in the latter case each relation can be modified individually by passing different values within a tuple.

The parameters of the operation include:

- **ComponentTrainingID** (input_control) 
  - Type: component_training
  - Description: Handle of the training result.

- **ReferenceComponent** (input_control) 
  - Type: string(-array) ~/ string / integer
  - Description: Model component(s) relative to which the movement(s) should be modified.
  - Default value: 'all'
  - Suggested values: ReferenceComponent ∈ {'all', 0, 1, 2, 3, 4, 5, 6}

- **ToleranceComponent** (input_control) 
  - Type: string(-array) ~/ string / integer
  - Description: Model component(s) of which the relative movement(s) should be modified.
  - Default value: 'all'
  - Suggested values: ToleranceComponent ∈ {'all', 0, 1, 2, 3, 4, 5, 6}

- **PositionTolerance** (input_control) 
  - Type: real(-array) ~/ real
  - Description: Change of the position relation in pixels.
  - Suggested values: PositionTolerance ∈ {1.0, 2.0, 3.0, 4.0, 5.0, 10.0, 20.0, 30.0}

- **AngleTolerance** (input_control) 
  - Type: angle.rad(-array) ~/ real
  - Description: Change of the orientation relation in radians.
  - Suggested values: AngleTolerance ∈ [0.017, 0.035, 0.052, 0.070, 0.087, 0.175, 0.349]

The result of the operation is:

- If the handle of the training result is valid, the operator `modify_component_relations` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
This operator modifies the state of the following input parameter:

- ComponentTrainingID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

HALCON/HDevelop Reference Manual, 2020-11-10
serialize_training_components (  
    : : ComponentTrainingID : SerializedItemHandle )

Serialize a component training result.

serialize_training_components serializes the data of a component training result (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_training_components is converted to a serialized item. The component training result is defined by the handle ComponentTrainingID. The serialized component training result is returned by the handle SerializedItemHandle and can be deserialized by deserialize_training_components.

Parameters

▷ ComponentTrainingID (input_control) ........................component_training ~ handle  
Handle of the training result.
▷ SerializedItemHandle (output_control) ......................serialized_item ~ handle  
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_training_components returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

    TrainingEmphasis, AmbiguityCriterion, MaxContourOverlap,  
    ClusterThreshold : ComponentTrainingID )

Train components and relations for the component-based matching.

train_model_components extracts the final (rigid) model components and trains their mutual relations, i.e., their relative movements, on the basis of the initial components by considering several training images. The result of the training is returned in the handle ComponentTrainingID. The training result can be subsequently used to create the actual component model using create_trained_component_model.

train_model_components should be used in cases where the relations of the components are not known and should be trained automatically. In contrast, if the relations are known no training needs to be performed with train_model_components. Instead, the component model can be directly created with create_component_model.

If the initial components have been automatically created by using gen_initial_components, InitialComponents contains the contour regions of the initial components. In contrast, if the initial components should be defined by the user, they can be directly passed in InitialComponents. However, instead of the contour regions for each initial component, its enclosing region must be passed in the tuple. The (contour) regions refer to the model image ModelImage. If the initial components have been obtained using gen_initial_components, the model image should be the same as in gen_initial_components. Please note that each initial component is part of at most one rigid model component. This is because during the
training initial components can be merged into rigid model components if required (see below). However, they cannot be split and distributed to several rigid model components.

\texttt{train\_model\_components} uses the following approach to perform the training: In the first step, the initial components are searched in all training images. In some cases, one initial component may be found in an training image more than once. Thus, in the second step, the resulting ambiguities are solved, i.e., the most probable pose of each initial component is found. Consequently, after solving the ambiguities, in all training images at most one pose of each initial component is available. In the next step the poses are analyzed and those initial components that do not show any relative movement are clustered to the final rigid model components. Finally, in the last step the relations between the model components are computed by analyzing their relative poses over the sequence of training images. The parameters that are associated with the mentioned steps are explained in the following.

The training is performed based on several training images, which are passed in 
\texttt{TrainingImages}. Each training image must show at most one instance of the compound object and should contain the full range of allowed relative movements of the model components. If, for example, the component model of an on/off switch should be trained, one training image that shows the switch turned off is sufficient if the switch in the model image is turned on, or vice versa.

The principle of the training is to find the initial components in all training images and to analyze their poses. For this, for each initial component a shape model is created (see \texttt{create\_shape\_model}), which is then used to determine the poses (position and orientation) of the initial components in the training images (see \texttt{find\_shape\_model}). Depending on the mode that is set by using \texttt{set\_system}\texttt{('pregenerate\_shape\_models',...)}, the shape model is either pregenerated completely or computed online during the search. The mode influences the computation time as well as the robustness of the training. Furthermore, it should be noted that if single-channel image are used in \texttt{ModelImage} as well as in \texttt{TrainingImages} the metric \texttt{'use\_polarity'} is used internally for \texttt{create\_shape\_model}, while if multichannel images are used in either \texttt{ModelImage} or \texttt{TrainingImages} the metric \texttt{'ignore\_color\_polarity'} is used. Finally, it should be noted that while the number of channels in \texttt{ModelImage} and \texttt{TrainingImages} may be different, e.g., to facilitate model generation from synthetically generated images, the number of channels in all the images in \texttt{TrainingImages} must be identical. For further details see 
\texttt{create\_shape\_model}. The creation of the shape models can be influenced by choosing appropriate values for the parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize}. These parameters have the same meaning as in \texttt{gen\_initial\_components} and can be automatically determined by passing \texttt{'auto'}: If both hysteresis threshold should be automatically determined, both \texttt{ContrastLow} and \texttt{ContrastHigh} must be set to \texttt{'auto'}. In contrast, if only one threshold value should be determined, \texttt{ContrastLow} must be set to \texttt{'auto'} while \texttt{ContrastHigh} must be set to an arbitrary value different from \texttt{'auto'}. If the initial components have been automatically created by \texttt{gen\_initial\_components}, the parameters \texttt{ContrastLow}, \texttt{ContrastHigh}, and \texttt{MinSize} should be set to the same values as in \texttt{gen\_initial\_components}.

To influence the search for the initial components, the parameters \texttt{MinScore}, \texttt{SearchRowTol}, \texttt{SearchColumnTol}, \texttt{SearchAngleTol}, and \texttt{TrainingEmphasis} can be set. The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the initial component in the training image. The larger \texttt{MinScore} is chosen, the faster the training is. If the initial components can be expected never to be occluded in the training images, \texttt{MinScore} may be set as high as 0.8 or even 0.9 (see \texttt{find\_shape\_model}).

By default, the components are searched only at points in which the component lies completely within the respective training image. This means that a component will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than \texttt{MinScore}. This behavior can be changed with \texttt{set\_system}\texttt{('border\_shape\_models','true')}, which will cause components that extend beyond the image border to be found if they achieve a score greater than \texttt{MinScore}. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the training will increase in this mode.

When dealing with a high number of initial components and many training images, the training may take a long time (up to several minutes). In order to speed up the training it is possible to restrict the search space for the single initial components in the training images. For this, the poses of the initial components in the model image are used as reference pose. The parameters \texttt{SearchRowTol} and \texttt{SearchColumnTol} specify the position tolerance region relative to the reference position in which the search is performed. Assume, for example, that the position of an initial component in the model image is (100,200) and \texttt{SearchRowTol} is set to 20 and \texttt{SearchColumnTol} is set to 10. Then, this initial component is searched in the training images only within the axis-aligned rectangle that is determined by the upper left corner (80,190) and the lower right corner (120,210). The same holds for the orientation angle range, which can be restricted by specifying the angle tolerance \texttt{SearchAngleTol} to
the angle range of \([-\text{SearchAngleTol},+\text{SearchAngleTol}]\). Thus, it is possible to considerably reduce the computational effort during the training by an adequate acquisition of the training images. If one of the three parameters is set to -1, no restriction of the search space is applied in the corresponding dimension.

The input parameters \(\text{ContrastLow}, \text{ContrastHigh}, \text{MinSize}, \text{MinScore}, \text{SearchRowTol}, \text{SearchColumnTol}, \text{SearchAngleTol}\) must either contain one element, in which case the parameter is used for all initial components, or must contain the same number of elements as the initial components contained in \(\text{InitialComponents}\), in which case each parameter element refers to the corresponding initial component in \(\text{InitialComponents}\).

The parameter \(\text{TrainingEmphasis}\) offers another possibility to influence the computation time of the training and to simultaneously affect its robustness. If \(\text{TrainingEmphasis}\) is set to ‘speed’, on the one hand the training is comparatively fast, on the other hand it may happen in some cases that some initial components are not found in the training images or are found at a wrong pose. Consequently, this would lead to an incorrect computation of the rigid model components and their relations. The poses of the found initial components in the individual training images can be examined by using \(\text{get\_training\_components}\). If erroneous matches occur the training should be restarted with \(\text{TrainingEmphasis}\) set to ‘reliability’. This results in a higher robustness at the cost of a longer computation time.

Furthermore, during the pose determination of the initial components ambiguities may occur if the initial components are rotationally symmetric or if several initial components are identical or at least similar to each other. To solve the ambiguities, the most probable pose is calculated for each initial component in each training image. For this, the individual ambiguous poses are evaluated. The pose of an initial component receives a good evaluation if the relative pose of the initial component with respect to the other initial components is similar to the corresponding relative pose in the model image. The method to evaluate this similarity can be chosen with \(\text{AmbiguityCriterion}\). In almost all cases the best results are obtained with ‘rigidity’, which assumes the rigidity of the compound object. The more the rigidity of the compound object is violated by the pose of the initial component, the worse its evaluation is. In the case of ‘distance’, only the distance between the initial components is considered during the evaluation. Hence, the pose of the initial component receives a good evaluation if its distances to the other initial components is similar to the corresponding distances in the model image. Accordingly, when choosing ‘orientation’, only the relative orientation is considered during the evaluation. Finally, the simultaneous consideration of distance and orientation can be achieved by choosing ‘distance\_orientation’. In contrast to ‘rigidity’, the relative pose of the initial components is not considered when using ‘distance\_orientation’.

The process of solving the ambiguities can be further influenced by the parameter \(\text{MaxContourOverlap}\). This parameter describes the extent by which the contours of two initial component matches may overlap each other. Let the letters ‘I’ and ‘T’, for example, be two initial components that should be searched in a training image that shows the string ‘IT’. Then, the initial component ‘I’ should be found at its correct pose. In contrast, the initial component ‘T’ will be found at its correct pose (‘I’) but also at the pose of the ‘T’ because of the similarity of the two components. To discard the wrong match of the initial component ‘I’, an appropriate value for \(\text{MaxContourOverlap}\) can be chosen: If overlapping matches should be tolerated, \(\text{MaxContourOverlap}\) should be set to 1. If overlapping matches should be completely avoided, \(\text{MaxContourOverlap}\) should be set to 0. By choosing a value between 0 and 1, the maximum percentage of overlapping contour pixels can be adjusted.

The decision which initial components can be clustered to rigid model components is made based on the poses of the initial components in the model image and in the training images. Two initial components are merged if they do not show any relative movement over all images. Assume that in the case of the above mentioned switch the training image would show the same switch state as the model image, the algorithm would merge the respective initial components because it assumes that the entire switch is one rigid model component. The extent by which initial components are merged can be influenced with the parameter \(\text{ClusterThreshold}\). This cluster threshold is based on the probability that two initial components belong to the same rigid model component. Thus, \(\text{ClusterThreshold}\) describes the minimum probability which two initial components must have in order to be merged. Since the threshold is based on a probability value, it must lie in the interval between 0 and 1. The greater the threshold is chosen, the smaller the number of initial components that are merged. If a threshold of 0 is chosen, all initial components are merged into one rigid component, while for a threshold of 1 no merging is performed and each initial component is adopted as one rigid model component.

The final rigid model components are returned in \(\text{ModelComponents}\). Later, the index of a component region in \(\text{ModelComponents}\) is used to denote the model component. The poses of the components in the training images can be examined by using \(\text{get\_training\_components}\).

After the determination of the model components their relative movements are analyzed by determining the movement of one component with respect to a second component for each pair of components. For this, the components are referred to their reference points. The reference point of a component is the center of gravity of its contour
region, which is returned in ModelComponents. It can be calculated by calling area_center. Finally, the relative movement is represented by the smallest enclosing rectangle of arbitrary orientation of the reference point movement and by the smallest enclosing angle interval of the relative orientation of the second component over all images. The determined relations can be inspected by using get_component_relations.

---

**Parameters**

- **ModelImage** (input_object) \(\sim\) object : byte / uint2
  Input image from which the shape models of the initial components should be created.

- **InitialComponents** (input_object) \(\sim\) region-array \(\sim\) object
  Contour regions or enclosing regions of the initial components.

- **TrainingImages** (input_object) \(\sim\) (multichannel-)imaget-array \(\sim\) object : byte / uint2
  Training images that are used for training the model components.

- **ModelComponents** (output_object) \(\sim\) region(-array) \(\sim\) object
  Contour regions of rigid model components.

- **ContrastLow** (input_control) \(\sim\) integer(-array) \(\sim\) integer / string
  Lower hysteresis threshold for the contrast of the initial components in the image.
  Default value: ‘auto’
  Suggested values: \(\text{ContrastLow} \in \{\text{’auto’}, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\}\)
  Restriction: \(\text{ContrastLow} > 0\)

- **ContrastHigh** (input_control) \(\sim\) integer(-array) \(\sim\) integer / string
  Upper hysteresis threshold for the contrast of the initial components in the image.
  Default value: ‘auto’
  Suggested values: \(\text{ContrastHigh} \in \{\text{’auto’}, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\}\)
  Restriction: \(\text{ContrastHigh} > 0 \&\& \text{ContrastHigh} \geq \text{ContrastLow}\)

- **MinSize** (input_control) \(\sim\) integer(-array) \(\sim\) integer / string
  Minimum size of connected contour regions.
  Default value: ‘auto’
  Suggested values: \(\text{MinSize} \in \{\text{’auto’}, 0, 5, 10, 20, 30, 40\}\)
  Restriction: \(\text{MinSize} \geq 0\)

- **MinScore** (input_control) \(\sim\) real(-array) \(\sim\) real
  Minimum score of the instances of the initial components to be found.
  Default value: 0.5
  Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Minimum increment: 0.01
  Recommended increment: 0.05
  Restriction: \(0 \leq \text{MinScore} \&\& \text{MinScore} \leq 1\)

- **SearchRowTol** (input_control) \(\sim\) integer(-array) \(\sim\) integer
  Search tolerance in row direction.
  Default value: -1
  Suggested values: \(\text{SearchRowTol} \in \{0, 10, 20, 30, 50, 100\}\)
  Restriction: \(\text{SearchRowTol} = -1 \&\& \text{SearchRowTol} \geq 0\)

- **SearchColumnTol** (input_control) \(\sim\) integer(-array) \(\sim\) integer
  Search tolerance in column direction.
  Default value: -1
  Suggested values: \(\text{SearchColumnTol} \in \{0, 10, 20, 30, 50, 100\}\)
  Restriction: \(\text{SearchColumnTol} = -1 \&\& \text{SearchColumnTol} \geq 0\)

- **SearchAngleTol** (input_control) \(\sim\) angle.rad(-array) \(\sim\) real
  Angle search tolerance.
  Default value: -1
  Suggested values: \(\text{SearchAngleTol} \in \{0.0, 0.17, 0.39, 0.78, 1.57\}\)
  Restriction: \(\text{SearchAngleTol} = -1 \&\& \text{SearchAngleTol} \geq 0\)

- **TrainingEmphasis** (input_control) \(\sim\) string
  Decision whether the training emphasis should lie on a fast computation or on a high robustness.
  Default value: ‘speed’
  List of values: TrainingEmphasis \(\in \{\text{’speed’, ’reliability’}\}\)
18.1. COMPONENT-BASED

- **AmbiguityCriterion** (input_control)  
  Criterion for solving ambiguous matches of the initial components in the training images.
  
  **Default value:** "rigidity"
  
  **List of values:** AmbiguityCriterion ∈ {'distance', 'orientation', 'distance_orientation', 'rigidity'}

- **MaxContourOverlap** (input_control)  
  Maximum contour overlap of the found initial components in a training image.
  
  **Default value:** 0.2
  
  **Suggested values:** MaxContourOverlap ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  
  **Minimum increment:** 0.01
  
  **Recommended increment:** 0.05
  
  **Restriction:** 0 <= MaxContourOverlap && MaxContourOverlap <= 1

- **ClusterThreshold** (input_control)  
  Threshold for clustering the initial components.
  
  **Default value:** 0.5
  
  **Suggested values:** ClusterThreshold ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  
  **Restriction:** 0 <= ClusterThreshold && ClusterThreshold <= 1

- **ComponentTrainingID** (output_control)  
  Handle of the training result.

---

**Example**

* Get the model image.
  read_image (ModelImage, 'model_image.tif')
  
* Define the regions for the initial components.
  gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
  gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
  gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
  gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
  concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
  concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
  
* Get the training images.
  gen_empty_obj (TrainingImages)
  for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-' + i + '.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
  endfor
* Extract the model components and train the relations.
  train_model_components (ModelImage, InitialComponentRegions, \TrainingImages, ModelComponents, 22, 60, 30, 0.6, \0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \ComponentTrainingID)

---

**Result**

If the parameter values are correct, the operator train_model_components returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**write_component_model** ( : : ComponentModelID, FileName : )

Write a component model to a file.

The operator **write_component_model** writes the component model `ComponentModelID` to the file `FileName`. The model can be read again with **read_component_model**. The default HALCON file extension for the component model is `cbm`.

**Parameters**

- **ComponentModelID** (input_control) ... handle component_model
  Handle of the component model.
- **FileName** (input_control) ... filename.write
  File name.
  **File extension:** .cbm

**Result**

If the file name is valid (write permission), the operator **write_component_model** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

#### `clear_ncc_model` ( : : ModelID : )

Free the memory of an NCC model.

The operator `clear_ncc_model` frees the memory of an NCC model that was created by `create_ncc_model`. After calling `clear_ncc_model`, the model can no longer be used. The handle `ModelID` becomes invalid.

**Parameters**

- `ModelID` (input_control) .............................................................. ncc_model ↦ handle
  
  Handle of the model.

**Result**

If the handle of the model is valid, the operator `clear_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`  

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Module**

Matching

#### `create_ncc_model` ( Template : : NumLevels, AngleStart, AngleExtent, AngleStep, Metric : ModelID )

Prepare an NCC model for matching.
The operator create_ncc_model prepares a template, which is passed in the image Template, as an NCC model used for matching using the normalized cross correlation (NCC). The ROI of the model is passed as the domain of Template.

The model is generated using multiple image pyramid levels at multiple rotations on each level and is stored in memory. The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_ncc_model.

The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least eight) on the highest pyramid level. This can be checked using the domains of the output images of gen_gauss_pyramid. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_ncc_model returns an error message. If NumLevels is set to 'auto' or 0, create_ncc_model determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using get_ncc_model_params. In rare cases, it might happen that create_ncc_model determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore in find_ncc_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_ncc_model may increase. In these cases, the number of pyramid levels should be selected by inspecting the output of gen_gauss_pyramid. Here, Mode = 'constant' and Scale = 0.5 should be used.

The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by find_ncc_model. The parameter AngleStep determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in find_ncc_model, this parameter specifies the accuracy that is achievable for the angles in find_ncc_model. AngleStep should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence AngleStep should be chosen larger for smaller models. If AngleExtent is not an integer multiple of AngleStep, AngleStep is modified accordingly. To ensure a sampling of the range of possible rotations that is independent of the given AngleStart, the range of possible rotations is modified as follows: If there is no positive integer value n such that AngleStart plus n times AngleStep is exactly 0.0, AngleStart is decreased by up to AngleStep and AngleExtent is increased by AngleStep.

The model is pre-generated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if AngleStep is too small or AngleExtent too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep must be enlarged or AngleExtent must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_ncc_model, AngleStep ≥ 1 can be selected for models of a diameter smaller than about 200 pixels. If AngleStep = 'auto' or 0 is selected, create_ncc_model automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using get_ncc_model_params.

The parameter Metric determines the conditions under which the model is recognized in the image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_ncc_model will increase slightly in this case.

The center of gravity of the domain (region) of the model image Template is used as the origin (reference point) of the model. A different origin can be set with set_ncc_model_origin.

**Parameters**

* Template (input_object) .................. singlechannelimage ~ object: byte / uint2
  Input image whose domain will be used to create the model.
18.2. CORRELATION-BASED

- **NumLevels** (input_control) ........................................... integer $\sim$ integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: NumLevels $\in$ ['auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

- **AngleStart** (input_control) ........................................... angle.rad $\sim$ real
  Smallest rotation of the pattern.
  Default value: -0.39
  Suggested values: AngleStart $\in$ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]

- **AngleExtent** (input_control) ........................................... angle.rad $\sim$ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent $\in$ [6.29, 3.14, 1.57, 0.79, 0.39]
  Restriction: AngleExtent $\geq$ 0

- **AngleStep** (input_control) ........................................... angle.rad $\sim$ real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: AngleStep $\in$ ['auto', 0.0, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]
  Restriction: AngleStep $\geq$ 0 && AngleStep $\leq$ pi / 16

- **Metric** (input_control) ........................................... string $\sim$ string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric $\in$ ['use_polarity', 'ignore_global_polarity']

- **ModelID** (output_control) ........................................... ncc_model $\sim$ handle
  Handle of the model.

---

If the parameters are valid, the operator `create_ncc_model` returns the value 2 (H_MSG_TRUE). If the parameter **NumLevels** are chosen such that the model contains too few points, the error 8506 is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```plaintext
deserialize_ncc_model ( : : SerializedItemHandle : ModelID )
```

**Deserializes an NCC model.**

`deserialize_ncc_model` deserializes an NCC model, that was serialized by `serialize_ncc_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized NCC model model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created NCC model with the handle `ModelID`.
Parameters

- **SerializedItemHandle** (input_control) .................................................... serialized_item ⇔ handle
  Handle of the serialized item.
- **ModelID** (output_control) ................................................................. ncc_model ⇔ handle
  Handle of the model.

Result

If the parameters are valid, the operator `deserialize_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

Module

Matching

determine_ncc_model_params ( Template : : NumLevels, AngleStart, AngleExtent, Metric, Parameters : ParameterName, ParameterValue )

Determine the parameters of an NCC model.

determine_ncc_model_params determines certain parameters of an NCC model automatically from the model image `Template`. The parameters to be determined can be specified with `Parameters`. `determine_ncc_model_params` can be used to determine the same parameters that are determined automatically when the respective parameter in `create_ncc_model` is set to 'auto': the number of pyramid levels (`Parameters = 'num_levels'`) and/or the angle step length (`Parameters = 'angle_step'`). By passing a tuple of the above values in `Parameters`, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed.

determine_ncc_model_params is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in `ParameterName` and `ParameterValue`. The parameter names in `ParameterName` are identical to the names in `Parameters`, where, of course, the value 'all' is replaced by the actual parameter names.

The input parameters (`NumLevels, AngleStart, AngleExtent, and Metric`) have the same meaning as in `create_ncc_model`. The description of these parameters can be looked up with this operator. These parameters are used by `determine_ncc_model_params` to calculate the parameters to be determined in the same manner as in `create_ncc_model`.

Note that in `determine_ncc_model_params` the input parameter `NumLevels` can also be determined automatically. If this parameter should not be determined automatically, i.e., the name is not passed in `Parameters`, the parameter must contain a valid value and must not be set to 'auto'. In contrast, if the maximum number of pyramid levels is to be determined automatically, i.e., `Parameters` contains the value 'num_levels', you can let HALCON determine a suitable value and at the same time specify an upper boundary:

If the maximum number of pyramid levels should be specified in advance, the input parameter `NumLevels` can be set to the particular value. If in this case `Parameters` contains the value 'num_levels', the computed number of pyramid levels is at most `NumLevels`. If `NumLevels` is set to 'auto' or 0, the number of pyramid levels is determined without restrictions as large as possible.
18.2. CORRELATION-BASED

Parameters

▶ **Template** (input_object) .................................................. singlechannelimage \(\sim\) object : byte / uint2
  Input image whose domain will be used to create the model.

▶ **NumLevels** (input_control) ......................................... integer \(\sim\) integer / string
  Maximum number of pyramid levels.
  Default value: ‘auto’
  List of values: NumLevels \(\in\) \{'auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

▶ **AngleStart** (input_control) ........................................... angle.rad \(\sim\) real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: AngleStart \(\in\) \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}
  Restriction: AngleExtent \(\geq\) 0

▶ **AngleExtent** (input_control) ......................................... angle.rad \(\sim\) real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent \(\in\) \{6.29, 3.14, 1.57, 0.79, 0.39\}
  Restriction: AngleExtent \(\geq\) 0

▶ **Metric** (input_control) ................................................ string \(\sim\) string
  Match metric.
  Default value: ‘use_polarity’
  List of values: Metric \(\in\) \{'use_polarity’, ‘ignore_global_polarity’\}

▶ **Parameters** (input_control) ........................................... string(-array) \(\sim\) string
  Parameters to be determined automatically.
  Default value: ‘all’
  List of values: Parameters \(\in\) \{'all’, ‘num_levels’, ‘angle_step’\}

▶ **ParameterName** (output_control) ................................. string-array \(\sim\) string
  Name of the automatically determined parameter.

▶ **ParameterValue** (output_control) ................................. number-array \(\sim\) real / integer
  Value of the automatically determined parameter.

Result

If the parameters are valid, the operator determine_ncc_model_params returns the value 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Successors

create_ncc_model

See also

find_ncc_model

Module

Matching

```
find_ncc_model ( Image : : ModelID, AngleStart, AngleExtent,
                  MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels : Row,
                  Column, Angle, Score )
```

Find the best matches of an NCC model in an image.

The operator find_ncc_model finds the best NumMatches instances of the NCC model ModelID in
the input image Image. The model must have been created previously by calling create_ncc_model or
read_ncc_model.

The position and rotation of the found instances of the model is returned in Row, Column, and Angle. Additionally, the score of each found instance is returned in Score.
It should be noted that the NCC is very sensitive to occlusion and clutter as well as to nonlinear illumination changes in the image. If a model should be found in the presence of occlusion, clutter, or nonlinear illumination changes the search should be performed using the shape-based matching (see, e.g., create_shape_model).

**Input parameters in detail**

**The image and its domain:** The domain of the image *Image* determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the NCC model with create_ncc_model. A different origin set with set_ncc_model_origin is not taken into account here. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that rounding effects can cause matches to lie up to \(0.5 + 2^{\text{NumLevels}}\) pixels outside the image.

**AngleStart and AngleExtent:** The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with create_ncc_model.

**MinScore:** The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is.

**NumMatches:** The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

**MaxOverlap:** If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. If the model has repeating structures it may happen that multiple instances with identical rotations are found at similar positions in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

**SubPixel:** The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to ‘false’, the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with create_ncc_model. If SubPixel is set to ‘true’, the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves a high accuracy. Hence, SubPixel should usually be set to ‘true’. Note that the subpixel accurate determination of the model’s pose is only possible if the found instance lies at least 2 pixels away from the image border of the lowest used pyramid level. If the instance lies closer to the image border, its pose is only determined with pixel accuracy and the angle resolution that was specified with create_ncc_model, even if SubPixel is set to ‘true’.

**NumLevels:** The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the NCC model was created with create_ncc_model. If NumLevels is set to 0, the number of pyramid levels specified in create_ncc_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_ncc_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_ncc_model_params and then use a slightly lower value in find_ncc_model. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances
of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

Output parameters in detail

Row, Column and Angle: The position and rotation of the found instances of the model is returned in Row, Column, and Angle. The coordinates Row and Column are related to the position of the origin of the model in the search image. However, Row and Column do not exactly correspond to this position. Instead, find_ncc_model returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model. (This has to do with the way HALCON transforms iconic objects, see affine_trans_pixel). The example below shows how to create the transformation matrix for alignment and how to calculate the exact coordinates of the found matches.

By default, the origin is the center of gravity of the domain (region) of the image that was used to create the NCC model with create_ncc_model. A different origin can be set with set_ncc_model_origin.

Score: Additionally, the score of each found instance is returned in Score. The score is the normalized cross correlation of the template \( t(r, c) \) and the image \( i(r, c) \):

\[
ncc(r, c) = \frac{1}{n} \sum_{(u,v) \in R} \frac{t(u, v) - m_t}{\sqrt{s_t^2}} \cdot \frac{i(r + u, c + v) - m_i(r, c)}{\sqrt{s_i^2(r, c)}}
\]

Here, \( n \) denotes the number of points in the template, \( R \) denotes the domain (ROI) of the template, \( m_t \) is the mean gray value of the template

\[
m_t = \frac{1}{n} \sum_{(u,v) \in R} t(u, v)
\]

\( s_t^2 \) is the variance of the gray values of the template

\[
s_t^2 = \frac{1}{n} \sum_{(u,v) \in R} (t(u, v) - m_t)^2
\]

\( m_i(r, c) \) is the mean gray value of the image at position \( (r, c) \) over all points of the template (i.e., the template points are shifted by \( (r, c) \))

\[
m_i(r, c) = \frac{1}{n} \sum_{(u,v) \in R} i(r + u, c + v)
\]

and \( s_i^2(r, c) \) is the variance of the gray values of the image at position \( (r, c) \) over all points of the template

\[
s_i^2(r, c) = \frac{1}{n} \sum_{(u,v) \in R} (i(r + u, c + v) - m_i(r, c))^2
\]

The NCC measures how well the template and image correspond at a particular point \( (r, c) \). It assumes values between \(-1\) and \(1\). The larger the absolute value of the correlation, the larger the degree of correspondence between the template and image. A value of \(1\) means that the gray values in the image are a linear transformation of the gray values in the template:

\[
i(r + u, c + v) = at(u, v) + b
\]

where \( a > 0 \). Similarly, a value of \(-1\) means that the gray values in the image are a linear transformation of the gray values in the template with \( a < 0 \). Hence, in this case the template occurs with a reversed polarity in the image. Because of the above property, the NCC is invariant to linear illumination changes.

The NCC as defined above is used if the NCC model has been created with Metric = 'use_polarity'. If the model has been created with Metric = 'ignore_global_polarity', the absolute value of \( ncc(r, c) \) is used as the score.
CHAPTER 18 MATCHING

Specifying a timeout

Using the operator `set_ncc_model_param` you can specify a 'timeout' for `find_ncc_model`. If `find_ncc_model` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by correlation-based matching, we highly recommend the usage of the procedure `dev_display_ncc_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

`find_ncc_model` can be partially executed on OpenCL devices that support the cl_khr_global_int32_base_atomics OpenCL extension. Only the initial search for the model in the topmost pyramid level is done on the OpenCL device, while the tracking of matches is done on the host CPU. If the domain of the image to search in is substantially smaller than the size of the image, use `crop_domain` to reduce the amount of data that needs to be copied from the OpenCL device to the host CPU. Note that `find_ncc_model` using OpenCL may run either substantially faster or slower depending on a wide number of factors, so the only way to tell if using OpenCL is beneficial is by testing with images from the actual application.

Furthermore, note that the internally used memory increases with the number of used threads.

Parameters

- **Image** (input_object): singlechannelimage ~ object: byte / uint2
  Input image in which the model should be found.
- **ModelID** (input_control): ncc_model ~ handle
  Handle of the model.
- **AngleStart** (input_control): angle.rad ~ real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: `AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]`
- **AngleExtent** (input_control): angle.rad ~ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: `AngleExtent ∈ [6.29, 3.14, 1.57, 0.79, 0.39, 0.0]`
  Restriction: `AngleExtent ≥ 0`
- **MinScore** (input_control): real ~ real
  Minimum score of the instances of the model to be found.
  Default value: 0.8
  Suggested values: `MinScore ∈ [0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  Typical range of values: `0 ≤ MinScore ≤ 1`
  Minimum increment: 0.01
  Recommended increment: 0.05
- **NumMatches** (input_control): integer ~ integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: `NumMatches ∈ [0, 1, 2, 3, 4, 5, 10, 20]`
- **MaxOverlap** (input_control): real ~ real
  Maximum overlap of the instances of the model to be found.
  Default value: 0.5
  Suggested values: `MaxOverlap ∈ [0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  Typical range of values: `0 ≤ MaxOverlap ≤ 1`
  Minimum increment: 0.01
  Recommended increment: 0.05
- **SubPixel** (input_control): string ~ string
  Subpixel accuracy.
  Default value: 'true'
  List of values: `SubPixel ∈ ['false', 'true']`
18.2. CORRELATION-BASED

- **NumLevels** (input_control) ................................................. integer(-array) \text{⇒} integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).
  
  **Default value:** 0
  
  **List of values:** NumLevels ∈ \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

- **Row** (output_control) ......................................................... point.y-array \text{⇒} real
  Row coordinate of the found instances of the model.

- **Column** (output_control) ................................................... point.x-array \text{⇒} real
  Column coordinate of the found instances of the model.

- **Angle** (output_control) ..................................................... angle.rad-array \text{⇒} real
  Rotation angle of the found instances of the model.

- **Score** (output_control) ..................................................... real-array \text{⇒} real
  Score of the found instances of the model.

---

**Example**

```plaintext
create_ncc_model (TemplateImage, 'auto', rad(-45), rad(90), 'auto', 
                   'use_polarity', ModelID)
find_ncc_model (SearchImage, ModelID, rad(-45), rad(90), 0.7, 1, 
                0.5, 'true', 0, Row, Column, Angle, Score)

* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2D)
* Calculate true position of the model origin in the search image
affine_trans_pixel (HomMat2D, 0, 0, RowObject, ColumnObject)
* display the results
dev_display_ncc_matching_results (ModelID, 'red', Row, Column, 
                                 Angle, 0)
```

---

**Result**

If the parameter values are correct, the operator `find_ncc_model` returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via `set_system` ('no_object_result',<Result>). If necessary, an exception is raised.

---

**Execution Information**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

---

**Possible Predecessors**

- `create_ncc_model`
- `read_ncc_model`
- `set_ncc_model_origin`

---

**Possible Successors**

- `clear_ncc_model`

---

**Alternatives**

- `find_shape_model`
- `find_scaled_shape_model`
- `find_aniso_shape_model`
- `find_shape_models`
- `find_scaled_shape_models`
- `find_aniso_shape_models`

---

**Module**

Matching

```plaintext
find_ncc_models ( Image : , ModelIDs, AngleStart, AngleExtent, 
                  MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels : Row, 
                  Column, Angle, Score, Model )
```

Find the best matches of multiple NCC models.

The operator `find_ncc_models` finds the best `NumMatches` instances of the NCC models that are passed in the tuple `ModelIDs` in the input `Image`. The models must have been created previously by calling...
create_ncc_model or read_ncc_model. In contrast to find_ncc_model, multiple models can be searched in the same image in one call.

Characteristics of the parameter semantics

Compared to find_ncc_model, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or they must contain the same number of elements as ModelIDs, in which case each parameter element refers to the corresponding element in ModelIDs. (NumLevels may also contain either two or twice the number of elements as ModelIDs). More details can be found below in the sections containing information for the respective parameters. Note that a call to find_ncc_models with multiple values for ModelIDs, NumMatches and MaxOverlap has the same effect as multiple independent calls to find_ncc_model with the respective parameters. However, a single call to find_ncc_models is considerably more efficient.

Input parameters in detail

The image and its domain: The domain of the image Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the NCC model with create_ncc_model. A different origin set with set_ncc_model_origin is not taken into account. The model has to lie completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that rounding effects can cause matches to lie up to \(0.5 \ast 2^{\text{NumLevels} - 1}\) pixels outside the image. The input Image can contain a single image object or an image object array containing multiple image objects. If Image contains a single image object, its domain is used as the region of interest for all models in ModelIDs. If Image contains multiple image objects, each domain is used as the region of interest for the corresponding model in ModelIDs. In this case, the images have to be identical except for their domains, i.e., Image cannot be constructed in an arbitrary manner using concat_obj, but must be created from the same image using add_channels or equivalent calls. If this is not the case, an error message is returned.

AngleStart and AngleExtent: The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with create_ncc_model. Furthermore, it should be noted that in some cases instances with a rotation that is slightly outside the specified range of rotations are found. This may happen if the specified range of rotations is smaller than the range given when the model was created.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see NumLevels), it might happen that instances with a score slightly below MinScore are found.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0. If NumMatches contains one element, find_ncc_models returns the best NumMatches instances of the model irrespective of the type of the model. If, for example, two models are passed in ModelIDs and NumMatches = 2 is selected, it can happen that two instances of the first model and no instances of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, NumMatches contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in NumMatches. If, for example, NumMatches = \([1, 1]\) is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap, only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.
If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

**SubPixel:** The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'false' the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`. If `SubPixel` is set to 'true', the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function.

**NumLevels:** The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the NCC model was created with `create_ncc_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_ncc_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_ncc_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_ncc_model_params` and then use a slightly lower value in `find_ncc_models`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, `NumLevels` must contain twice the number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, `NumLevels = [5, 2, 4, 1]` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit specification of the number of pyramid levels for the two models.

### Output parameters in detail

**Row, Column and Angle:** The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The coordinates `Row` and `Column` are the coordinates of the origin of the NCC model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin can be set with `set_ncc_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_ncc_model` shows how to create this matrix and use it to display the model at the found position in the search image and to calculate the exact coordinates.

Note also that for visualizing the model at the found position, also the procedure `dev_display_ncc_matching_results` can be used.

**Score:** Additionally, the score of each found instance is returned in `Score`.

**Model:** The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to `|ModelIDs| - 1`. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`.
Specifying a timeout

Using the operator `set_ncc_model_param` you can specify a 'timeout' for `find_ncc_models`. If the NCC models referenced by `ModelIDs` hold different values for 'timeout', `find_ncc_models` uses the smallest one. If `find_ncc_models` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by correlation-based matching, we highly recommend the usage of the procedure `dev_display_ncc_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

---

Attention

Note that the internally used memory increases with the number of used threads.

---

Parameters

- **Image** (input_object) ....... (multichannel-)imaget-array) \(\sim\) object : byte / uint2
  Input image in which the model should be found.

- **ModelIDs** (input_control) ...... ncc_model(-array) \(\sim\) handle
  Handle of the models.

- **AngleStart** (input_control) ....... angle.rad(-array) \(\sim\) real
  Smallest rotation of the models.
  Default value: -0.39
  Suggested values: \(\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)

- **AngleExtent** (input_control) ....... angle.rad(-array) \(\sim\) real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: \(\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)
  Restriction: AngleExtent \(\geq 0\)

- **MinScore** (input_control) ....... real(-array) \(\sim\) real
  Minimum score of the instances of the models to be found.
  Default value: 0.8
  Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) ....... integer(-array) \(\sim\) integer
  Number of instances of the models to be found (or 0 for all matches).
  Default value: 1
  Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)

- **MaxOverlap** (input_control) ....... real(-array) \(\sim\) real
  Maximum overlap of the instances of the models to be found.
  Default value: 0.5
  Suggested values: \(\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MaxOverlap} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **SubPixel** (input_control) ....... string(-array) \(\sim\) string
  Subpixel accuracy if not equal to 'none'.
  Default value: 'true'
  List of values: SubPixel \(\in\) {'false', 'true'}

- **NumLevels** (input_control) ....... integer(-array) \(\sim\) integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\))
  Default value: 0
  List of values: \(\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}\)

- **Row** (output_control) ....... point.y-array \(\sim\) real
  Row coordinate of the found instances of the models.
\[ \text{Column (output\_control)} \quad \text{Column coordinate of the found instances of the models.} \]
\[ \text{Angle (output\_control)} \quad \text{Rotation angle of the found instances of the models.} \]
\[ \text{Score (output\_control)} \quad \text{Score of the found instances of the models.} \]
\[ \text{Model (output\_control)} \quad \text{Index of the found instances of the models.} \]

---

Example

```
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_ncc_model (ImageReduced1, 'auto', rad(-45), rad(90), 'auto',
     'use_polarity', ModelID1)
create_ncc_model (ImageReduced2, 'auto', rad(-45), rad(90), 'auto',
     'use_polarity', ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_ncc_models (Image, ModelIDs, rad(-45), rad(90), 0.7, [1,1], 0.5,
     'true', 0, Row, Column, Angle, Score, Model)
dev_display_ncc_matching_results (ModelIDs, 'red', Row, Column,
     Angle, Model)
```

---

Result

If the parameter values are correct, the operator `find_ncc_models` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system` ('no_object_result',<Result>). If necessary, an exception is raised.

---

Execution Information

- Supports OpenCL compute devices.

---

`get_ncc_model_origin ( : : ModelID : Row, Column )`

Return the origin (reference point) of an NCC model.

The operator `get_ncc_model_origin` returns the origin (reference point) of the NCC model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. Hence, an origin of (0,0) means that the center of gravity of the domain
of the model image is used as the origin. An origin of (-20, -40) means that the origin lies to the upper left of the center of gravity.

**Parameters**

- **ModelID** (input_control) .......................... ncc_model ～ handle
  Handle of the model.
- **Row** (output_control) ............................. point.y ～ real
  Row coordinate of the origin of the NCC model.
- **Column** (output_control) .......................... point.x ～ real
  Column coordinate of the origin of the NCC model.

**Result**

If the handle of the model is valid, the operator `get_ncc_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

```
get_ncc_model_params ( : : ModelID : NumLevels, AngleStart,
                      AngleExtent, AngleStep, Metric )
```

Return the parameters of an NCC model.

The operator `get_ncc_model_params` returns the parameters of the NCC model `ModelID` that were used to create it using `create_ncc_model`. In particular, this output can be used to check the parameters `NumLevels` and `AngleStep` if they were determined automatically during the model creation with `create_ncc_model`. Furthermore, this output can be used to check the parameters if the model was read with `read_ncc_model`.

**Parameters**

- **ModelID** (input_control) .......................... ncc_model ～ handle
  Handle of the model.
- **NumLevels** (output_control) ......................... integer ～ integer
  Number of pyramid levels.
- **AngleStart** (output_control) ...................... angle.rad ～ real
  Smallest rotation of the pattern.
- **AngleExtent** (output_control) ..................... angle.rad ～ real
  Extent of the rotation angles.
  **Assertion:** AngleExtent ≥ 0
- **AngleStep** (output_control) ....................... angle.rad ～ real
  Step length of the angles (resolution).
  **Assertion:** AngleStep ≥ 0
- **Metric** (output_control) .......................... string ～ string
  Match metric.

### get_ncc_model_region ( : ModelRegion : ModelID ; )

Return the region used to create an NCC model.

The operator `get_ncc_model_region` returns the region used to create the NCC model `ModelID` in `ModelRegion`. This region can be used, for example, to visualize the found instances of the model in an image. It should be noted that the position of `ModelRegion` is normalized such that the reference point of the model (see `set_ncc_model_origin`) lies at the pixel position (0, 0). Hence, the region simply needs to be translated to the found position in the image (and possibly rotated around this point). `get_ncc_model_region` ignores the value of the system parameter `clip_region`.

### read_ncc_model ( : FileName : ModelID )

Read an NCC model from a file.

The operator `read_ncc_model` reads an NCC model, which has been written with `write_ncc_model`, from the file `FileName`. The default HALCON file extension for the NCC model is ‘ncm’.
### CHAPTER 18 MATCHING

**Parameters**

- **FileName** (input_control) .................................................. filename.read  \(\rightarrow\) string
  
  File name.

  **File extension:** .ncm

- **ModelID** (output_control) .................................................. ncc_model  \(\rightarrow\) handle
  
  Handle of the model.

**Result**

If the file name is valid, the operator `read_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

---

**serialize_ncc_model** ( : : ModelID : SerializedItemHandle )

Serializes an NCC model.

`serialize_ncc_model` serializes the data of an NCC model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ncc_model` is converted to a serialized item. The NCC model is defined by the handle `ModelID`. The serialized NCC model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ncc_model`.

**Parameters**

- **ModelID** (input_control) .................................................. ncc_model  \(\rightarrow\) handle
  
  Handle of the model.

- **SerializedItemHandle** (output_control) .................................. serialized_item  \(\rightarrow\) handle
  
  Handle of the serialized item.

**Result**

If the parameters are valid, the operator `serialize_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

HALCON/HDevelop Reference Manual, 2020-11-10
18.2. CORRELATION-BASED

```plaintext
set_ncc_model_origin ( : : ModelID, Row, Column : )
```

Set the origin (reference point) of an NCC model.

The operator `set_ncc_model_origin` sets the origin (reference point) of the NCC model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

**Parameters**

- **ModelID** (input_control) 
  Handle of the model.
- **Row** (input_control) 
  Row coordinate of the origin of the NCC model.
- **Column** (input_control) 
  Column coordinate of the origin of the NCC model.

**Result**

If the handle of the model is valid, the operator `set_ncc_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

**Module**

Matching

```plaintext
set_ncc_model_param ( : : ModelID, GenParamName, GenParamValue : )
```

Set selected parameters of the NCC model.

The operator `set_ncc_model_param` sets the selected parameters `GenParamName` in the NCC model `ModelID`. The following parameters can be modified:

- **'timeout'**

Sets the maximum runtime of the operators used to find the NCC model `ModelID` (using `find_ncc_model`). This is especially useful in cases where a maximum cycle time has to be ensured. The 'timeout' must be given in milliseconds. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the 'timer_mode' set via `set_system`. Be aware that the runtime of the search increases by up to 10 percent with activated timeout. To disable the timeout you can either use a negative value or 'false'.
CHAPTER 18 MATCHING

Parameters

▷ ModelID (input_control) ncc_model ~ handle
  Handle of the model.
▷ GenParamName (input_control) attribute.name-array ~ string
  Parameter names.
  List of values: GenParamName ∈ {'timeout'}
▷ GenParamValue (input_control) attribute.value-array ~ real / integer / string
  Parameter values.

If the parameters are valid, the operator set_ncc_model_param returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

write_ncc_model ( : : ModelID, FileName : )

Write an NCC model to a file.

The operator write_ncc_model writes an NCC model to the file FileName. The model can be read again with read_ncc_model. The default HALCON file extension for the NCC model is ’ncm’.

Parameters

▷ ModelID (input_control) ncc_model ~ handle
  Handle of the model.
▷ FileName (input_control) filename.write ~ string
  File name.
  File extension: .ncm

If the file name is valid (write permission), the operator write_ncc_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

18.3 Deformable

**clear_deformable_model ( ModelID : )**

Free the memory of a deformable model.

The operator `clear_deformable_model` frees the memory of a deformable model that was created by `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model`. After calling `clear_deformable_model`, the deformable model can no longer be used. The handle `ModelID` becomes invalid.

**Parameters**

- **ModelID (input_control)**: deformable_model(-array) → handle
  Handle of the model.

**Result**

If the parameters are valid, the operator `clear_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**create_local_deformable_model ( Template : NumLevels,**

- `AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,**
- `ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,**
- `Metric, Contrast, MinContrast, GenParamName,**
- `GenParamValue : ModelID )**

Creates a deformable model for local, deformable matching.

The operator `create_local_deformable_model` prepares a template, which is passed in the image `Template`, as a deformable model used for local deformable matching. The ROI of the model is passed as the domain of `Template`.

The local deformable matching can be used to detect an object that is distorted by a local deformation. This is similar to `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model` which require that the object is rigid. Further, it is an alternative to the mode 'max_deformation' in `find_shape_model`. Here, the model remains rigid but is able to tolerate small deformations. In contrast to `find_shape_model`, `create_local_deformable_model` can be used to estimate the deformation and rectify the image area where the object is found. Further, `create_local_deformable_model` can cope with bigger deformations.

As described in `create_planar_uncalib_deformable_model`, the origin (reference point) of the model is defined as the center of gravity of the domain (region) of the model image `Template`. Further, the axis-aligned
enclosing rectangle of the domain of the Template is used to determine the area of the search image that is rectified in calls of find_local_deformable_model.

For further explanation on the parameters used for the creation of a local deformable model we refer to the description of create_planar_uncalib_deformable_model. Note, that the parameters of the actual deformation are set with the call of find_local_deformable_model.

Parameters

- **Template** (input_object) ........................................ (multichannel-)image  ~ object : byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) ........................................ integer  ~ integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: NumLevels ∈ ['auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

- **AngleStart** (input_control) ......................................... angle.rad-array  ~ real
  This parameter is not used.
  Default value: []

- **AngleExtent** (input_control) .......................................... angle.rad-array  ~ real
  This parameter is not used.
  Default value: []

- **AngleStep** (input_control) ........................................... angle.rad  ~ real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]
  Restriction: AngleStep > 0 && AngleStep <= pi / 16

- **ScaleRMin** (input_control) .......................................... number  ~ real
  Minimum scale of the pattern in row direction.
  Default value: 1.0
  Suggested values: ScaleRMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: ScaleRMin > 0

- **ScaleRMax** (input_control) ........................................... number-array  ~ real
  This parameter is not used.
  Default value: []

- **ScaleRStep** (input_control) .......................................... number  ~ real / string
  Scale step length (resolution) in row direction.
  Default value: 'auto'
  Suggested values: ScaleRStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleRStep >= 0

- **ScaleCMin** (input_control) .......................................... number  ~ real
  Minimum scale of the pattern in column direction.
  Default value: 1.0
  Suggested values: ScaleCMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: ScaleCMin > 0

- **ScaleCMax** (input_control) ........................................... number-array  ~ real
  This parameter is not used.
  Default value: []

- **ScaleCStep** (input_control) .......................................... number  ~ real / string
  Scale step length (resolution) in column direction.
  Default value: 'auto'
  Suggested values: ScaleCStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleCStep >= 0

- **Optimization** (input_control) ....................................... string(-array)  ~ string
  Kind of optimization used for generating the model.
  Default value: 'none'
  List of values: Optimization ∈ ['auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high']
18.3. DEFORMABLE

- **Metric** (input_control) .................................................. string ~ string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric ∈ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}

- **Contrast** (input_control) ............................................. number-array ~ integer / string
  Thresholds or hysteresis thresholds for the contrast of the object in the template image.
  Default value: 'auto'
  Suggested values: Contrast ∈ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}

- **MinContrast** (input_control) ................................. number ~ integer / string
  Minimum contrast of the objects in the search images.
  Default value: 'auto'
  Suggested values: MinContrast ∈ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}

- **GenParamName** (input_control) ................................. string-array ~ string
  The generic parameter names.
  Default value: []
  List of values: GenParamName ∈ {[], 'min_size', 'part_size'}

- **GenParamValue** (input_control) .............................. integer-array ~ integer / real / string
  Values of the generic parameters.
  Default value: []
  List of values: GenParamValue ∈ {[], 'small', 'medium', 'big'}

- **ModelID** (output_control) ......................................... deformable_model ~ handle
  Handle of the model.

**Result**

If the parameters are valid, the operator `create_local_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Predecessors**

  `get_deformable_model_contours`, `find_local_deformable_model`,
  `get_deformable_model_params`, `write_deformable_model`,
  `clear_deformable_model`

**Alternatives**

- `read_deformable_model`

**See also**

- `create_planar_uncalib_deformable_model`, `create_planar_calib_deformable_model`

**Module**

**Prepare a deformable model for local deformable matching from XLD contours.**

```
create_local_deformable_model_xld ( Contours : : NumLevels,
                   AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,
                   ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,
                   Metric, MinContrast, GenParamName, GenParamValue : ModelID )
```
The operator `create_local_deformable_model_xld` creates a deformable model used for local deformable matching from the XLD contours passed in `Contours`. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator `create_local_deformable_model`, which creates a deformable model from a template image, the operator `create_local_deformable_model_xld` creates the deformable model from XLD contours.

The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_deformable_model_origin`.

For further explanation on the deformable model and its parameters we refer to the description of `create_planar_uncalib_deformable_model` and `create_local_deformable_model`. Note that `set_local_deformable_model_metric` can be used to change the metric of the model.

---

**Parameters**

- **Contours** (input_object) `xld_cont(-array) ~ object`
  Input contours that will be used to create the model.

- **NumLevels** (input_control) `integer ~ integer / string`
  Maximum number of pyramid levels.
  Default value: `'auto'`
  List of values: `NumLevels ∈ ['auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]`

- **AngleStart** (input_control) `angle.rad-array ~ real`
  This parameter is not used.
  Default value: `[]`

- **AngleExtent** (input_control) `angle.rad-array ~ real`
  This parameter is not used.
  Default value: `[]`

- **AngleStep** (input_control) `angle.rad ~ real / string`
  Step length of the angles (resolution).
  Default value: `'auto'`
  Suggested values: `AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]`
  Restriction: `AngleStep > 0 && AngleStep <= pi / 16`

- **ScaleRMin** (input_control) `number ~ real`
  Minimum scale of the pattern in row direction.
  Default value: `1.0`
  Suggested values: `ScaleRMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  Restriction: `ScaleRMin > 0`

- **ScaleRMax** (input_control) `number-array ~ real`
  This parameter is not used.
  Default value: `[]`

- **ScaleRStep** (input_control) `number ~ real / string`
  Scale step length (resolution) in row direction.
  Default value: `'auto'`
  Suggested values: `ScaleRStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]`
  Restriction: `ScaleRStep > 0`

- **ScaleCMin** (input_control) `number ~ real`
  Minimum scale of the pattern in column direction.
  Default value: `1.0`
  Suggested values: `ScaleCMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  Restriction: `ScaleCMin > 0`

- **ScaleCMax** (input_control) `number-array ~ real`
  This parameter is not used.
  Default value: `[]`
18.3. DEFORMABLE

- **ScaleCStep** (input_control) ................................. number \(\sim real / string\)
  Scale step length (resolution) in column direction.
  **Default value:** "auto"
  **Suggested values:** ScaleCStep \(\in\) \{'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2\}
  **Restriction:** ScaleCStep \(> 0\)

- **Optimization** (input_control) .............................. string(-array) \(\sim string\)
  Kind of optimization used for generating the model.
  **Default value:** "auto"
  **List of values:** Optimization \(\in\) \{'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'\}

- **Metric** (input_control) ................................. string \(\sim string\)
  Match metric.
  **Default value:** 'ignore_local_polarity'
  **List of values:** Metric \(\in\) \{'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'\}

- **MinContrast** (input_control) ................................. number \(\sim integer\)
  Minimum contrast of the objects in the search images.
  **Default value:** 5
  **Suggested values:** MinContrast \(\in\) \{1, 2, 3, 5, 7, 10, 20, 30, 40\}

- **GenParamName** (input_control) ........................ string-array \(\sim string\)
  The generic parameter names.
  **Default value:** []
  **List of values:** GenParamName \(\in\) \[['part_size']\]

- **GenParamValue** (input_control) ........................ integer-array \(\sim integer / real / string\)
  Values of the generic parameters.
  **Default value:** []
  **List of values:** GenParamValue \(\in\) \[['small', 'medium', 'big']\]

- **ModelID** (output_control) .............................. deformable_model \(\sim handle\)
  Handle of the model.

---

If the parameters are valid, the operator `create_local_deformable_model_xld` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Module**

Matching
Create a deformable model for calibrated perspective matching.

The operator `create_planar_calib_deformable_model` prepares a template, which is passed in the image `Template`, as a deformable model used for planar calibrated matching. The ROI of the model is passed as the domain of `Template`.

The planar calibrated matching can be used to detect the 3D pose of a planar object or planar subparts of non-planar objects that are distorted by a projective view. This is an alternative to `create_planar_uncalib_deformable_model`, which returns the position as a 2D projective transformation (homography), but not as a metric 3D pose.

In order to determine the 3D pose, the internal camera parameters `CamParam` must be provided. Typically, the internal parameters are determined with the help of `calibrate_cameras`.

Additionally to the internal camera parameters, the metric size of the image part that is passed in `Template` must be known. For this, a 3D reference pose that defines a 3D model plane in which the object resides must be provided with `ReferencePose`. The 3D model plane is spanned by the x and y axis of the coordinate system defined by `ReferencePose`.

As described in `create_planar_uncalib_deformable_model`, the origin (reference point) of the model is defined as the center of gravity of the domain (region) of the model image `Template`. This image point defines a ray that is cut with the plane that is provided with `ReferencePose` to obtain the absolute 3D model pose. This is also the absolute pose that is later returned in `find_planar_calib_deformable_model`. Hence, the 3D pose of the model might differ from the reference pose by a 2D translation in the model plane. The final model pose can be determined by calling `get_deformable_model_params`. The 3D model plane can be estimated by using `calibrate_cameras` or `vector_to_pose`. For consistency of the coordinate systems, the `ReferencePose` should be aligned as if a calibration plate would be put onto the object.

For further explanation on the planar deformable model and its parameters we refer to the description of `create_planar_uncalib_deformable_model`.

---

**Parameters**

- **Template** *(input_object)* (multichannel-)image ➔ object : byte / uint2
  Input image whose domain will be used to create the model.

- **CamParam** *(input_control)* campar ➔ real / integer / string
  The parameters of the internal orientation of the camera.

- **ReferencePose** *(input_control)* pose ➔ real / integer
  The reference pose of the object in the reference image.

- **NumLevels** *(input_control)* integer ➔ integer / string
  Maximum number of pyramid levels.
  Default value: ‘auto’

Matching

---

```cpp
create_planar_calib_deformable_model_xld ( 
  Contours : : CamParam, ReferencePose, NumLevels, AngleStart, 
  AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep, 
  ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, 
  MinContrast, GenParamName, GenParamValue : ModelID )
```

Prepare a deformable model for planar calibrated matching from XLD contours.

The operator `create_planar_calib_deformable_model_xld` creates a deformable model used for planar calibrated matching from the XLD contours passed in `Contours`. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator `create_planar_calib_deformable_model`, which creates a deformable model from a template image, the operator `create_planar_calib_deformable_model_xld` creates the deformable model from XLD contours. Note that the operator expects `Contours` to be in a metric world coordinate system. This is in contrast to `create_planar_uncalib_deformable_model_xld`, where the `Contours` are provided in image coordinates.

Further, the origin (reference point) of the model is taken directly from the provided `Contours`. This is in contrast to `create_planar_uncalib_deformable_model_xld`, where the center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used. A different origin in the world coordinate system can be set with `set_deformable_model_origin`.

For further explanation on the planar deformable model and its parameters we refer to the description of `create_planar_uncalib_deformable_model` and `create_planar_calib_deformable_model`.

**Attention**

Note that, in contrast to the operator `create_planar_calib_deformable_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated before calling `create_planar_calib_deformable_model_xld` with the operator `select_contours_xld`.

**Parameters**

- **Contours** (input_object) .........................xld_cont(-array) ~ object
  Input contours that will be used to create the model.

- **CamParam** (input_control) ......................campar ~ real / integer / string
  The parameters of the internal orientation of the camera.
18.3. DEFORMABLE

- ReferencePose (input_control) ...................................... pose \(\sim\) real / integer
  The reference pose of the object.

- NumLevels (input_control) ........................................... integer \(\sim\) integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: NumLevels \(\in\) \{'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

- AngleStart (input_control) ........................................... angle.rad-array \(\sim\) real
  This parameter is not used.
  Default value: []

- AngleExtent (input_control) ......................................... angle.rad-array \(\sim\) real
  This parameter is not used.
  Default value: []

- AngleStep (input_control) .......................................... angle.rad \(\sim\) real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: AngleStep \(\in\) \{'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\}
  Restriction: AngleStep \(> 0\) \&\& AngleStep \(< \pi / 16\)

- ScaleRMin (input_control) ........................................... number \(\sim\) real
  Minimum scale of the pattern in row direction.
  Default value: 1.0
  Suggested values: ScaleRMin \(\in\) \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  Restriction: ScaleRMin \(> 0\)

- ScaleRMax (input_control) .......................................... number-array \(\sim\) real
  This parameter is not used.
  Default value: []

- ScaleRStep (input_control) .......................................... number \(\sim\) real / string
  Scale step length (resolution) in row direction.

Module

create_planar_uncalib_deformable_model ( Template : : NumLevels,
AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,
ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,
Metric, Contrast, MinContrast, GenParamName,
GenParamValue : ModelID )

Creates a deformable model for uncalibrated, perspective matching.

The operator create_planar_uncalib_deformable_model prepares a template, which is passed in the image Template, as a deformable model used for uncalibrated perspective matching. The ROI of the model is passed as the domain of Template.

The planar uncalibrated matching can be used to detect planar objects or planar subparts of non-planar objects that are distorted by a projective view.

This is an alternative to create_shape_model, create_scaled_shape_model and create_aniso_shape_model, where typically the search image must be rectified by calibrate_cameras and gen_image_to_world_plane_map beforehand.

In contrast to create_shape_model_3d there is no need to pre-generate different views of an object, resulting into a smaller memory consumption. Hence, in case of a planar perspectively distorted object, create_planar_uncalib_deformable_model should be preferred.

The model is generated using multiple image pyramid levels and is stored in memory. The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_planar_uncalib_deformable_model.

Input parameters in detail
**NumLevels:** The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_planar_uncalib_deformable_model` returns with an error message. If `NumLevels` is set to 'auto', `create_planar_uncalib_deformable_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_deformable_model_params`. In rare cases, it might happen that `create_planar_uncalib_deformable_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in `find_planar_uncalib_deformable_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_planar_uncalib_deformable_model` increases. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

**Angle and Scale parameters:** Note that the parameters `AngleStart`, `AngleExtent`, `ScaleRMax`, and `ScaleCMax` are not used by this operator. Instead, they have to be specified within the operator `find_planar_uncalib_deformable_model`. `ScaleRMin` and `ScaleCMin` can be relevant if you expect matches that are smaller than in the original image `Template`. Then, if `NumLevels` is set to 'auto', the number of used pyramid levels may decrease. Generally, the parameters `AngleStep`, `ScaleRStep`, and `ScaleCStep` can be determined automatically. The automatically computed angle and scale step lengths can be queried using `get_deformable_model_params`. For more information about how these parameters work, please refer to the operator `find_planar_uncalib_deformable_model`.

**Optimization:** For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from 'none'. If `Optimization` = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_planar_uncalib_deformable_model` to set the parameter Score and Greediness to a smaller value. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined. If `Optimization` is set to 'auto', `create_planar_uncalib_deformable_model` automatically determines the reduction of the number of model points.

**Contrast:** The parameter `Contrast` determines the contrast the model points (edges) must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model. The following values can be set for `Contrast`:

- A single contrast value. You can set:
  - an integer value: the manually determined value is used.
  - 'auto_contrast': the contrast value is computed automatically.

- Hysteresis thresholds. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. For more information about the hysteresis threshold method, see `hysteresis_threshold`. You can set:
  - A tuple of two values: The first value determines the lower threshold, the second value determines the upper threshold.
  - 'auto' (default value) or 'auto_contrast_hyst': The hysteresis thresholds are computed automatically.

In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_deformable_model_params` and subsequently verified using `inspect_shape_model` before calling `create_planar_uncalib_deformable_model`. Note...
that MinContrast influences the automatic contrast estimation, and hence also the estimation of the minimum size.

**MinContrast:** With MinContrast, it can be determined which minimal contrast the model must have in the recognition performed by find_planar_uncalib_deformable_model. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. Obviously, MinContrast must be smaller than Contrast. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_planar_uncalib_deformable_model. If MinContrast is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using get_deformable_model_params. The MinContrast of a deformable model can later be changed with the help of set_deformable_model_param.

**Metric:** The parameter Metric determines the conditions under which the model is recognized in the image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_planar_uncalib_deformable_model will increase slightly in this case. If Metric = 'ignore_part_polarity', the contrast polarity is allowed to change only between different parts of the model, whereas the polarity of model points that are within the same model part must not change. Please note that the term 'ignore_part_polarity' is capable of being misunderstood. It means that polarity changes between neighboring model parts do not influence the score, and hence are ignored. If Metric = 'ignore_local_polarity', the model is found even if the contrast changes for each individual model point. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. In this case the runtime of find_planar_uncalib_deformable_model increases significantly. The above four metrics can only be applied to single-channel images. If a multi-channel image is used as the model image or as the search image only the first channel will be used (and no error message will be returned). If Metric = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of find_planar_uncalib_deformable_model can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for Metric = 'ignore_color_polarity' the number of channels in the model creation with create_planar_uncalib_deformable_model and in the search with find_planar_uncalib_deformable_model can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

**GenParamName, GenParamValue:** With the help of the generic parameters GenParamName and GenParamValue, the user can set parameters for the deformable model generation that are needed only in rare cases. Currently, it is used to adapt the average size of the sub-parts that the deformable model should consist of. Here, GenParamName should be set to 'part_size' and GenParamValue should be set to 'small', 'medium' or 'big'. For objects that consist of many small contours, 'small' should be selected. For objects that consist of only big contours, 'big' should be set. The default value of this parameter is 'big'. Optionally, GenParamName = 'min_size' can determine a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size specified in the corresponding GenParamValue are suppressed. This threshold for the minimum size is divided by two for each successive pyramid level. 'min_size' can be set to an arbitrary integer value greater or equal 0. It can also be set to 'auto' which means that the minimum size will be determined automatically. The default value of this parameter is 'auto'.

HALCON/HDevelop Reference Manual, 2020-11-10
The center of gravity of the domain (region) of the model image Template is used as the origin (reference point) of the model. A different origin for the model can be set with set_deformable_model_origin.

create_planar_uncalib_deformable_model_xld (Contours : : NumLevels, AngleStart, AngleExtent, AngleStep,
ScaleRMin, ScaleRMax, ScaleRStep, ScaleCMin, ScaleCMax,
ScaleCStep, Optimization, Metric, MinContrast, GenParamName,
GenParamValue : ModelID )

Prepare a deformable model for planar uncalibrated matching from XLD contours.
The operator create_planar_uncalib_deformable_model_xld creates a deformable model used for planar uncalibrated matching from the XLD contours passed in Contours. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator create_planar_uncalib_deformable_model, which creates a deformable model from a template image, the operator create_planar_uncalib_deformable_model_xld creates the deformable model from XLD contours.
The model is generated for multiple image pyramid levels and is stored in memory. The center of gravity of the smallest surrounding rectangle of the Contours that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with set_deformable_model_origin. The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_planar_uncalib_deformable_model.

Some Input parameters in detail

**NumLevels**: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure leads to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_planar_uncalib_deformable_model_xld returns with an error message. If NumLevels is set to 'auto', create_planar_uncalib_deformable_model_xld determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using get_deformable_model_params. In rare cases, it might happen that create_planar_uncalib_deformable_model_xld determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the search image or it may be necessary to select very low parameters for MinScore or Greediness in find_planar_uncalib_deformable_model to find the object. If the number of pyramid levels is chosen too small, the time required to find the object with find_planar_uncalib_deformable_model may increase. In both cases, the number of pyramid levels should be selected manually.

**Angle and Scale parameters**: Note that the parameters AngleStart, AngleExtent, ScaleRMax, and ScaleCMax are not used by this operator. Instead, they have to be specified within the operator find_planar_uncalib_deformable_model. ScaleRMin and ScaleCMin can be relevant if you expect matches that are smaller than the given XLD Contours. Then, if NumLevels is set to 'auto', the number of used pyramid levels may decrease. Generally, the parameters AngleStep, ScaleRStep and ScaleCStep can be determined automatically. The automatically computed angle and scale step lengths can be queried using get_deformable_model_params. For more information about how these parameters work, please refer to the operator find_planar_uncalib_deformable_model.

**Optimization**: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none' is set, all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_planar_uncalib_deformable_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search, because in this case usually significantly more potential instances of the model must be examined. If Optimization is set to 'auto', create_planar_uncalib_deformable_model_xld automatically determines the reduction of the number of model points.

**MinContrast**: With MinContrast, it can be determined which contrast the object contours must at least have in the recognition performed by find_planar_uncalib_deformable_model. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray-value changes caused by the noise in the image. If, e.g., the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multi-channel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see below) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, e.g., the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image, MinContrast should be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise to ensure that the position and rotation of the model are extracted robustly and accurately by find_planar_uncalib_deformable_model.

**Metric**: The parameter Metric determines the conditions under which the model is recognized in the image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the
The runtime of `find_planar_uncalib_deformable_model` will increase slightly in this case. If `Metric = 'ignore_part_polarity'` or `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. These modes can, e.g., be useful if the object consists of a part with a medium gray value, within which either darker or brighter sub-objects lie. The above mentioned four metrics can only be applied to single-channel images. If a multi-channel image is used as the search image, only the first channel will be used (and no error message will be returned). If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, e.g., the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_planar_calib_deformable_model` can also increase significantly. The metric `ignore_color_polarity` can be used for images with an arbitrary number of channels. If it is used for single-channel images, it has the same effect as `ignore_local_polarity`. It should be noted that for `Metric = 'ignore_color_polarity'` the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, e.g., also contain images of the same object that were obtained by illuminating the object from different directions. Note that the first two metrics (`use_polarity` and `ignore_global_polarity`) can only be selected if all `Contours` provide the attribute `edge_direction`, which defines the polarity of the contained contours. For more information about contour attributes like `edge_direction` see get_contour_attrib_xld. Otherwise, these two metrics can be selected with the operator `set_planar_uncalib_deformable_model_metric`, which determines the polarity of the model contours from a representative image.

---

**Attention**

Note that, in contrast to the operator `create_planar_uncalib_deformable_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated before calling `create_planar_uncalib_deformable_model_xld` with the operator `select_contours_xld`.

---

**Parameters**

- **Contours (input_object)**: `xld_cont(-array) ~ object`
  Input contours that will be used to create the model.

- **NumLevels (input_control)**: `integer ~ integer / string`
  Maximum number of pyramid levels.
  
  **Default value**: 'auto'
  
  **Suggested values**: `NumLevels ∈ ['auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]`

- **AngleStart (input_control)**: `angle.rad-array ~ real`
  This parameter is not used.
  
  **Default value**: []

- **AngleExtent (input_control)**: `angle.rad-array ~ real`
  This parameter is not used.
  
  **Default value**: []

- **AngleStep (input_control)**: `angle.rad ~ real / string`
  Step length of the angles (resolution).
  
  **Default value**: 'auto'
  
  **Suggested values**: `AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]`
  
  **Restriction**: `AngleStep > 0 && AngleStep <= pi / 16`

- **ScaleRMin (input_control)**: `number ~ real`
  Minimum scale of the pattern in row direction.
  
  **Default value**: 1.0
  
  **Suggested values**: `ScaleRMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  
  **Restriction**: `ScaleRMin > 0`

- **ScaleRMax (input_control)**: `number-array ~ real`
  This parameter is not used.
  
  **Default value**: []

- **ScaleRStep (input_control)**: `number ~ real / string`
  Scale step length (resolution) in row direction.
  
  **Default value**: 'auto'
  
  **Suggested values**: `ScaleRStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]`
  
  **Restriction**: `ScaleRStep > 0`
18.3. DEFORMABLE

- **ScaleCMin** (input_control) .............................................. number ➞ real
  Minimum scale of the pattern in column direction.
  Default value: 1.0
  Suggested values: ScaleCMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: ScaleCMin > 0

- **ScaleCMax** (input_control) .............................................. number-array ➞ real
  This parameter is not used.
  Default value: []

- **ScaleCStep** (input_control) .............................................. number ➞ real / string
  Scale step length (resolution) in the column direction.
  Default value: 'auto'
  Suggested values: ScaleCStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleCStep > 0

- **Optimization** (input_control) ........................................... string(-array) ➞ string
  Kind of optimization used for generating the model.
  Default value: 'auto'
  List of values: Optimization ∈ ['auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high']

- **Metric** (input_control) ............................................... string ➞ string
  Match metric.
  Default value: 'ignore_local_polarity'
  List of values: Metric ∈ ['use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity']

- **MinContrast** (input_control) .......................................... number ➞ integer
  Minimum contrast of the objects in the search images.
  Default value: 5
  Suggested values: MinContrast ∈ [1, 2, 3, 5, 7, 10, 20, 30, 40]

- **GenParamName** (input_control) ....................................... string-array ➞ string
  The generic parameter names.
  Default value: []
  List of values: GenParamName ∈ [', part_size']

- **GenParamValue** (input_control) ....................................... integer-array ➞ integer / real / string
  Values of the generic parameters.
  Default value: []
  List of values: GenParamValue ∈ [', small', 'medium', 'big']

- **ModelID** (output_control) ................................................ deformable_model ➞ handle
  Handle of the model.

Result

If the parameters are valid, the operator create_planar_uncalib_deformable_model_xld returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised. If the parameter NumLevels is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

- read_contour_xld_dxf, edges_sub_pix, select_contours_xld

Possible Successors

**Description**

deserialize_deformable_model ( : : SerializedItemHandle : ModelID )

Deserializes a deformable model.

deserialize_deformable_model deserializes a deformable model, that was serialized by serialize_deformable_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized deformable model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created deformable model with the handle ModelID.

**Parameters**

- **SerializedItemHandle** (input_control): serialized_item ~ handle
  Handle of the serialized item.
- **ModelID** (output_control): deformable_model ~ handle
  Handle of the model.

**Result**

If the parameters are valid, the operator deserialize_deformable_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**ModuleName**

determine_deformable_model_params ( Template : : NumLevels, AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization, Metric, Contrast, MinContrast, GenParamName, GenParamValue, Parameters : ParameterName, ParameterValue )

Determine the parameters of a deformable model.

determine_deformable_model_params determines certain parameters of a deformable model automatically from the model image Template. The parameters to be determined can be specified with Parameters. determine_deformable_model_params can be used to determine the same parameters that are determined automatically when the respective parameter in create_planar_uncalib_deformable_model is set to 'auto': the number of pyramid levels (Parameters = 'num_levels'), the angle step length (Parameters = 'angle_step'), the scale step length (Parameters = 'scale_step' for isotropic scaling and 'scale_r_step' and/or 'scale_c_step' for anisotropic scaling), the kind of optimization (Parameters = 'optimization'), the threshold (Parameters = 'contrast') or the hysteresis thresholds (Parameters = 'contrast_hyst') for the contrast, the minimum size of the object parts (Parameters = 'min_size'), and the minimum contrast (Parameters =...
'min_contrast'). By passing a tuple of the above values in Parameters, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed. In this case both hysteresis thresholds are determined, i.e., the operator behaves like passing 'contrast_hyst' instead of 'contrast'.

determine_deformable_model_params is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in ParameterName and ParameterValue. The parameter names in ParameterName are identical to the names in Parameters, where, of course, the value 'all' is replaced by the actual parameter names. An exception is the parameter 'contrast_hyst', for which the two values 'contrast_low' and 'contrast_high' are returned.

The remaining parameters (NumLevels, AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization, Metric, Contrast, and MinContrast) have the same meaning as in create_planar_uncalib_deformable_model and find_planar_uncalib_deformable_model. The description of these parameters can be looked up with these operators. These parameters are used by determine_deformable_model_params to calculate the parameters to be determined in the same manner as in create_planar_uncalib_deformable_model. It should be noted that if the parameters of a deformable model with isotropic scaling should be determined, i.e., if Parameters contains 'scale_step' either explicitly or implicitly via 'all', the parameters ScaleMin and ScaleMax must contain one value each. If the parameters of a deformable model with anisotropic scaling should be determined, i.e., if Parameters contains 'scale_r_step' or 'scale_c_step' either explicitly or implicitly, the parameters ScaleMin and ScaleMax must contain two values each. In this case, the first value of the respective parameter refers to the scaling in row direction, while the second value refers to scaling in the column direction.

Note that in determine_deformable_model_params some parameters appear that can also be determined automatically (NumLevels, Optimization, Contrast, MinContrast). If these parameters should not be determined automatically, i.e., their name is not passed in ParameterName, the corresponding parameters must contain valid values and must not be set to 'auto'. In contrast, if these parameters are to be determined automatically, their values are treated in the following way: If the optimization or the (hysteresis) contrast is to be determined automatically, i.e., ParameterName contains the value 'optimization' or 'contrast' ('contrast_hyst'), the values passed in Optimization and Contrast are ignored. In contrast, if the maximum number of pyramid levels or the minimum contrast is to be determined automatically, i.e., ParameterName contains the value 'num_levels' or 'min_contrast', you can let HALCON determine suitable values and at the same time specify an upper or lower boundary, respectively:

If the maximum number of pyramid levels should be specified in advance, NumLevels can be set to the particular value. If in this case Parameters contains the value 'num_levels', the computed number of pyramid levels is at most NumLevels. If NumLevels is set to 'auto' (or 0 for backwards compatibility), the number of pyramid levels is determined without restrictions as large as possible.

If the minimum contrast should be specified in advance, MinContrast can be set to the particular value. In this case Parameters contains the value 'min_contrast', the computed minimum contrast is at least MinContrast. If MinContrast is set to 'auto', the minimum contrast is determined without restrictions.

If the user wishes to create a calibrated, deformable model with create_planar_calib_deformable_model, the internal camera parameters are needed for the correct estimation of the parameters in ParameterValue. The camera parameters can be provided by setting GenParamName to 'cam_param' and providing the tuple containing the camera parameters in GenParamValue.

---

Parameters

- **Template** (input_object) .......................... (multichannel-)image \(\sim\) object : byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) .......................... integer \(\sim\) integer / string
  Maximum number of pyramid levels.
  
  Default value: 'auto'
  List of values: NumLevels \(\in\) ['auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

- **AngleStart** (input_control) .......................... angle.rad \(\sim\) real
  Smallest rotation of the model.
  
  Default value: -0.39
  Suggested values: AngleStart \(\in\) [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]
CHAPTER 18 MATCHING

- **AngleExtent** (input_control) .................................................... angle.rad $\sim$ real
  
  Extent of the rotation angles.
  
  Default value: 0.79
  
  Suggested values: $\text{AngleExtent} \in \{6.28, 3.14, 1.57, 0.79, 0.39\}$
  
  Restriction: $\text{AngleExtent} \geq 0$

- **ScaleMin** (input_control) ...................................................... number(-array) $\sim$ real
  
  Minimum scale of the model.
  
  Default value: 0.9
  
  Suggested values: $\text{ScaleMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
  
  Restriction: $\text{ScaleMin} > 0$

- **ScaleMax** (input_control) ..................................................... number(-array) $\sim$ real
  
  Maximum scale of the model.
  
  Default value: 1.1
  
  Suggested values: $\text{ScaleMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
  
  Restriction: $\text{ScaleMax} \geq \text{ScaleMin}$

- **Optimization** (input_control) .............................................. string $\sim$ string
  
  Kind of optimization.
  
  Default value: ‘auto’
  
  List of values: $\text{Optimization} \in \{\text{‘auto’, ‘none’, ‘point_reduction_low’, ‘point_reduction_medium’, ‘point_reduction_high’}\}$

- **Metric** (input_control) ....................................................... string $\sim$ string
  
  Match metric.
  
  Default value: ‘use_polarity’
  
  List of values: $\text{Metric} \in \{\text{‘use_polarity’, ‘ignore_global_polarity’, ‘ignore_local_polarity’, ‘ignore_color_polarity’}\}$

- **Contrast** (input_control) ..................................................... number(-array) $\sim$ integer / string
  
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
  
  Default value: ‘auto’
  
  Suggested values: $\text{Contrast} \in \{\text{‘auto’, ‘auto_contrast’, ‘auto_contrast_hyst’, ‘auto_min_size’, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}\}$

- **MinContrast** (input_control) ................................................ number $\sim$ integer / string
  
  Minimum contrast of the objects in the search images.
  
  Default value: ‘auto’
  
  Suggested values: $\text{MinContrast} \in \{\text{‘auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40}\}$
  
  Restriction: $\text{MinContrast} < \text{Contrast}$

- **GenParamName** (input_control) .......................................... string-array $\sim$ string
  
  The general parameter names.
  
  Default value: []
  
  List of values: $\text{GenParamName} \in \{\text{‘cam_param’}\}$

- **GenParamValue** (input_control) .......................................... number-array $\sim$ real / integer / string
  
  Values of the general parameter.
  
  Default value: []
  
  List of values: $\text{GenParamValue} \in \{\text{}\}$

- **Parameters** (input_control) .............................................. string(-array) $\sim$ string
  
  Parameters to be determined automatically.
  
  Default value: ‘all’
  

- **ParameterName** (output_control) ........................................ string-array $\sim$ string
  
  Name of the automatically determined parameter.

- **ParameterValue** (output_control) ...................................... number-array $\sim$ real / integer
  
  Value of the automatically determined parameter.

If the parameters are valid, the operator determine_deformable_model_params returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters NumLevels and Contrast are chosen such that the model contains too few points, or the input image does not contain a sufficient number of significant features, the error message 8510 is raised.
### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

#### Module

**Matching**

```plaintext
find_local_deformable_model { Image : ImageRectified, VectorField, DeformedContours : ModelID, AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, MinScore, NumMatches, MaxOverlap, NumLevels, Greediness, ResultType, GenParamName, GenParamValue : Score, Row, Column }
```

Find the best matches of a local deformable model in an image.

The operator `find_local_deformable_model` finds the best `NumMatches` instances of the locally deformable model `ModelID` in the input `Image`. The model must have been created previously by calling `create_local_deformable_model` or `read_deformable_model`.

The model is searched within those points of the domain of the image in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore`. Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^\text{NumLevels}-1$. This behavior can be changed with `set_system('border_shape_models','true')`, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels them model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^\text{NumLevels}-1$ using, e.g., `dilation_circle`.

The operator `find_local_deformable_model` returns the `Row` and `Column` coordinates of the found instances. Additionally, a rectified part of the image, the respective vector field, and the contours of the found deformed model instance can be returned in `ImageRectified`, `VectorField`, and `DeformedContours`. By default, these iconic objects are not returned. In case that they are needed the parameter `ResultType` should be set to ‘image_rectified’, ‘vector_field’ and ‘deformed_contours’. The size of `ImageRectified` and `VectorField` is the smallest axis-aligned rectangle of the domain of the image that was used to create the local deformable model with `create_local_deformable_model`. The size of the rectified image and the vector field can be expanded in all directions by setting `GenParamName` to ‘expand_border’ and the respective `GenParamValue` to the number of pixels. Optionally, a specific direction can be selected with ‘expand_border_top’, ‘expand_border_bottom’, ‘expand_border_left’, and ‘expand_border_right’. Please note that the returned `VectorField` is in absolute coordinates and can be used for `convert_map_type`.

The smoothness of the estimated deformation can be selected with `GenParamName` set to ‘deformation_smoothness’. The value for ‘deformation_smoothness’ can be imagined as the size of a smoothing filter to the estimated deformation field. A too small value expects a strong deformation a too big value expects a rigid object. The minimal value for ‘deformation_smoothness’ is 3, a typical value is 11, and the value can be increased further for only small global deformations.

Finally, the score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image.
For further explanation on the parameters used for the search of a local deformable model we refer to the description of `find_planar_uncalib_deformable_model`.

### Parameters

- **Image** (input_object) .................. (multichannel-image) \(\sim\) object: byte / uint2
  Input image in which the model should be found.

- **ImageRectified** (output_object) .......... (multichannel-image-array) \(\sim\) object: byte / uint2
  Rectified image of the found model.

- **VectorField** (output_object) ............ singlechannelimage-array \(\sim\) object: vector_field
  Vector field of the rectification transformation.

- **DeformedContours** (output_object) ........... xld_cont-array \(\sim\) object
  Contours of the found instances of the model.

- **ModelID** (input_control) ................. deformable_model \(\sim\) handle
  Handle of the model.

- **AngleStart** (input_control) ................. angle.rad \(\sim\) real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: \(\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)

- **AngleExtent** (input_control) ............... angle.rad \(\sim\) real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: \(\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)
  Restriction: \(\text{AngleExtent} \geq 0\)

- **ScaleRMin** (input_control) .................. number \(\sim\) real
  Minimum scale of the model in row direction.
  Default value: 1.0
  Suggested values: \(\text{ScaleRMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Restriction: \(\text{ScaleRMin} > 0\)

- **ScaleRMax** (input_control) .................. number \(\sim\) real
  Maximum scale of the model in row direction.
  Default value: 1.0
  Suggested values: \(\text{ScaleRMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)
  Restriction: \(\text{ScaleRMax} \geq \text{ScaleRMin}\)

- **ScaleCMin** (input_control) .................. number \(\sim\) real
  Minimum scale of the model in column direction.
  Default value: 1.0
  Suggested values: \(\text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Restriction: \(\text{ScaleCMin} > 0\)

- **ScaleCMax** (input_control) .................. number \(\sim\) real
  Maximum scale of the model in column direction.
  Default value: 1.0
  Suggested values: \(\text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)
  Restriction: \(\text{ScaleCMax} \geq \text{ScaleCMin}\)

- **MinScore** (input_control) .................. real \(\sim\) real
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) ................ integer \(\sim\) integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)
### MaxOverlap (input_control)  
Maximum overlap of the instances of the model to be found.

**Default value:** 1.0  
**Suggested values:** \( \text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)  
**Typical range of values:** \( 0 \leq \text{MaxOverlap} \leq 1 \)  
**Minimum increment:** 0.01  
**Recommended increment:** 0.05

### NumLevels (input_control)  
Number of pyramid levels used in the matching.

**Default value:** 0  
**List of values:** \( \text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\} \)

### Greediness (input_control)  
“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).

**Default value:** 0.9  
**Suggested values:** \( \text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)  
**Typical range of values:** \( 0 \leq \text{Greediness} \leq 1 \)  
**Minimum increment:** 0.01  
**Recommended increment:** 0.05

### ResultType (input_control)  
Switch for requested iconic result.

**Default value:** []  
**List of values:** \( \text{ResultType} \in \{[\], 'image_rectified', 'vector_field', 'deformed_contours'\} \)

### GenParamName (input_control)  
The general parameter names.

**Default value:** []  
**List of values:** \( \text{GenParamName} \in \{[\], 'subpixel', 'angle_step', 'scale_r_step', 'scale_c_step', 'deformation_smoothness', 'expand_border', 'expand_border_top', 'expand_border_bottom', 'expand_border_left', 'expand_border_right'\} \)

### GenParamValue (input_control)  
Values of the general parameters.

**Default value:** []  
**List of values:** \( \text{GenParamValue} \in \{[\], 'none', 'least_squares', 'least_squares_high', 'least_squares_very_high'\} \)

### Score (output_control)  
Scores of the found instances of the model.

### Row (output_control)  
Row coordinates of the found instances of the model.

### Column (output_control)  
Column coordinates of the found instances of the model.

---

If the parameters are valid, the operator `find_local_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

**Module**

HALCON 20.11.0.0
**find_planar_calib_deformable_model** ( Image : ModelID, 
  AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, 
  ScaleCMax, MinScore, NumMatches, MaxOverlap, NumLevels, 
  Greediness, GenParamName, GenParamValue : Pose, CovPose, Score )

Find the best matches of a calibrated deformable model in an image and return their 3D pose.

The operator **find_planar_calib_deformable_model** finds the best `NumMatches` instances of the calibrated deformable model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_planar_calib_deformable_model` or `read_deformable_model`. The operator **find_planar_calib_deformable_model** returns the 3D `Pose` of the found instances in the camera coordinate system.

Additionally, the accuracy of the six pose parameters are returned in `CovPose`. By default, `CovPose` contains the 6 standard deviations of the pose parameters for each match. If the generic parameter 'cov_pose_mode' was set to 'covariances', `CovPose` contains the 36 values of the complete 6 × 6 covariance matrix of the 6 pose parameters. Note that this reflects only an inner accuracy from which the real accuracy of the pose may differ. Finally, the score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image.

For further explanation on the planar deformable model and its parameters we refer to the description of **find_planar_uncalib_deformable_model**.

---

**Parameters**

- **Image** (input_object) ..................(multichannel-)image ～ object : byte / uint2
  Input image in which the model should be found.

- **ModelID** (input_control) ....................., deformable_model ～ handle
  Handle of the model.

- **AngleStart** (input_control) ....................angle.rad ～ real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: AngleStart ∈ {-3.14, -1.57, -0.78, -0.39, -0.20, 0.0}

- **AngleExtent** (input_control) ....................angle.rad ～ real
  Extent of the rotation angles.
  Default value: 0.78
  Suggested values: AngleExtent ∈ {6.29, 3.14, 1.57, 0.78, 0.39, 0.0}
  Restriction: AngleExtent >= 0

- **ScaleRMin** (input_control) ..................number ～ real
  Minimum scale of the model in row direction.
  Default value: 1.0
  Suggested values: ScaleRMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: ScaleRMin > 0

- **ScaleRMax** (input_control) ..................number ～ real
  Maximum scale of the model in row direction.
  Default value: 1.0
  Suggested values: ScaleRMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
  Restriction: ScaleRMax >= ScaleRMin

- **ScaleCMin** (input_control) ..................number ～ real
  Minimum scale of the model in column direction.
  Default value: 1.0
  Suggested values: ScaleCMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: ScaleCMin > 0

- **ScaleCMax** (input_control) ..................number ～ real
  Maximum scale of the model in column direction.
  Default value: 1.0
  Suggested values: ScaleCMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
  Restriction: ScaleCMax >= ScaleCMin
Deformable

MinScore (input_control) ........................................................ real \sim real
Minimum score of the instances of the model to be found.
Default value: 0.5
Suggested values: MinScore \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
Typical range of values: 0 \leq \text{MinScore} \leq 1
Minimum increment: 0.01
Recommended increment: 0.05

NumMatches (input_control) ............................................... integer \sim integer
Number of instances of the model to be found (or 0 for all matches).
Default value: 1
Suggested values: NumMatches \in \{0, 1, 2, 3, 4, 5, 10, 20\}

MaxOverlap (input_control) .............................................. real \sim real
Maximum overlap of the instances of the model to be found.
Default value: 1.0
Suggested values: MaxOverlap \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
Typical range of values: 0 \leq \text{MaxOverlap} \leq 1
Minimum increment: 0.01
Recommended increment: 0.05

NumLevels (input_control) .............................................. integer(-array) \sim integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if |\text{NumLevels}| = 2).
Default value: 0
List of values: NumLevels \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

Greediness (input_control) ................................................ real \sim real
“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default value: 0.9
Suggested values: Greediness \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
Typical range of values: 0 \leq \text{Greediness} \leq 1
Minimum increment: 0.01
Recommended increment: 0.05

GenParamName (input_control) ........................................... string-array \sim string
The general parameter names.
Default value: []
List of values: GenParamName \in \{\}, \text{"subpixel"}, \text{"angle_change_restriction"},
\text{"aniso_scale_change_restriction"}, \text{"angle_step"}, \text{"scale_r_step"}, \text{"scale_c_step"}, \text{"cov_pose_mode"}

GenParamValue (input_control) .......................................... integer-array \sim integer / real / string
Values of the general parameters.
Default value: []
List of values: GenParamValue \in \{\}, \text{"least_squares"}, \text{"least_squares_high"}, \text{"least_squares_very_high"},
\text{"standard_deviations"}, \text{"covariances"}

Pose (output_control) .................................................... pose(-array) \sim real / integer
Pose of the object.

CovPose (output_control) ............................................... real-array \sim real
6 standard deviations or 36 covariances of the pose parameters.

Score (output_control) .................................................. real-array \sim real
Score of the found instances of the model.

Result
If the parameters are valid, the operator \texttt{find_planar_calib_deformable_model} returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors
\texttt{create_planar_calib_deformable_model, read_deformable_model}
Find the best matches of a planar projective invariant deformable model in an image.

The operator `find_planar_uncalib_deformable_model` finds the best `NumMatches` instances of the perspectively distorted deformable model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_planar_uncalib_deformable_model` or `read_deformable_model`.

**Input parameters in detail**

**The image and its domain:** The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model`. A different origin set with `set_deformable_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with `set_system('border_shape_models','true')`, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., `dilation_circle`.

**Angle and Scale parameters:** The parameters `AngleStart`, `AngleExtent`, `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` are used to specify a basic range of up to an anisotropic transformation that is exhaustively searched on the top level of the image pyramid. The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations in which the model is exhaustively searched. `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` determine the range of possible anisotropic scales that are exhaustively searched in the image. A scale of 1 in both scale factors corresponds to the original size of the model.

The operator `find_planar_uncalib_deformable_model` may find objects outside this range, e.g., when the object is perspectively distorted. Hence, the range parameters are a kind of suggestion for the search algorithm. Starting from this, certain models in a wider range of transformations can be detected, depending on the used pyramid levels, but also on the model/image content. It is important to note that, e.g., small scale changes can be tolerated without the need to specify a scale range, leading to faster execution times.

Often, it is not necessary to use an anisotropic scaling to find the object on the top level of the pyramid. In these cases, `ScaleCMin` and `ScaleCMax` should be set to 1. The search is then performed with isotropic scaling only, which is much faster. If the object should be detected despite severe perspective distortions anisotropic scaling is required. Here, `ScaleRMin` and `ScaleRMax` specify the anisotropic scaling in row, and `ScaleCMin` and `ScaleCMax` in column direction.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Additionally, the operator `find_planar_uncalib_deformable_model` processes the parameters `angle_step`, `scale_r_step` and `scale_c_step` which can be set with the operator `create_planar_uncalib_deformable_model` or, as described below, with the generic parameters `GenParamName` and `GenParamValue`. In most cases, the values that can be determined automatically by `create_planar_uncalib_deformable_model` lead to good results.

The parameter `angle_step` determines the step size within the selected range of angles. `angle_step` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in
the image, and hence 'angle_step' should be chosen larger for smaller models. If AngleExtent is not an integer multiple of 'angle_step', 'angle_step' is modified accordingly. The parameters 'scale_r_step' and 'scale_c_step' determine the step size within the selected range of scales. Like 'angle_step', 'scale_r_step' and 'scale_c_step' should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of 'scale_r_step' and 'scale_c_step', 'scale_r_step' and 'scale_c_step' are modified accordingly.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0. In rare cases, NumMatches must be set to a higher value than the required number of matches. This is the case if, for instance, a small MinScore is set.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

GenParamName, GenParamValue: With the generic parameters GenParamName and GenParamValue it is possible to adjust parameters that typically do not have to be set by the user. By default the pose is extracted with high subpixel accuracy ('least_squares_very_high') through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. However, if no high accuracy is required by an application, the subpixel precise extraction can be reduced or switched off as it increases the processing time. Here, 'subpixel' must be passed in GenParamName and 'none', 'least_squares', 'least_squares_high' for GenParamValue. A further use of GenParamName and GenParamValue is to override the discretization steps of the search space 'angle_step', 'scale_r_step' and 'scale_c_step' that have been defined when the model was created in create_planar_uncalib_deformable_model. As described in create_planar_uncalib_deformable_model the deformable matching algorithm searches exhaustively a basic set of parameters that are specified with AngleStart,AngleExtent, ScaleRMin,ScaleRMax,ScaleCMin and ScaleCMax. However, to allow a detection even when the object is imaged under perspective distortion, an additional transformation is estimated. This additional transformation transforms the model from the original search range to a bigger perspective distorted one. By allowing perspective distortions, the risk of false positives is also increased. One possible use of the parameter GenParamName is to help discarding false positives that occur, if for instance a small score was specified in MinScore and the image contains significant clutter with similar shape as the model.

To restrict arbitrary perspective matches from occurring, the values 'angle_change_restriction' and 'aniso_scale_change_restriction' can be used in GenParamName. With 'angle_change_restriction' the maximal tolerated angular distortion can be restricted. As default value $\frac{\pi}{2}$ is set, which allows arbitrary distortion. By setting 'angle_change_restriction' to 0, no distortion is allowed at all. The set value should be within the interval $[0, \frac{\pi}{2}]$. This parameter tests, if the angle of 90 degree at the corners of the axis-aligned rectangle around the model points is changed by more than the corresponding GenParamValue for the found instance of the model. Note that this parameter helps to restrict both affine (a shear mapping) and perspective parts of the transformation. As an example, with 'angle_change_restriction' a square-like model can be prevented to match with a parallelogram or an arbitrary trapezium.

With the parameter 'aniso_scale_change_restriction' the ratio of anisotropic scaling can be restricted (the smaller scale factor divided by the bigger scale factor). The value of this parameter ranges from the default
value 0.0, where arbitrary distortion is allowed, to 1.0, where no distortion is allowed. One typical use for
this parameter is to restrict for instance a square-like model to deform to a rectangular model.

**NumLevels:** The number of pyramid levels used during the search is determined with `NumLevels`. If nec-
essary, the number of levels is clipped to the range given when the deformable model was created with
`create_planar_uncalib_deformable_model`. If `NumLevels` is set to 0, the number of pyramid
levels specified in `create_planar_uncalib_deformable_model` is used.

**Greediness:** The parameter `Greediness` determines how “greedily” the search should be carried out. If
`Greediness` = 0, a safe search heuristic is used, which finds the model if it is visible in the image and the
other parameters are set appropriately. However, the search will be relatively time consuming in this case. If
`Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare
cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved.
In almost all cases, the deformable model will be found for `Greediness` = 0.9.

### Output parameters in detail

**HomMat2D:** The projective transformation (homographies) that encode the position of the found in-
stances of the model are returned in `HomMat2D`. In case that multiple objects are found, the
different homographies are concatenated. A single homography can easily be extracted by
`tuple_select_range(HomMat2D,Index*9,(Index+1)*9-1, SelectedHomMat2D)`. The different detection re-
sults are sorted in decreasing order of `Score`. The row and column coordinates are the co-
ordinates of the origin of the deformable model in the search image, which can be found by
calling `projective_trans_pixel(HomMat2D,0,0,Row,Column)`. By default, the origin is the center
of gravity of the domain (region) of the image that was used to create the deformable model
with `create_planar_uncalib_deformable_model`. A different origin can be set with
`set_deformable_model_origin`. For visualization purposes, the model contours that are extracted
by `get_deformable_model_contours` can be projected to the found location given `HomMat2D` with
`projective_trans_contour_xld`.

**Score:** Additionally, the score of each found instance is returned in `Score`. The score is a number between 0 and
1, which is an approximate measure of how much of the model is visible in the image. If, for example, half
of the model is occluded, the score cannot exceed 0.5.

---

### Parameters

- **Image** *(input_object) (multichannel-)image ~ object : byte / uint2*
  Input image in which the model should be found.

- **ModelID** *(input_control) deformable_model ~ handle*
  Handle of the model.

- **AngleStart** *(input_control) angle.rad ~ real*
  Smallest rotation of the model.
  **Default value:** -0.39
  **Suggested values:** `AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}`

- **AngleExtent** *(input_control) angle.rad ~ real*
  Extent of the rotation angles.
  **Default value:** 0.78
  **Suggested values:** `AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39, 0.0}`
  **Restriction:** `AngleExtent ≥ 0`

- **ScaleRMin** *(input_control) number ~ real*
  Minimum scale of the model in row direction.
  **Default value:** 1.0
  **Suggested values:** `ScaleRMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}`
  **Restriction:** `ScaleRMin > 0`

- **ScaleRMax** *(input_control) number ~ real*
  Maximum scale of the model in row direction.
  **Default value:** 1.0
  **Suggested values:** `ScaleRMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}`
  **Restriction:** `ScaleRMax ≥ ScaleRMin`
18.3. DEFORMABLE

- **ScaleCMin** (input_control) ................................................................. number  \(\rightarrow\) real
  Minimum scale of the model in column direction.
  Default value: 1.0
  Suggested values: \(\text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Restriction: \(\text{ScaleCMin} > 0\)

- **ScaleCMax** (input_control) ................................................................. number  \(\rightarrow\) real
  Maximum scale of the model in column direction.
  Default value: 1.0
  Suggested values: \(\text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)
  Restriction: \(\text{ScaleCMax} \geq \text{ScaleCMin}\)

- **MinScore** (input_control) ................................................................. real  \(\rightarrow\) real
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumMatches** (input_control) ............................................................. integer  \(\rightarrow\) integer
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)

- **MaxOverlap** (input_control) ............................................................. real  \(\rightarrow\) real
  Maximum overlap of the instances of the model to be found.
  Default value: 1.0
  Suggested values: \(\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MaxOverlap} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **NumLevels** (input_control) ............................................................ integer(-array)  \(\rightarrow\) integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).
  Default value: 0
  List of values: \(\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}\)

- **Greediness** (input_control) ............................................................ real  \(\rightarrow\) real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  Default value: 0.9
  Suggested values: \(\text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{Greediness} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05

- **GenParamName** (input_control) ......................................................... string-array  \(\rightarrow\) string
  The general parameter names.
  Default value: \[
  \]  
  List of values: \(\text{GenParamName} \in \{["", \text{subpixel"}, \text{angle_change_restriction"}, \text{aniso_scale_change_restriction"}, \text{angle_step"}, \text{scale_r_step"}, \text{scale_c_step"}\}\}

- **GenParamValue** (input_control) ....................................................... integer-array  \(\rightarrow\) integer / real / string
  Values of the general parameters.
  Default value: \[
  \]  
  List of values: \(\text{GenParamValue} \in \{["", \text{none"}, \text{least_squares"}, \text{least_squares_high"}, \text{least_squaresVery_high"}\}\}

- **HomMat2D** (output_control) ......................................................... hom_mat2d(-array)  \(\rightarrow\) real
  Homographies between model and found instances.

- **Score** (output_control) ................................................................. real-array  \(\rightarrow\) real
  Score of the found instances of the model.

---

**Result**
If the parameters are valid, the operator **find_planar_uncalib_deformable_model** returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

**Execution Information**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

get_deformable_model_contours ( : ModelContours : ModelID, Level : )

Return the contour representation of a deformable model.

The operator get_deformable_model_contours returns a representation of the deformable model ModelID as XLD contours in ModelContours. The parameter Level determines for which pyramid level of the model the contour representation should be returned. The contours can be used, for example, to visualize the found instances of the model in an image.

In case that the model was generated by create_planar_calib_deformable_model_xld, the contours by default are returned in the world coordinate system in metric units. Here, the contours must be transformed by the returned pose for visualizing a match.

In all other cases, the contours of the model by default are returned in the image coordinate system in pixel units. In the calibrated case this system corresponds to the rectified image coordinate system. The rectified image coordinate system is the coordinate system of an image one would obtain by change_radial_distortion_image when using the rectified camera parameters. The rectified camera parameters can be queried by get_deformable_model_params. It should be noted that the position of ModelContours is normalized such that the reference point of the model (see set_deformable_model_origin) lies at the pixel position (0,0). Hence, the contours simply need to be transformed by the found homography in the image.

The default behavior for the calibrated case can be changed with the generic parameter 'get_deformable_model_contours_coord_system' of the operator set_deformable_model_param.

Parameters

¬ ModelContours (output_object) ........................................... xld_cont-array  object Contour representation of the deformable model.
¬ ModelID (input_control) ................................................. deformable_model  handle Handle of the model.
¬ Level (input_control) ................................................... integer  integer Pyramid level for which the contour representation should be returned.
  Default value: 1
  Suggested values: Level ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
  Restriction: Level >= 1

Result

If the handle of the model is valid, the operator get_deformable_model_contours returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
Return the origin (reference point) of a deformable model.

The operator `get_deformable_model_origin` returns the origin (reference point) of the deformable model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

### Parameters

- **ModelID** (input_control) .........................., deformable_model ↦ `handle`
  Handle of the model.
- **Row** (output_control) ............................., point.y ↦ `real`
  Row coordinate of the origin of the deformable model.
- **Column** (output_control) ..........................., point.x ↦ `real`
  Column coordinate of the origin of the deformable model.

### Result

If the handle of the model is valid, the operator `get_deformable_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```c
get_deformable_model_params ( : : ModelID,  
  GenParamName : GenParamValue )
```

Return the parameters of a deformable model.
The operator `get_deformable_model_params` allows to query parameters of the deformable model. The names of the desired parameters are passed in the generic parameter `GenParamName`, the corresponding values are returned in `GenParamValue`.

The following parameters can be queried:

- `'cam_param'`: Internal parameters of the camera that is used for the calibrated case.
- `'cam_param_rect'`: Rectified internal parameters of the camera that is used for the calibrated case.
- `'reference_pose'`: Reference position and orientation of the calibrated deformable model. The returned pose describes the model plane that the user provided.
- `'model_pose'`: Reference position and orientation of the deformable model. The returned pose describes the pose of the internally used 3D metric model that was used for model generation.
- `'angle_start'`: The smallest rotation angle of the model.
- `'angle_extent'`: The extent of the rotation angle of the model.
- `'angle_step'`: The angle step length of the model.
- `'scale_r_min'`: The minimum scale of the pattern in row direction.
- `'scale_r_max'`: The maximum scale of the pattern in row direction.
- `'scale_r_step'`: The scale step of the pattern in row direction.
- `'scale_c_min'`: The minimum scale of the pattern in column direction.
- `'scale_c_max'`: The maximum scale of the pattern in column direction.
- `'scale_c_step'`: The scale step of the pattern in column direction.
- `'num_levels'`: User-specified number of pyramid levels.
- `'optimization'`: Kind of optimization by reducing the number of model points.
- `'min_size'`: Minimum size of the deformable model edge.
- `'min_contrast'`: Minimum contrast of the objects in the search images.
- `'metric'`: Match metric.
- `'model_row'`: Row coordinate of origin in the radial undistorted model image.
- `'model_col'`: Column coordinate of origin in the radial undistorted model image.
- `'model_type'`: The type of the model: 'planar_uncalib', 'planar_calib' or 'local'.
- `'created_from_xld'`: Was the model created from XLD or from an image: 'created_from_xld' or 'created_from_image'.
- `'get_deformable_model_contours_coord_system'`: Coordinate system ('image' or 'world') in which contours are returned when calling the operator `get_deformable_model_contours`.

A detailed description of the parameters can be looked up with the operator `create_planar_uncalib_deformable_model` and `create_planar_calib_deformable_model` or with the operator `get_deformable_model_contours`.

Note that although the parameter `Contrast` can be determined automatically during the model creation, its value cannot be queried using `get_deformable_model_params`. Instead, the operator `determine_deformable_model_params` should be used to retrieve its value.

It is possible to query the values of several parameters with a single operator call by passing a tuple containing the names of all desired parameters to `GenParamName`. As a result a tuple of the same length with the corresponding values is returned in `GenParamValue`. Note that this is solely possible for parameters that return only a single value.

---

**Parameters**

- `ModelID` (input_control) .......................................................... deformable_model ↦ handle
  Handle of the model.
- `GenParamName` (input_control) ................................................. attribute.name(-array) ↦ string
  Names of the generic parameters that are to be queried for the deformable model.

**Default value:** 'angle_start'

**List of values:** `GenParamName` ∈ {'cam_param', 'cam_param_rect', 'angle_start', 'angle_extent', 'angle_step', 'scale_r_min', 'scale_r_max', 'scale_r_step', 'scale_c_min', 'scale_c_max', 'scale_c_step', 'optimization', 'metric', 'min_contrast', 'num_levels', 'min_size', 'reference_pose', 'model_pose', 'model_row', 'model_col', 'model_type', 'created_from_xld', 'get_deformable_model_contours_coord_system'}
18.3. DEFORMABLE

Matching

HALCON 20.11.0.0
**serialize_deformable_model** ( : : ModelID : SerializedItemHandle )

Serialize a deformable model.

serialize_deformable_model serializes the data of a deformable model (see **fwrite_serialized_item** for an introduction of the basic principle of serialization). The same data that is written in a file by **write_deformable_model** is converted to a serialized item. The deformable model is defined by the handle ModelID. The serialized deformable model is returned by the handle SerializedItemHandle and can be deserialized by **deserialize_deformable_model**.

**Parameters**

- ModelID (input_control) ................. deformable_model ↵ handle
  Handle of a model to be saved.
- SerializedItemHandle (output_control) .......... serialized_item ↵ handle
  Handle of the serialized item.

**Result**

If the parameters are valid, the operator serialize_deformable_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

**Possible Successors**

**set_deformable_model_origin** ( : : ModelID, Row, Column : )

Set the origin (reference point) of a deformable model.

The operator set_deformable_model_origin sets the origin (reference point) of the deformable model ModelID to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the deformable model with **create_planar_uncalib_deformable_model**. Hence, an origin of (0,0) means that the center of gravity of the domain of the deformable image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity. If a deformable model was created by **create_planar_calib_deformable_model** the 3D pose of the origin changes by the respective translation. Hence, further calls of **find_planar_calib_deformable_model** will include the pose offset. If a deformable model was created by **create_planar_calib_deformable_model_xid** the 3D pose of the origin changes directly by the offset. This means that the offsets are interpreted in world coordinates. In this case, the row coordinate corresponds to the y world coordinate (from top to down) and the column coordinate corresponds to the x world coordinate (from left to right).

**Parameters**

- ModelID (input_control) ......................... deformable_model ↵ handle
  Handle of the model.
- Row (input_control) .......................... point.y ↵ real
  Row coordinate of the origin of the deformable model.
- Column (input_control) ......................... point.x ↵ real
  Column coordinate of the origin of the deformable model.
18.3. DEFORMABLE

Result

If the handle of the model is valid, the operator `set_deformable_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```
set_deformable_model_param ( : : ModelID, GenParamName, GenParamValue : )
```

Set selected parameters of the deformable model.

The operator `set_deformable_model_param` sets the selected parameters `GenParamName` in the deformable model `ModelID`. The following parameters can be modified:

'`min_contrast`

Sets the minimum contrast of the object in the search images for the deformable model `ModelID`. Thereby, the value of 'min_contrast' that was originally set, e.g., with `create_planar_uncalib_deformable_model`, is overwritten for the deformable model `ModelID`. Note that if the deformable model `ModelID` was read from file and if this file should be changed as well, the deformable model `ModelID` must again be written to file after the execution of the operator `set_deformable_model_param`.

'get_deformable_model_contours_coord_system`

Sets the coordinate system in which the contours are returned when calling the operator `get_deformable_model_contours`. If 'world' is passed, the contours are returned in the world coordinate system in metric units. Note that this is only possible for the calibrated case. If 'image' is passed, the contours are returned in the image coordinate system in pixel units. In the calibrated case this system corresponds to the rectified image coordinate system. The rectified image coordinate system is the coordinate system of an image one would obtain by `change_radial_distortion_image` when using the rectified camera parameters. The rectified camera parameters can be queried by `get_deformable_model_params`. If the model was created by `create_planar_calib_deformable_model_xld` the value of 'get_deformable_model_contours_coord_system' is 'world' by default. In all other cases it is 'image' by default.
Parameters

- **ModelID** (input_control) – Handle of the model.
- **GenParamName** (input_control) – Parameter names. List of values: `GenParamName ∈ {‘min_contrast’, ‘get_deformable_model_contours_coord_system’}`
- **GenParamValue** (input_control) – Parameter values. Suggested values: `GenParamValue ∈ {5, 6, 7, 8, 9, 10, ’image’, ’world’}`

If the parameters are valid, the operator `set_deformable_model_param` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Matching

```
set_local_deformable_model_metric ( Image,
    VectorField : ModelID, Metric : )
```

Set the metric of a local deformable model that was created from XLD contours.

The parameter **Metric** then determines the conditions under which the model is recognized later in the search image. If **Metric** = ‘use_polarity’, the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If **Metric** = ‘ignore_global_polarity’, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_local_deformable_model` will increase slightly in this case.
It must be ensured that the object contours in the `Image` have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the `Image` and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in `Image`, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter `Metric` to `'ignore_local_polarity'`. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image is provided in `VectorField`, which is of the semantic type `vector_field_absolute`. If the matching result is correct, the value of the parameter `Metric` can be changed, e.g., to `'use_polarity'`. This leads to a faster and more robust recognition in the following images.

```plaintext
Attention

set_local_deformable_model_metric can only be used with deformable models that were created from XLD contours.
```

### Parameters

- **Image** (input_object) singlechannelimage object : byte / uint2
  Input image used for the determination of the polarity.
- **VectorField** (input_object) singlechannelimage object : vector_field
  Vector field of the local deformation.
- **ModelID** (input_control) deformable_model handle
  Handle of the model.
- **Metric** (input_control) string
  Match metric.
  Default value: `'use_polarity'`
  List of values: `Metric ∈ { 'use_polarity', 'ignore_global_polarity' }`

### Result

If the parameters are valid, the operator `set_local_deformable_model_metric` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Module

`set_planar_calib_deformable_model_metric(Image : : ModelID, Pose, Metric : )`

Set the metric of a planar calibrated deformable model that was created from XLD contours.
set_planar_calib_deformable_model_metric changes the value of the parameter \texttt{Metric} that was selected during the creation of the deformable model \texttt{ModelID} from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative \texttt{Image}. For this, the model contours are mapped to the respective position where the object appears in the \texttt{Image} using \texttt{Pose}, which can be obtained by a previous call to \texttt{find_planar_calib_deformable_model}.

The parameter \texttt{Metric} then determines the conditions under which the model is recognized later in the search image. If \texttt{Metric} = 'use_polarity', the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If \texttt{Metric} = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of \texttt{find_planar_calib_deformable_model} will increase slightly in this case.

It must be ensured that the object contours in the \texttt{Image} have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the \texttt{Image} and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in \texttt{Image}, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter \texttt{Metric} to 'ignore_local_polarity'. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image \texttt{Pose} can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter \texttt{Metric} can be changed, e.g., to 'use_polarity'. This leads to a faster and more robust recognition in the following images.

---

\textbf{Attention}

\texttt{set_planar_calib_deformable_model_metric} can only be used with deformable models that were created from XLD contours.

---

\textbf{Parameters}

- \textbf{Image} (input\_object) \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \texttt{singlechannelimage} $\sim$ \texttt{object} : byte / uint2
  
  Input image used for the determination of the polarity.

- \textbf{ModelID} (input\_control) \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \texttt{deformable\_model} $\sim$ \texttt{handle}
  
  Handle of the model.

- \textbf{Pose} (input\_control) \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \texttt{pose} $\sim$ \texttt{real / integer}
  
  Pose of the model in the image.

  \textbf{Number of elements:} 7

- \textbf{Metric} (input\_control) \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \texttt{string} $\sim$ \texttt{string}
  
  Match metric.

  \textbf{Default value:} 'use\_polarity'

  \textbf{List of values:} \texttt{Metric} \in \{ 'use\_polarity', 'ignore\_global\_polarity' \}

---

\textbf{Result}

If the parameters are valid, the operator \texttt{set_planar_calib_deformable_model_metric} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

| set_planar_uncalib_deformable_model_metric ( Image : : ModelID, HomMat2D, Metric : ) |

Set the metric of a planar uncalibrated deformable model that was created from XLD contours.

set_planar_uncalib_deformable_model_metric changes the value of the parameter Metric that was selected during the creation of the deformable model ModelID from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative Image. For this, the model contours are mapped to the respective position where the object appears in the Image using HomMat2D, which can be obtained by a previous call to find_planar_uncalib_deformable_model.

The parameter Metric then determines the conditions under which the model is recognized later in the search image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_planar_uncalib_deformable_model will increase slightly in this case.

It must be ensured that the object contours in the Image have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the Image and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in Image, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter Metric to 'ignore_local_polarity'. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image (HomMat2D) can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter Metric can be changed, e.g., to 'use_polarity'. This leads to a faster and more robust recognition in the following images.

Attention

set_planar_uncalib_deformable_model_metric can only be used with deformable models that were created from XLD contours.

Parameters

- **Image** (input_object) ........................................... singlechannelimage ～ object : byte / uint2
  Input image used for the determination of the polarity.
- **ModelID** (input_control) ................................... deformable_model ～ handle
  Handle of the model.
- **HomMat2D** (input_control) .................................. hom_mat2d ～ real
  Transformation matrix.
- **Metric** (input_control) ..................................... string ～ string
  Match metric.

  Default value: 'use_polarity'
  List of values: Metric ∈ {'use_polarity', 'ignore_global_polarity'}
If the parameters are valid, the operator `set_planar_uncalib_deformable_model_metric` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

- `create_planar_calib_deformable_model`
- `create_local_deformable_model`

**Matching**
18.4 Descriptor-Based

**clear_descriptor_model** ( : : ModelID ;

Free the memory of a descriptor model.

The operator `clear_descriptor_model` frees the memory of a descriptor model that was created by `create_calib_descriptor_model` or `create_uncalib_descriptor_model`. After calling `clear_descriptor_model`, the model can no longer be used. The handle `ModelID` becomes invalid.

---

**Parameters**

- `ModelID` (input_control) : descriptor_model(-array) ~ handle
  Handle of the descriptor model.

---

**Result**

If the handle of the model is valid, the operator `clear_descriptor_model` returns the value 2 (H.MSG_TRUE). If necessary an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**Module**

Matching

**create_calib_descriptor_model** ( Template : : CamParam,
ReferencePose, DetectorType, DetectorParamName, DetectorParamValue,
DescriptorParamName, DescriptorParamValue, Seed : : ModelID )

Create a descriptor model for calibrated perspective matching.

The operator `create_calib_descriptor_model` prepares a descriptor model, which is used for calibrated descriptor-based matching, from a template image that is passed in `Template` (usually the domain of the image is reduced to an ROI showing only the object of interest). Note that the part of the object that is visible in the `Template` image needs to be planar.

The internal camera parameters `CamParam` and the `ReferencePose`, which describes the 3D position and orientation of the object plane shown in `Template`, are used to internally calculate a model coordinate system. The origin of this model coordinate system is obtained by projecting the center of gravity of an internally rectified version of the template image onto the object plane. The axes of the model coordinate system are built such that they are parallel to the axes of Reference Pose. To obtain a descriptor model from the template image, the points extracted by the detector in the internally rectified template image are projected onto the object plane as well. Their coordinates in the model coordinate system are stored as world coordinates in the model. This model then can be used for the pose estimation of a searched object as described with `find_calib_descriptor_model`.

A descriptor model created by the use of `create_calib_descriptor_model` can also be used in `find_uncalib_descriptor_model` to determine a homography. In contrast, it is not possible to use a model created by `create_uncalib_descriptor_model` in `find_calib_descriptor_model`.

The descriptor model describes a set of points of interest. It stores their locations and discriminative descriptions of their local gray value neighborhood. The interest point extraction is parametrized by `DetectorType`,.
DetectorParamName and DetectorParamValue. The respective descriptor around the interest points is parametrized by DescriptorParamName and DescriptorParamValue. The parameter Seed seeds the random number generator, which is used during the construction of the descriptor implemented with randomized ferns. The returned ModelID is a reference to the generated descriptor model. For further explanation on the descriptor model and its parameter we refer to the description of create_uncalib_descriptor_model.

The parameters and the location of the final descriptor points can be determined with get_descriptor_model_params and get_descriptor_model_points.

create_calib_descriptor_model stores the detector type, detector parameters and descriptor parameters, which are used in every succeeding call of find_calib_descriptor_model or find_uncalib_descriptor_model. The reference point (origin) of the model is the center of gravity of the template’s ROI. Its coordinates can be changed by set_descriptor_model_origin.

Parameters

- **Template** (input_object) singlechannelimage ~ object : byte / uint2
  Input image whose domain will be used to create the model.

- **CamParam** (input_control) campar ~ real / integer / string
  The parameters of the internal orientation of the camera.

- **ReferencePose** (input_control) pose ~ real / integer
  The reference pose of the object in the reference image.

- **DetectorType** (input_control) string
  The type of the detector.
  Default value: 'lepetit'
  List of values: DetectorType ∈ {'lepetit', 'harris', 'harris_binomial'}

- **DetectorParamName** (input_control) attribute.name-array ~ string
  The detector’s parameter names.
  Default value: []
  List of values: DetectorParamName ∈ {'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold'}

- **DetectorParamValue** (input_control) attribute.value-array ~ integer / real / string
  Values of the detector’s parameters.
  Default value: []
  Suggested values: DetectorParamValue ∈ {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off'}

- **DescriptorParamName** (input_control) attribute.name-array ~ string
  The descriptor’s parameter names.
  Default value: []
  List of values: DescriptorParamName ∈ {'depth', 'max_rot', 'max_scale', 'min_rot', 'min_scale', 'number_ferns', 'patch_size', 'tilt'}

- **DescriptorParamValue** (input_control) attribute.value-array ~ integer / real / string
  Values of the descriptor’s parameters.
  Default value: []
  Suggested values: DescriptorParamValue ∈ {0.5, 1.4, 11, 21, 30, -180, 180, 'on', 'off'}

- **Seed** (input_control) integer
  The seed for the random number generator.
  Default value: 42

- **ModelID** (output_control) descriptor_model ~ handle
  The handle to the descriptor model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

create_uncalib_descriptor_model ( Template : : DetectorType, DetectorParamName, DetectorParamValue, DescriptorParamName, DescriptorParamValue, Seed : ModelID )

Prepare a descriptor model for interest point matching.

The operator create_uncalib_descriptor_model prepares a descriptor model of an image region, which is passed in the image Template, that can be used for descriptor-based matching. By a subsequent call of find_uncalib_descriptor_model a projective 2D transformation (homography) from Template to a search image can be obtained. The center of gravity of the domain region in Template is used as an origin of the model. In contrast to create_calib_descriptor_model, no calibrated camera is needed and hence the result of a subsequent matching is a 2D projection. Note that the part of the object that is visible in the Template image needs to be planar.

The descriptor model describes a set of points of interest. It stores their locations and discriminative descriptions of their local gray value neighborhood. The interest point extraction is parametrized by DetectorType, DetectorParamName, and DetectorParamValue. The respective descriptor around the interest points is parametrized by DescriptorParamName and DescriptorParamValue. The parameter Seed seeds the random number generator, which is used during the construction of the descriptor implemented with randomized ferns. The returned ModelID is a reference to the generated descriptor model. This model can be used for an efficient detection of instances of the learned template with find_uncalib_descriptor_model, allowing perspective transformation between model and search image. As descriptor-based matching relies on the existence of stable and discriminative points of interest, the object to be detected must be textured, but not in a repetitive way.

Detector parameters

As mentioned, the detector is used for the extraction of stable interest points within the image. By the parameter DetectorType, it is possible to select the interest point operator to be used. Currently, points_lepetit, points_harris, and its binomial approximation points_harris_binomial are supported (’lepetit’, ’harris’, ’harris_binomial’). In case of templates or search images with a low contrast, one of the Harris point operators should be used. Depending on the selected DetectorType, appropriate parameter names and values can be set in DetectorParamName and DetectorParamValue.

Possible parameter names for DetectorParamName and corresponding default values are:

’lepetit’: [’radius’, ’check_neighbor’, ’min_check_neighbor_diff’, ’min_score’, ’subpix’]
[3, 1, 15, 30, ’interpolation’]

’harris’: [’sigma_grad’, ’sigma_smooth’, ’alpha’, ’threshold’]
[0.7, 2.0, 0.08, 1000]

[5, 15, 0.08, 1000, ’on’]
Further details on the meaning of those parameters can be found in the descriptions of points_harris, points_harris_binomial and points_lepetit, respectively. If an empty tuple is passed or a parameter is not provided in DetectorParamName, the above mentioned default values are taken.

While adjusting the operator parameters it should be aimed that a set of 50 to 450 feature points is extracted (depending on the texture and size of Template), which are uniformly distributed over the template’s ROI. Therefore, it is recommended to run the point operator of choice in advance and visualize the results by gen_cross_contour_xld. In most cases it is sufficient to use the default setting.

**Descriptor parameters**

A point descriptor is a classifier, which builds characteristic descriptions of the gray-value neighborhood for interest points. Currently the descriptor is implemented with the so-called randomized ferns, which learns the polarity of the gray-value differences of pairs of pixels certain at random locations in the surrounding area of the interest point. The descriptor is later used in find_uncalib_descriptor_model to classify interest points in the search image, or in other words: to identify (match) potential model points in the search image.

The descriptor needs to store only the projectively stable interest points (which will appear in many projective views of the template). To assess the stability of the interest points, a simulation is performed: Template undergoes many affine transformations and points that can be extracted in most of the views are considered stable. The affine transformations are a good approximation of the projective transformations within a local neighborhood of the interest points.

The following descriptor parameters can be set with DescriptorParamName and DescriptorParamValue:

**Descriptor size parameters:**

'field': depth of a classification fern. A deeper randomized fern can better discriminate interest points. However, the memory requirement for the fern grows by a factor 2 to the power of 'field'.

Typical values are \([5 \ldots 11]\), default value is 11.

'field': number of fern structures used. Using more ferns increases the recognition robustness, however it also increases the runtime of the matching. If the memory needed for the descriptor should be small, many ferns with only a small depth should be used (e.g., 'number_ferns'=150, 'field'=5). If detection speed is more important, fewer ferns of larger depth should be used (e.g., 'number_ferns'=10, 'field'=11).

Typical values are \([1 \ldots 150]\), default value is 30.

'field': side length of a quadratic neighborhood describing a point of interest. Too large values of this parameter can influence the run time.

Typical values are \([15 \ldots 33]\), default value is 17.

Summing up, the parameters 'field', 'number_ferns' and 'field' allow a transparent control over detection robustness, speed and memory consumption.

**Simulation parameters:**

'field': switches on or off the projective transformations during the simulation phase. When switched on, the robustness of the model is improved and objects with bigger tilts can be found. When switched off, training time can be significantly reduced and the model is still able to recognize projectively invariant objects.

Possible values are ['on', 'off'], default value is 'on'.

'field': minimal angle of rotation around the normal vector of Template.

Typical values are \([-180 \ldots 0]\), default value is -180.

'field': maximal angle of rotation around the normal vector of Template.

Typical values are \([0 \ldots 180]\), default value is 180.

'field': minimal scale of Template.

Typical values are \([0.1 \ldots 1.0]\), default value is 0.5.

'field': maximal scale of Template.

Typical values are \([1.0 \ldots 3.5]\), default value is 1.4.

The parameters 'field', 'max_rot', 'min_scale', and 'max_scale' allow to manually set which affine transformed views of the template are used to train the descriptor. Setting these parameters is useful to reduce training time especially in combination with the parameter 'tilt'. Be aware that these parameters have direct influence on the results of find_uncalib_descriptor_model and therefore have to be set carefully. If, for example, the range of rotation is restricted from 'min_rot' = -10 to 'max_rot' = 10 it is not possible to find views of Template rotated...
by an angle outside that scope. A limited training range requires less ferns / ferns' depths to find Template. In such a case the number and depth of the ferns can be further reduced, which optimizes the model.

Remarks

Please note that depending on your hardware, the processing time for training the randomized ferns can vary between several seconds to some minutes. Therefore, a once trained model can be saved and loaded with write_descriptor_model and read_descriptor_model.

The parameters and the location of the final descriptor points can be determined with get_descriptor_model_params and get_descriptor_model_points.

create_uncalib_descriptor_model stores the detector type, detector parameters, and descriptor parameters, which are used in every succeeding call of find_uncalib_descriptor_model. The reference point (origin) of the model is the center of gravity of the template’s ROI. Its coordinates can be changed by set_descriptor_model_origin.

Parameters

- **Template** (input_object) .......................... singlechannelimage  \(\sim\) object : byte / uint2
  Input image whose domain will be used to create the model.

- **DetectorType** (input_control) .......................... string  \(\sim\) string
  The type of the detector.
  **Default value:** ‘lepetit’
  **List of values:** DetectorType \(\in\) {'lepetit', 'harris', 'harris_binomial'}

- **DetectorParamName** (input_control) .......................... attribute.name-array  \(\sim\) string
  The detector’s parameter names.
  **Default value:** []
  **List of values:** DetectorParamName \(\in\) {'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold'}

- **DetectorParamValue** (input_control) .......................... attribute.value-array  \(\sim\) integer / real / string
  Values of the detector’s parameters.
  **Default value:** []
  **Suggested values:** DetectorParamValue \(\in\) {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off', 'none', 'interpolation'}

- **DescriptorParamName** (input_control) .......................... attribute.name-array  \(\sim\) string
  The descriptor’s parameter names.
  **Default value:** []
  **List of values:** DescriptorParamName \(\in\) {'depth', 'max_rot', 'max_scale', 'min_rot', 'min_scale', 'number_ferns', 'patch_size', 'tilt'}

- **DescriptorParamValue** (input_control) .......................... attribute.value-array  \(\sim\) integer / real / string
  Values of the descriptor’s parameters.
  **Default value:** []
  **Suggested values:** DescriptorParamValue \(\in\) {0.5, 1, 1.4, 11, 21, 30, -180, 180, 'on', 'off'}

- **Seed** (input_control) .......................... integer  \(\sim\) integer
  The seed for the random number generator.
  **Default value:** 42

- **ModelID** (output_control) .......................... descriptor_model  \(\sim\) handle
  The handle to the descriptor model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module
Matching

deserialize_descriptor_model (:
  SerializedItemHandle : ModelID)

Deserialize a descriptor model.

deserialize_descriptor_model deserializes a descriptor model, that was serialized by serialize_descriptor_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized descriptor model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created descriptor model with the handle ModelID.

Parameters

• SerializedItemHandle (input_control) ............................................. serialized_item \rightarrow handle
Handle of the serialized item.

• ModelID (output_control) .................................................... descriptor_model \rightarrow handle
Handle of the model.

Result

If the parameters are valid, the operator deserialize_descriptor_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module
Matching

find_calib_descriptor_model ( Image : ModelID,
  DetectorParamName, DetectorParamValue, DescriptorParamName,
  DescriptorParamValue, MinScore, NumMatches, CamParam,
  ScoreType : Pose, Score )

Find the best matches of a calibrated descriptor model in an image and return their 3D pose.
The operator `find_calib_descriptor_model` finds the best `NumMatches` matches of the descriptor model `ModelID` in `Image`. The descriptor model must have been created previously by calling `create_calib_descriptor_model` or `read_descriptor_model`.

The operator returns the 3D Pose (in camera coordinate system) of the template object found in the search `Image`. As two different cameras can be used for the model generation and the online search, the camera parameters of the camera used to create `Image` have to be set in `CamParam`.

The detection process is the same as for `find_uncalib_descriptor_model`. The setting of `DetectorParamName`, `DetectorParamValue`, `DescriptorParamName`, `DescriptorParamValue`, `MinScore`, `NumMatches` and `ScoreType` are explained with `find_uncalib_descriptor_model`. After the object was detected, and using the world (from reference plane) coordinates of the matched model points (explained with `create_calib_descriptor_model`), the pose of the object is computed similarly to applying `vector_to_pose` operator.

The point correspondences for each object can be queried with `get_descriptor_model_points`.

---

**Attention**

Note that the domain of the search image should contain the whole object to be searched for because interest points are only extracted inside the domain of the search image. This means that if the domain does not contain the full object to be searched for, the resulting `Score` will decrease. Note also that matches may be found even if the reference point (origin) of the model lies outside of the domain of the search image. Both is in contrast to shape-based matching, where the domain of the search image defines the search space for the reference point of the model.

---

**Parameters**

- **Image** (input_object) .......................... singlechannelimage  \(\sim\) object : byte / uint2
  Input image where the model should be found.

- **ModelID** (input_control) .......................... descriptor_model  \(\sim\) handle
  The handle to the descriptor model.

- **DetectorParamName** (input_control) .................. attribute.name-array  \(\sim\) string
  The detector’s parameter names.
  Default value: []

  List of values: `DetectorParamName` \(\in\) {’alpha’, ’check_neighbor’, ’mask_size_grd’,
  ’mask_size_smooth’, ’min_check_neighbor_diff’, ’min_score’, ’radius’, ’sigma_grad’, ’sigma_smooth’,
  ’subpix’, ’threshold’}

- **DetectorParamValue** (input_control) .................. attribute.value-array  \(\sim\) integer / real / string
  Values of the detector’s parameters.
  Default value: []

  Suggested values: `DetectorParamValue` \(\in\) {0.08, 1, 1.2, 3, 15, 30, 1000, ’on’, ’off’}

- **DescriptorParamName** (input_control) .................. attribute.name-array  \(\sim\) string
  The descriptor’s parameter names.
  Default value: []

  List of values: `DescriptorParamName` \(\in\) {’min_score_descr’, ’guided_matching’}

- **DescriptorParamValue** (input_control) .................. attribute.value-array  \(\sim\) real / integer / string
  Values of the descriptor’s parameters.
  Default value: []

  Suggested values: `DescriptorParamValue` \(\in\) {0.0, 0.001, 0.005, 0.01, ’on’, ’off’}

- **MinScore** (input_control) .......................... real(-array)  \(\sim\) real
  Minimum score of the instances of the models to be found.
  Default value: 0.2

  Suggested values: `MinScore` \(\in\) {0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}

  Typical range of values: \(0 \leq \text{MinScore} \leq 1\)

- **NumMatches** (input_control) .......................... integer  \(\sim\) integer
  Maximal number of found instances.
  Default value: 1

  Suggested values: `NumMatches` \(\in\) {1, 2, 3, 4}

  Restriction: `NumMatches` \(\geq\) 1

- **CamParam** (input_control) .......................... campar  \(\sim\) real / integer / string
  Camera parameter (inner orientation) obtained from camera calibration.
> **ScoreType** (input control) ................................. string(-array)  \sim string
Score type to be evaluated in **Score**.
Default value: ‘num_points’
List of values: ScoreType \in \{‘num_points’, ‘inlier_ratio’\}

> **Pose** (output_control) ................................. pose(-array)  \sim real / integer
3D pose of the object.

> **Score** (output_control) ................................. number(-array)  \sim real / integer
Score of the found instances according to the ScoreType input.

---

**Example**

* Perform camera calibration (with standard calibration plate)
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* World coordinate system is defined by calibration plate in first image
get_calib_data (CalibDataID, 'calib_obj_pose', [0,0], 'pose', 
    ObjInCameraPose)
* Compensate thickness of plate
set_origin_pose(ObjInCameraPose, 0, 0, 0.0006, WorldPose)

* Create descriptor model:
create_calib_descriptor_model (Image,CamParam,WorldPose, \n    'harris',[],[],[],[],42,ModelID)

get_descriptor_model_params (ModelID,DetectorType, \n    DetectorParamName,DetectorParamValue, \n    DescriptorParamName,DescriptorParamValue)
write_descriptor_model (ModelID,'simple_example.dsm')

read_descriptor_model ('simple_example.dsm',ModelID)
find_calib_descriptor_model (SearchImage,ModelID,[],[],[],0.2,1, \n    CamParam,['num_points','inlier_ratio'], \n    Pose,Score)

---

**Module**

**find_uncalib_descriptor_model** ( Image : : ModelID,
    DetectorParamName, DetectorParamValue, DescriptorParamName,
    DescriptorParamValue, MinScore, NumMatches, ScoreType : HomMat2D,
    Score )

Find the best matches of a descriptor model in an image.
The operator **find_uncalib_descriptor_model** finds the best matches of a descriptor model **ModelID** in **Image**. The descriptor model must have been created previously by
calling `create_uncalib_descriptor_model`, `create_calib_descriptor_model` or `read_descriptor_model`.

A match is only accepted if its score exceeds the value of `MinScore`. This criterion is based on the 'inlier_ratio' score that is described in details below. The main result of the operator `find_uncalib_descriptor_model` for each match is a 3x3 matrix `HomMat2D`, which describes a 2D projection of model points to search image points and is represented by a tuple of 9 elements in row-major order. If more matches of the searched object (template) appear and pass the `MinScore` criterion, the resulting multiple homographies are concatenated. The number of objects actually found is then equal to $\text{NumObjects} = |\text{HomMat2D}|/9$.

The detection process is divided into three parts. **First**, interest points are extracted from the search image (only inside the domain of the search image). This is done using the point detector and its parameters selected once during the generation of the model. However, `DetectorParamName` and `DetectorParamValue` can be used to specify different detector parameter values during the `find_uncalib_descriptor_model` call. By changing these parameters, it is possible to adjust to illumination changes between the model generation and the online detection. However, it is recommended to use the same values used to create the model (pass an empty tuple).

**The second step** of the detection process is to calculate correspondences between the model points and the points that were detected. The run time parameters of the descriptor can be adjusted with `DescriptorParamName` and `DescriptorParamValue`:

- **'min_score_descr'**: is the minimal classifier score for an interest point to be regarded as a potential match. The score function is between 0.0 and 1.0, but typically only values between 0.0 and 0.1 make sense. Increasing `min_score_descr` can increase significantly the detection speed. Note, however, that using `min_score_descr` might have negative effect on the robustness of the detection process, especially when only few points can be found. Typical values are [0.0 ... 0.1], default value is 0.0.

- **'guided_matching'**: enhances the accuracy of the object recognition when switched on. Note that it increases the computational costs up to 10% in some cases. Possible values are ['on', 'off'], default value is 'on'.

**The last step** is the estimation of a homography that describes the point correspondences. The homography is a 2D projection, which describes a transformation from model points to points in `Image`. Here, Natural 3D Markers (N3Ms) are utilized to identify robustly the point correspondences (see references).

Additionally to the estimated homography in `HomMat2D`, the operator returns one or more `Score` estimations per object instance as specified by the user in a tuple `ScoreType`. Currently the following values for `ScoreType` are supported:

- **'num_points'**: number of point correspondences per instance. An object instance should be considered good, if it has 10 or more point correspondences with the model. Fewer points are insufficient, because any random 4 point correspondences define a mathematically correct homography between two images.

- **'inlier_ratio'**: the ratio of the number of point correspondences to the number of model points. Although this value can have values of [0.0 ... 1.0], it is rather unlikely that this ratio can reach 1.0. Yet, objects having inlier ratio less than 0.1, should be disregarded.

Note that the resulting scores for more than one object instance will be concatenated in `Score`, such that $|\text{Score}| = \text{NumObjects}*|\text{ScoreType}|$.

The point correspondences for each object can be queried with `get_descriptor_model_points`.

**Attention**

Note that the domain of the search image should contain the whole object to be searched for because interest points are only extracted inside the domain of the search image. This means that if the domain does not contain the full object to be searched for, the resulting `Score` will decrease. Note also that matches may be found even if the reference point (origin) of the model lies outside of the domain of the search image. Both is in contrast to shape-based matching, where the domain of the search image defines the search space for the reference point of the model.
Parameters

- **Image** (input_object) ........................................... singlechannelimage $\sim$ object : byte / uint2
  Input image where the model should be found.

- **ModelID** (input_control) ........................................... descriptor_model $\sim$ handle
  The handle to the descriptor model.

- **DetectorParamName** (input_control) ................................... attribute.name-array $\sim$ string
  The detector’s parameter names.
  **Default value:** []
  **List of values:** DetectorParamName $\in$ ['alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold']

- **DetectorParamValue** (input_control) ................................... attribute.value-array $\sim$ integer / real / string
  Values of the detector’s parameters.
  **Default value:** []
  **Suggested values:** DetectorParamValue $\in$ {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off'}

- **DescriptorParamName** (input_control) ................................... attribute.name-array $\sim$ string
  The descriptor’s parameter names.
  **Default value:** []
  **List of values:** DescriptorParamName $\in$ ['min_score_descr', 'guided_matching']

- **DescriptorParamValue** (input_control) ................................... attribute.value-array $\sim$ real / integer / string
  Values of the descriptor’s parameters.
  **Default value:** []
  **Suggested values:** DescriptorParamValue $\in$ {0.0, 0.001, 0.005, 0.01, 'on', 'off'}

- **MinScore** (input_control) ........................................... real(-array) $\sim$ real
  Minimum score of the instances of the models to be found.
  **Default value:** 0.2
  **Suggested values:** MinScore $\in$ {0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  **Typical range of values:** $0 \leq$ MinScore $\leq$ 1

- **NumMatches** (input_control) ........................................... integer $\sim$ integer
  Maximal number of found instances.
  **Default value:** 1
  **Suggested values:** NumMatches $\in$ {1, 2, 3, 4}
  **Restriction:** NumMatches $\geq$ 1

- **ScoreType** (input_control) ........................................... string(-array) $\sim$ string
  Score type to be evaluated in Score.
  **Default value:** 'num_points'
  **List of values:** ScoreType $\in$ ['num_points', 'inlier_ratio']

- **HomMat2D** (output_control) ........................................... hom_mat2d(-array) $\sim$ real
  Homography between model and found instance.

- **Score** (output_control) ........................................... number(-array) $\sim$ real / integer
  Score of the found instances according to the ScoreType input.

Example

```plaintext
create_uncalib_descriptor_model (ImageReduced, 'harris', [], [], \ 
  [], [], 42, ModelID)
get_descriptor_model_params (ModelID, DetectorType, \ 
  DetectorParamName, DetectorParamValue, \ 
  DescriptorParamName, DescriptorParamValue)
write_descriptor_model (ModelID, 'simple_example.dsm')
read_descriptor_model ('simple_example.dsm', ModelID)
find_uncalib_descriptor_model (SearchImage, ModelID, [], [], [], 
  [], [], 0.2, 1, \ 
  ['num_points', 'inlier_ratio'], HomMat2D, Score)
```
18.4. DESCRIPTOR-BASED

Module
Matching

get_descriptor_model_origin ( : : ModelID : Row, Column )

Return the origin of a descriptor model.

The operator get_descriptor_model_origin returns the origin (reference point) of the descriptor model ModelID. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the descriptor model with create_uncalib_descriptor_model, or create_calib_descriptor_model. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ModelID (input_control) . descriptor_model ~ handle
  Handle of a descriptor model.
- Row (output_control) . real ~ real / integer
  Position of origin in row direction.
- Column (output_control) . real ~ real / integer
  Position of origin in column direction.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module
Matching

get_descriptor_model_params ( : : ModelID : DetectorType, DetectorParamName, DetectorParamValue, DescriptorParamName, DescriptorParamValue )

Return the parameters of a descriptor model.
The operator `get_descriptor_model_params` allows to access the parameters of a descriptor model that was created with `create_uncalib_descriptor_model` or `create_calib_descriptor_model`. Therefore, a handle of a descriptor model must be passed in `ModelID`. The operator returns in `DetectorType`, `DetectorParamName` and `DetectorParamValue` the type and parametrization of the detector. In `DescriptorType`, `DescriptorParamName` and `DescriptorParamValue` the respective descriptor is returned.

An application for this operator is the possibility to query the parameters that where used in a stored model. As the operator needs a handle to a descriptor model, it has to be loaded first by using `read_descriptor_model`.

---

**Parameters**

- **ModelID** (input_control) .......................... descriptor_model ~ handle
  The object handle to the descriptor model.
- **DetectorType** (output_control) ...................... string ~ string
  The type of the detector.
- **DetectorParamName** (output_control) ................. attribute.name-array ~ string
  The detectors parameter names.
- **DetectorParamValue** (output_control) ................ attribute.value-array ~ integer / real / string
  Values of the detectors parameters.
- **DescriptorParamName** (output_control) ............... attribute.name-array ~ string
  The descriptors parameter names.
- **DescriptorParamValue** (output_control) .............. attribute.value-array ~ integer / real / string
  Values of the descriptors parameters.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**get_descriptor_model_points**

`{ : : ModelID, Set, Subset : Row, Column }`

Query the interest points of the descriptor model or the last processed search image.

With the operator `get_descriptor_model_points` interest points of the descriptor model or the last processed search image can be queried. It requires a `ModelID` returned by `create_uncalib_descriptor_model, create_calib_descriptor_model, or read_descriptor_model`.

The interest points stored in the model can always be queried by setting `Set` to 'model' and `Subset` to 'all'. If a `find_uncalib_descriptor_model` or `find_calib_descriptor_model` precedes, with `get_descriptor_model_points` the interest points of the last search image can be queried as well by setting `Set` to 'search' and `Subset` to 'all'. Additionally, the matched (corresponding) points for each object instance found can be queried by setting `Set` to 'model' or 'search' (for the correspondences on the model or search image side, respectively) and `Subset` to the result number of the instance. The image coordinates of the queried points are returned in `Row` and `Column`. 

---

HALCON/HDevelop Reference Manual, 2020-11-10
18.4. DESCRIPTOR-BASED

Parameters

- **ModelID** (input_control) .......................................................... descriptor_model \(\Rightarrow\) handle
  The handle to the descriptor model.
- **Set** (input_control) ................................................................. string \(\Rightarrow\) string
  Set of interest points.
  **Default value:** 'model'
  **List of values:** Set \(\in\) \{'model', 'search'\}
- **Subset** (input_control) ............................................................. integer \(\Rightarrow\) integer / string
  Subset of interest points.
  **Default value:** 'all'
  **Suggested values:** Subset \(\in\) \{'all', 0, 1, 2\}
- **Row** (output_control) .............................................................. point.y-array \(\Rightarrow\) real / integer
  Row coordinates of interest points.
- **Column** (output_control) ......................................................... point.x-array \(\Rightarrow\) real / integer
  Column coordinates of interest points.

Example

```c
create_uncalib_descriptor_model (Template,'harris',[],[],[],[],42, \ ModelID)
```
* Model points can be queried from a model, even if just created
* find_uncalib_descriptor_model (Image,ModelID,[],[],[],[],0.2,1, \ 'num_points',HomMat2D,Score)
  * Search points can be queried only after a
  * find_[un]calib_descriptor_model was executed
  * Additionally, correspondences for the results can be queried
  NumObjects := |HomMat2D|/9
  for I := 0 to NumObjects-1 by 1
    * Query corresponding points in the model
      get_descriptor_model_points (ModelID,'model',I, \ CorrModelRow,CorrModelColumn)
    * Query corresponding points in the search image
      get_descriptor_model_points (ModelID,'search',I, \ CorrSearchRow,CorrSearchColumn)
    * Those points are typically for visualizational purposes
      gen_cross_contour_xld (CrossModel,CorrModelRow,CorrModelColumn, \ 6,0.78)
      gen_cross_contour_xld (CrossSearch,CorrSearchRow,CorrSearchColumn, \ 6,0.79)
    * ....
  endfor
```

Execution Information

Module

Matching

get_descriptor_model_results ( : : ModelID, ObjectID,
                              ResultNames : Results )

Query alphanumerical results that were accumulated during descriptor-based matching.

The operator get_descriptor_model_results allows to access alphanumerical results of the descriptor based matching process. The results are stored in a descriptor based model specified by ModelID. ObjectID specifies for which object the results should be returned. The objects are 0-based indexed and in the same order as they are detected by find_uncalib_descriptor_model or find_calib_descriptor_model, respectively. Results can be queried for all objects at once by specifying 'all' in ObjectID, if they are single valued (e.g., ResultNames='num_points' or ResultNames='inlier_ratio').

The results returned in Results can be selected by setting ResultNames to:

'num_points': number of object points that correspond to model points.
'inlier_ratio': ratio of successfully matched object points relative to all descriptor model points.
'homography': a 3x3 projective transformation matrix which transforms model points into object points. Note that the result of the mapping depends on the selected model origin (see set_descriptor_model_origin).
'pose': returns the estimated object pose. Note that this result can only be queried after find_calib_descriptor_model was called.
'point_classification': returns concatenated triads representing the classification results for the interest points extracted from the search image during the last call of find_uncalib_descriptor_model or find_calib_descriptor_model. Each triad consists of a search point index on the first, a model point index on the second, and a classification score on the third position. The search and model point indices correspond to the point coordinates returned by get_descriptor_model_points with the parameter Subset set to 'all' and the parameter Set set to 'search' and 'model', respectively. If a number is passed in ObjectID only the classification results for the points matched to this object are returned. If 'all' is passed in ObjectID the classification results for all points, including the points not matched to any object, are returned. The triads are sorted in descending order with respect to their score. Points having a score less than the value of the descriptor parameter 'min_score_descr' (see find_calib_descriptor_model or find_uncalib_descriptor_model) are rejected and are not listed in the resulting classification results.

Parameters

- ModelID (input_control) : descriptor_model ~ handle
Handle of a descriptor model.

- ObjectID (input_control) : ObjectID ~ integer / string
Handle of the object for which the results are queried.
  Default value: 'all'
  Suggested values: ObjectID ∈ {'all', 0, 1, 2, 3}

- ResultNames (input_control) : ResultNames ~ string
Name of the results to be queried.
  Default value: 'num_points'
  List of values: ResultNames ∈ {'num_points', 'inlier_ratio', 'homography', 'pose', 'point_classification'}

- Results (output_control) : Results ~ attribute.value(-array)
Returned results.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

### read_descriptor_model

*( : : FileName : ModelID )*

**Read a descriptor model from a file.**

The operator `read_descriptor_model` reads a descriptor model, which has been written with `write_descriptor_model`, from the file `FileName`. The default HALCON file extension for the descriptor model is `.dsm`.

**Parameters**

- **FileName** *(input_control)*: filename.read  ~> string
  File name.
  *File extension:*. `.dsm`

- **ModelID** *(output_control)*: descriptor_model  ~> handle
  Handle of the model.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors
find_uncalib_descriptor_model, find_calib_descriptor_model

Module

### serialize_descriptor_model

*( : : ModelID : SerializedItemHandle )*

**Serialize a descriptor model.**

`serialize_descriptor_model` serializes the data of a descriptor model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_descriptor_model` is converted to a serialized item. The descriptor model is defined by the handle `ModelID`. The serialized descriptor model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_descriptor_model`.

**Parameters**

- **ModelID** *(input_control)*: descriptor_model  ~> handle
  Handle of a model to be saved.

- **SerializedItemHandle** *(output_control)*: serialized_item  ~> handle
  Handle of the serialized item.
If the parameters are valid, the operator `serialize_descriptor_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

## set_descriptor_model_origin ( : : ModelID, Row, Column : )

Sets the origin of a descriptor model.

The operator `set_descriptor_model_origin` sets the origin (reference point) of the descriptor model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the descriptor model with `create_uncalib_descriptor_model` or `create_calib_descriptor_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity. The new setting affects the succeeding `find_uncalib_descriptor_model` and `find_calib_descriptor_model` calls.

### Parameters

- **ModelID** (input_control)
  - Type: Descriptor model handle
  - Access: read
  - Description: Handle of a descriptor model.
  
- **Row** (input_control)
  - Type: Real
  - Access: read
  - Description: Translation of origin in row direction.
  
  **Default value:** 0

- **Column** (input_control)
  - Type: Real
  - Access: read
  - Description: Translation of origin in column direction.
  
  **Default value:** 0

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

`create_uncalib_descriptor_model`, `create_calib_descriptor_model`, `read_descriptor_model`
18.5 Shape-Based

adapt_shape_model_high_noise ( ImageReduced : : ModelID, GenParam : ResultDict )

Adapt a shape model’s parameters for high noise images.

adapt_shape_model_high_noise adapts the parameters of a shape model ModelID for high noise images and returns them in ResultDict. Based on a sample search image ImageReduced, the optimal values of the shape model’s parameters are estimated and adapted in the model. The domain of ImageReduced should contain the model and surrounding background, such that the typical noise is presented to the algorithm. With GenParam the parameters to be estimated can be controlled. Currently, the operator supports the estimation of the lowest pyramid level used in the matching step. Accordingly, the value ‘all’ or ‘lowest_level’ should be provided to GenParam. Please note that the operator changes the shape model ModelID such that it uses the estimated lowest pyramid level in subsequent calls of, e.g., find_shape_model. The estimated lowest pyramid level can be overridden in subsequent find calls as explained in the documentation of the different find operators, e.g., find_shape_model.
Parameters

- **ImageReduced** (input_object) .................................................(multichannel-)image ~ object : byte / uint2
  Sample search image with reduced domain.
- **ModelID** (input_control) ..................................................... shape_model ~ handle
  Handle of the shape model.
- **GenParam** (input_control) ................................................... string-array ~ string
  Parameters to be estimated.
  Default value: ‘all’
  List of values: GenParam ∈ [’lowest_level’, ‘all’]
- **ResultDict** (output_control) .................................................. dict ~ handle
  Dictionary with the estimated parameter values.

If the parameters are valid, the operator `adapt_shape_model_high_noise` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

- `create_shape_model`, `create_scaled_shape_model`, `create_aniso_shape_model`

Possible Successors

- `find_shape_model`, `find_scaled_shape_model`, `find_aniso_shape_model`, `find_shape_models`, `find_scaled_shape_models`, `find_aniso_shape_models`

Module

**clear_shape_model** ( : : ModelID : )

Free the memory of a shape model.

The operator `clear_shape_model` frees the memory of a shape model that was created by `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. After calling `clear_shape_model`, the model can no longer be used. The handle `ModelID` becomes invalid.

Parameters

- **ModelID** (input_control) ..................................................... shape_model ~ handle
  Handle of the model.

If the handle of the model is valid, the operator `clear_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_shape_model, create_scaled_shape_model, create_aniso_shape_model,
read_shape_model, write_shape_model

Matching

create_aniso_shape_model ( Template : : NumLevels, AngleStart,
AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep,
ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, Contrast,
MinContrast : ModelID )

Prepare an anisotropically scaled shape model for matching.

The operator create_aniso_shape_model prepares a template, which is passed in the image Template, as an anisotropically scaled shape model used for matching. The ROI of the model is passed as the domain of Template.

The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_aniso_shape_model. The center of gravity of the domain (region) of the model image Template is used as the origin (reference point) of the model. A different origin can be set with set_shape_model_origin. The model is generated using multiple image pyramid levels and is stored in memory. If a complete regeneration of the model is selected (see below), the model is generated at multiple rotations and anistropic scales (i.e., independent scales in the row and column direction) on each level. The model can be extended by clutter parameters with set_shape_model_clutter.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of inspect_shape_model. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_aniso_shape_model returns with an error message.

If NumLevels is set to 'auto' (or 0 for backwards compatibility), create_aniso_shape_model determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_aniso_shape_model determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_aniso_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_aniso_shape_model may increase. In these cases, the number of pyramid levels should be selected using the output of inspect_shape_model.

AngleStart, AngleExtent and AngleStep: The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by find_aniso_shape_model. The parameter AngleStep determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in find_aniso_shape_model, this parameter specifies the accuracy that is achievable for the angles in find_aniso_shape_model. AngleStep should be chosen based on the size of the object. Smaller
models do not have many different discrete rotations in the image, and hence AngleStep should be chosen larger for smaller models. If AngleExtent is not an integer multiple of AngleStep, AngleStep is modified accordingly.

To ensure that for model instances without rotation angle values of exactly 0.0 are returned by find_aniso_shape_model, the range of possible rotations is modified as follows: If there is no positive integer value n such that AngleStart plus n times AngleStep is exactly 0.0, AngleStart is decreased by up to AngleStep and AngleExtent is increased by AngleStep.

ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, ScaleRStep and ScaleCStep: The parameters ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, ScaleRStep and ScaleCStep determine the range of possible anisotropic scales of the model in the row and column direction. A scale of 1 in both scale factors corresponds to the original size of the model. The parameters ScaleRStep and ScaleCStep determine the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in find_aniso_shape_model, these parameters specify the accuracy that is achievable for the scales in find_aniso_shape_model. Like AngleStep, ScaleRStep and ScaleCStep should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of ScaleRStep and ScaleCStep, ScaleRStep and ScaleCStep are modified accordingly.

To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by find_aniso_shape_model, the range of possible scales is modified as follows: If there are no positive integer values n and m such that ScaleRMin plus n times ScaleRStep is exactly 1.0 and ScaleCMin plus m times ScaleCStep is exactly 1.0, ScaleRMin and ScaleCMin are decreased by up to ScaleRStep and ScaleCStep, respectively, and ScaleRMax and ScaleCMax are increased such that the range of possible scales is increased by ScaleRStep and ScaleCStep, respectively.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_aniso_shape_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If Optimization is set to 'auto', create_aniso_shape_model automatically determines the reduction of the number of model points.

Metric: The parameter Metric determines the conditions under which the model is recognized in the image.

If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object is also found if it is darker than the background. The runtime of find_aniso_shape_model will increase slightly in this case.

If Metric = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of find_aniso_shape_model increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with create_aniso_shape_model, and to match them simultaneously with find_aniso_shape_model.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If Metric = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of find_aniso_shape_model can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for Metric = 'ignore_color_polarity' the number of channels in the model creation with create_aniso_shape_model and in the search with
find_aniso_shape_model can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

**Contrast:** The parameter Contrast determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. Contrast should be chosen such that only the significant features of the template are used for the model. Contrast can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in edges_image. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see hysteresis_threshold. Optionally, Contrast can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in Contrast. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with inspect_shape_model.

If Contrast is set to 'auto', create_aniso_shape_model determines the three above described values automatically. Besides, only the contrast ('auto_contrast'), the hysteresis thresholds ('auto_contrast_hyst'), or the minimum size ('auto_min_size') can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, ['auto_contrast','auto_min_size'] is passed, both the contrast and the minimum size are determined automatically. If ['auto_min_size',20,30] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30. etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with determine_shape_model_params and subsequently verified using inspect_shape_model before calling create_aniso_shape_model. Note that MinContrast influences the automatic contrast estimation, and hence also the estimation of the minimum size.

**MinContrast:** With MinContrast, it can be determined which contrast the model must at least have in the recognition performed by find_aniso_shape_model. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast should be set to 17. Obviously, MinContrast must be smaller than Contrast. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_aniso_shape_model.

If MinContrast is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using get_shape_model_params.

**Complete pregeneration of the model**

Optionally, a second value can be passed in Optimization. This value determines whether the model is pregenerated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models',...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model
find_aniso_shape_model

The time to find the object will be much smaller. Since angles can be determined with subpixel resolution by the model completely fits into the main memory, because this avoids paging by the operating system, and hence AngleExtent must be enlarged or ScaleCStep or AngleStep steps, the number of scale steps, and the number of points in the model. Hence, if find_aniso_shape_model transformed models. For example, if the model is not pregenerated completely, find_aniso_shape_model typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if AngleStep, ScaleRStep, or ScaleCStep are too small or AngleExtent or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, AngleStep, ScaleRStep, or ScaleCStep must be enlarged or AngleExtent or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_aniso_shape_model, AngleStep ≥ 1° and ScaleRStep, ScaleCStep ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' or ScaleRStep, ScaleCStep = 'auto' (or 0 for backwards compatibility in both cases) is selected, create_aniso_shape_model automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_aniso_shape_model. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

--- Parameters ---

- **Template** (input_object) : (multichannel-)image → object : byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) : integer → integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: NumLevels ∈ ['auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

- **AngleStart** (input_control) : angle.rad → real
  Smallest rotation of the pattern.
  Default value: -0.39
  Suggested values: AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]

- **AngleExtent** (input_control) : angle.rad → real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent ∈ [6.29, 3.14, 1.57, 0.79, 0.39]
  Restriction: AngleExtent ≥ 0

- **AngleStep** (input_control) : angle.rad → real / string
  Step length of the angles (resolution).
  Default value: 'auto'
  Suggested values: AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]
  Restriction: AngleStep >= 0 && AngleStep <= pi / 16

- **ScaleRMin** (input_control) : number → real
  Minimum scale of the pattern in the row direction.
  Default value: 0.9
  Suggested values: ScaleRMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: ScaleRMin > 0
18.5. SHAPE-BASED

- **ScaleRMax** (input_control) ...................................................... number ~ real
  Maximum scale of the pattern in the row direction.
  Default value: 1.1
  Suggested values: ScaleRMax ∈ [1.0, 1.1, 1.2, 1.3, 1.4, 1.5]
  Restriction: ScaleRMax >= ScaleRMin

- **ScaleRStep** (input_control) ...................................................... number ~ real / string
  Scale step length (resolution) in the row direction.
  Default value: ‘auto’
  Suggested values: ScaleRStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleRStep >= 0

- **ScaleCMin** (input_control) ...................................................... number ~ real
  Minimum scale of the pattern in the column direction.
  Default value: 0.9
  Suggested values: ScaleCMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]
  Restriction: ScaleCMin > 0

- **ScaleCMax** (input_control) ...................................................... number ~ real
  Maximum scale of the pattern in the column direction.
  Default value: 1.1
  Suggested values: ScaleCMax ∈ [1.0, 1.1, 1.2, 1.3, 1.4, 1.5]
  Restriction: ScaleCMax >= ScaleCMin

- **ScaleCStep** (input_control) ...................................................... number ~ real / string
  Scale step length (resolution) in the column direction.
  Default value: ‘auto’
  Suggested values: ScaleCStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
  Restriction: ScaleCStep >= 0

- **Optimization** (input_control) ................................................ string(-array) ~ string
  Kind of optimization and optionally method used for generating the model.
  Default value: ‘auto’
  List of values: Optimization ∈ ['auto', 'none', 'point_reduction_low', 'point_reduction_medium',
  'point_reduction_high', 'pregeneration', 'no_pregeneration']

- **Metric** (input_control) ......................................................... string ~ string
  Match metric.
  Default value: ‘use_polarity’
  List of values: Metric ∈ ['use_polarity', 'ignore_global_polarity', 'ignore_local_polarity',
  'ignore_color_polarity']

- **Contrast** (input_control) ...................................................... number(-array) ~ integer / string
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum
  size of the object parts.
  Default value: ‘auto’
  Suggested values: Contrast ∈ ['auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30,
  40, 60, 80, 100, 120, 140, 160]

- **MinContrast** (input_control) ................................................... number ~ integer / string
  Minimum contrast of the objects in the search images.
  Default value: ‘auto’
  Suggested values: MinContrast ∈ ['auto', 1, 2, 3, 5, 7, 10, 20, 30, 40]
  Restriction: MinContrast < Contrast

- **ModelID** (output_control) ....................................................... shape_model ~ handle
  Handle of the model.

--- Result ---

If the parameters are valid, the operator `create_aniso_shape_model` returns the value 2 (H_MSG_TRUE).
If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model
contains too few points, the error 8510 is raised.

--- Execution Information ---

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```
create_aniso_shape_model_xld ( Contours : : NumLevels,
    AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,
    ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,
    Metric, MinContrast : : ModelID )
```

Prepare an anisotropically scaled shape model for matching from XLD contours.

The operator `create_aniso_shape_model_xld` creates an anisotropically scaled shape model used for matching from the XLD contours passed in `Contours`. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator `create_aniso_shape_model`, which creates a shape model from a template image, the operator `create_aniso_shape_model_xld` creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_aniso_shape_model`. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and anisotropic scales (i.e., independent scales in the row and column direction) on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

**NumLevels**: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_aniso_shape_model_xld` returns with an error message. If `NumLevels` is set to 'auto', `create_aniso_shape_model_xld` determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_aniso_shape_model_xld` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_aniso_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_aniso_shape_model` may increase. In these cases, the number of pyramid levels should be selected manually.

**AngleStart, AngleExtent and AngleStep**: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the object can occur in the image. Note that the object can only
be found in this range of angles by `find_aniso_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_aniso_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_aniso_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

**ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, ScaleRStep and ScaleCStep:** The parameters `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, `ScaleCMax`, `ScaleRStep` and `ScaleCStep` determine the range of possible anisotropic scales of the object in the row and column direction. A scale of 1 in both scale factors corresponds to the original size of the model. The parameters `ScaleRStep` and `ScaleCStep` determine the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, these parameters specify the accuracy that is achievable for the scales in `find_aniso_shape_model`. Like `AngleStep`, `ScaleRStep` and `ScaleCStep` should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of `ScaleRStep` and `ScaleCStep`, `ScaleRStep` and `ScaleCStep` are modified accordingly.

To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_aniso_shape_model`, the range of possible scales is modified as follows: If there are no positive integer values n and m such that `ScaleRMin` plus n times `ScaleRStep` is exactly 1.0 and `ScaleCMin` plus m times `ScaleCStep` is exactly 1.0, `ScaleRMin` and `ScaleCMin` are decreased by up to `ScaleRStep` and `ScaleCStep`, respectively, and `ScaleRMax` and `ScaleCMax` are increased such that the range of possible scales is increased by `ScaleRStep` and `ScaleCStep`, respectively. Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

**Optimization:** For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `'none'`. If `Optimization` = `'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_aniso_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to `'auto'`, `create_aniso_shape_model_xld` automatically determines the reduction of the number of model points.

**Metric:** The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric` = `'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric` = `'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_aniso_shape_model` will increase slightly in this case.

Note that the metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the edges. This attribute is available for contours created, e.g., with `edges_sub_pix` with the parameter `Method` set to, e.g., `'canny'`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

If `Metric` = `'ignore_local_polarity'`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_aniso_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_aniso_shape_model_xld`, and to match them simultaneously with `find_aniso_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).
If Metric = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance which channels the object is visible. In this mode, the runtime of find_aniso_shape_model can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for Metric = 'ignore_color_polarity' the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. For more information about contour attributes like 'edge_direction' see get_contour_attrib_xld. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

MinContrast: With MinContrast, it can be determined which contrast the object edges must at least have in the recognition performed by find_aniso_shape_model. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast should be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_aniso_shape_model.

Complete pregeneration of the model

Optionally, a second value can be passed in Optimization. This value determines whether the model is pregenerated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models',...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, find_aniso_shape_model typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if AngleStep, ScaleRStep, or ScaleCStep are too small or AngleExtent or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, AngleStep, ScaleRStep, or ScaleCStep must be enlarged or AngleExtent or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_aniso_shape_model.AngleStep ≥ 1° and ScaleRStep,ScaleCStep ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' or ScaleRStep,ScaleCStep = 'auto' is selected, create_aniso_shape_model_xld automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in...
18.5. SHAPE-BASED

`find_aniso_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

**Attention**

The XLD contours passed in `Contours` should have been scaled to approximately the average size of the object in the search images. This means that the products `ScaleRMin × ScaleRMax` and `ScaleCMin × ScaleCMax` should be approximately equal to 1.

Note that, in contrast to the operator `create_aniso_shape_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling `create_aniso_shape_model_xld` with the operator `select_contours_xld`.

### Parameters

- **Contours** (input_object) ................................................. `xld_cont(-array)`  ~ object
  Input contours that will be used to create the model.

- **NumLevels** (input_control) ................................. integer  ~ integer / string
  Maximum number of pyramid levels.
  Default value: `'auto'`
  List of values: `NumLevels ∈ ['auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]`

- **AngleStart** (input_control) .............................................. angle.rad  ~ real
  Smallest rotation of the pattern.
  Default value: `-0.39`
  Suggested values: `AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]`

- **AngleExtent** (input_control) .............................................. angle.rad  ~ real
  Extent of the rotation angles.
  Default value: `0.79`
  Suggested values: `AngleExtent ∈ [6.29, 3.14, 1.57, 0.79, 0.39]`
  Restriction: `AngleExtent >= 0`

- **AngleStep** (input_control) .............................................. angle.rad  ~ real / string
  Step length of the angles (resolution).
  Default value: `'auto'`
  Suggested values: `AngleStep ∈ ['auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873]`
  Restriction: `AngleStep > 0` && `AngleStep <= pi / 16`

- **ScaleRMin** (input_control) ............................................. number  ~ real
  Minimum scale of the pattern in the row direction.
  Default value: `0.9`
  Suggested values: `ScaleRMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  Restriction: `ScaleRMin > 0`

- **ScaleRMax** (input_control) ............................................. number  ~ real
  Maximum scale of the pattern in the row direction.
  Default value: `1.1`
  Suggested values: `ScaleRMax ∈ [1.0, 1.1, 1.2, 1.3, 1.4, 1.5]`
  Restriction: `ScaleRMax >= ScaleRMin`

- **ScaleRStep** (input_control) ............................................. number  ~ real / string
  Scale step length (resolution) in the row direction.
  Default value: `'auto'`
  Suggested values: `ScaleRStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]`
  Restriction: `ScaleRStep > 0`

- **ScaleCMin** (input_control) ............................................. number  ~ real
  Minimum scale of the pattern in the column direction.
  Default value: `0.9`
  Suggested values: `ScaleCMin ∈ [0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`
  Restriction: `ScaleCMin > 0`

- **ScaleCMax** (input_control) ............................................. number  ~ real
  Maximum scale of the pattern in the column direction.
  Default value: `1.1`
  Suggested values: `ScaleCMax ∈ [1.0, 1.1, 1.2, 1.3, 1.4, 1.5]`
  Restriction: `ScaleCMax >= ScaleCMin`

HALCON 20.11.0.0
\*\*\* ScaleCStep (input_control) \*\*\* number  real / string
Scale step length (resolution) in the column direction.
**Default value:** ‘auto’
**Suggested values:** ScaleCStep ∈ ['auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2]
**Restriction:** ScaleCStep > 0
\*\*\* Optimization (input_control) \*\*\* string(-array)  string
Kind of optimization and optionally method used for generating the model.
**Default value:** ‘auto’
**List of values:** Optimization ∈ ['auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration']
\*\*\* Metric (input_control) \*\*\* string  string
Match metric.
**Default value:** ‘ignore_local_polarity’
**List of values:** Metric ∈ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
\*\*\* MinContrast (input_control) \*\*\* number  integer
Minimum contrast of the objects in the search images.
**Default value:** 5
**Suggested values:** MinContrast ∈ {1, 2, 3, 5, 7, 10, 20, 30, 40}
\*\*\* ModelID (output_control) \*\*\* shape_model  handle
Handle of the model.
**Result**
If the parameters are valid, the operator create_aniso_shape_model_xld returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter NumLevels is chosen such that the model contains too few points, the error 8510 is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

```
create_scaled_shape_model (Template : NumLevels, AngleStart, 
  AngleExtent, AngleStep, ScaleMin, ScaleMax, ScaleStep, 
  Optimization, Metric, Contrast, MinContrast : ModelID )
```

**Prepare an isotropically scaled shape model for matching.**

The operator create_scaled_shape_model prepares a template, which is passed in the image Template, as an isotropically scaled shape model used for matching. The ROI of the model is passed as the domain of Template.
The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_scaled_shape_model. The center of gravity of the domain (region) of the model image Template is used as the origin (reference point) of the model. A different origin can be set with set_shape_model_origin. The model is generated using multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and scales on each level. The model can be extended by clutter parameters with set_shape_model_clutter.

Input parameters in detail

**NumLevels:** The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of inspect_shape_model. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_scaled_shape_model returns with an error message.

If NumLevels is set to 'auto' (or 0 for backwards compatibility), create_scaled_shape_model determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_scaled_shape_model determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_scaled_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_scaled_shape_model may increase. In these cases, the number of pyramid levels should be selected using the output of inspect_shape_model.

**AngleStart, AngleExtent and AngleStep:** The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by find_scaled_shape_model. The parameter AngleStep determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in find_scaled_shape_model, this parameter specifies the accuracy that is achievable for the angles in find_scaled_shape_model. AngleStep should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence AngleStep should be chosen larger for smaller models. If AngleExtent is not an integer multiple of AngleStep, AngleStep is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by find_scaled_shape_model, the range of possible rotations is modified as follows: If there is no positive integer value n such that AngleStart plus n times AngleStep is exactly 0.0, AngleStart is decreased by up to AngleStep and AngleExtent is increased by AngleStep.

**ScaleMin, ScaleMax and ScaleStep:** The parameters ScaleMin and ScaleMax determine the range of possible scales (sizes) of the model. A scale of 1 corresponds to the original size of the model. The parameter ScaleStep determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in find_scaled_shape_model, this parameter specifies the accuracy that is achievable for the scales in find_scaled_shape_model. Like AngleStep, ScaleStep should be chosen based on the size of the object. If the range of scales is not an integer multiple of ScaleStep, ScaleStep is modified accordingly. To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by find_scaled_shape_model, the range of possible scales is modified as follows: If there is no positive integer value n such that ScaleMin plus n times ScaleStep is exactly 1.0, ScaleMin is decreased by up to ScaleStep and ScaleMax is increased such that the range of possible scales is increased by ScaleStep.

**Optimization:** For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_scaled_shape_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If Optimization is set to 'auto', create_scaled_shape_model automatically determines the reduction of the number of model points.
Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_scaled_shape_model` will increase slightly in this case.

If `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_scaled_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_scaled_shape_model`, and to match them simultaneously with `find_scaled_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_scaled_shape_model` can also increase significantly. The metric `ignore_color_polarity` can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as `ignore_local_polarity`. It should be noted that for `Metric = 'ignore_color_polarity'` the number of channels in the model creation with `create_scaled_shape_model` and in the search with `find_scaled_shape_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Contrast: The parameter `Contrast` determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model. `Contrast` can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, `Contrast` can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in `Contrast`. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with `inspect_shape_model`.

If `Contrast` is set to `auto`, `create_scaled_shape_model` determines the three above described values automatically. Besides, only the contrast (`auto_contrast`), the hysteresis thresholds (`auto_contrast_hyst`), or the minimum size (`auto_min_size`) can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, `[auto_contrast,auto_min_size]` is passed, both the contrast and the minimum size are determined automatically. If `[auto_min_size,20,30]` is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_shape_model_params` and subsequently verified using `inspect_shape_model` before calling `create_scaled_shape_model`. Note that `MinContrast` influences the automatic contrast estimation, and hence also the estimation of the minimum size.

MinContrast: With `MinContrast`, it can be determined which contrast the model must at least have in the recognition performed by `find_scaled_shape_model`. In other words, this parameter separates the
model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast should be set to 17. Obviously, MinContrast must be smaller than Contrast. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_scaled_shape_model.

If MinContrast is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using get_shape_model_params.

Complete pregeneration of the model

Optionally, a second value can be passed in Optimization. This value determines whether the model is pre-generated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models', ...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, find_scaled_shape_model typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if AngleStep or ScaleStep are too small or AngleExtent or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep or ScaleStep must be enlarged or AngleExtent or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_scaled_shape_model, AngleStep ≥ 1° and ScaleStep ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' or ScaleStep = 'auto' (or 0 for backwards compatibility in both cases) is selected, create_scaled_shape_model automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_scaled_shape_model. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

</table>
- **NumLevels** (input_control) .......................................................... integer ~ integer / string
  Maximum number of pyramid levels.
  Default value: ‘auto’
  List of values: NumLevels ∈ {‘auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) ...................................................... angle.rad ~ real
  Smallest rotation of the pattern.
  Default value: -0.39
  Suggested values: AngleStart ∈ [-3.14, -1.57, -0.79, -0.39, -0.20, 0.0]
  Restriction: AngleStart ≥ 0

- **AngleExtent** (input_control) .................................................... angle.rad
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}
  Restriction: AngleExtent ≥ 0

- **AngleStep** (input_control) ...................................................... angle.rad / string
  Step length of the angles (resolution).
  Default value: ‘auto’
  Suggested values: AngleStep ∈ {‘auto’, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
  Restriction: AngleStep ≥ 0 && AngleStep ≤ \(\pi/16\)

- **ScaleMin** (input_control) .............................................................. number ~ real
  Minimum scale of the pattern.
  Default value: 0.9
  Suggested values: ScaleMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: ScaleMin > 0

- **ScaleMax** (input_control) .............................................................. number ~ real
  Maximum scale of the pattern.
  Default value: 1.1
  Suggested values: ScaleMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
  Restriction: ScaleMax ≥ ScaleMin

- **ScaleStep** (input_control) .............................................................. number ~ real / string
  Scale step length (resolution).
  Default value: ‘auto’
  Suggested values: ScaleStep ∈ {‘auto’, 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
  Restriction: ScaleStep ≥ 0

- **Optimization** (input_control) ..................................................... string(-array) ~ string
  Kind of optimization and optionally method used for generating the model.
  Default value: ‘auto’
  ‘point_reduction_high’, ‘pregeneration’, ‘no_pregeneration’}

- **Metric** (input_control) ............................................................. string ~ string
  Match metric.
  Default value: ‘use_polarity’
  List of values: Metric ∈ {‘use_polarity’, ‘ignore_global_polarity’, ‘ignore_local_polarity’,
  ‘ignore_color_polarity’}

- **Contrast** (input_control) ........................................................... number(-array) ~ integer / string
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum
  size of the object parts.
  Default value: ‘auto’
  Suggested values: Contrast ∈ {‘auto’, ‘auto_contrast’, ‘auto_contrast_hyst’, ‘auto_min_size’, 10, 20, 30,
  40, 60, 80, 100, 120, 140, 160}

- **MinContrast** (input_control) ..................................................... number ~ integer / string
  Minimum contrast of the objects in the search images.
  Default value: ‘auto’
  Suggested values: MinContrast ∈ {‘auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40}
  Restriction: MinContrast < Contrast

- **ModelID** (output_control) ......................................................... shape_model ~ handle
  Handle of the model.

---

If the parameters are valid, the operator `create_scaled_shape_model` returns the value 2
(H_MSG_TRUE). If necessary an exception is raised. If the parameters NumLevels and Contrast are chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

create_scaled_shape_model_xld ( Contours : : NumLevels,

    AngleStart, AngleExtent, AngleStep, ScaleMin, ScaleMax,

    ScaleStep, Optimization, Metric, MinContrast : ModelID )

Prepare an isotropically scaled shape model for matching from XLD contours.

The operator create_scaled_shape_model_xld creates an isotropically scaled shape model used for matching from the XLD contours passed in Contours. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator create_scaled_shape_model, which creates a shape model from a template image, the operator create_scaled_shape_model_xld creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_scaled_shape_model. The center of gravity of the smallest surrounding rectangle of the Contours that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with set_shape_model_origin. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and scales on each level. The model can be extended by clutter parameters with set_shape_model_clutter.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_scaled_shape_model_xld returns with an error message. If NumLevels is set to "auto", create_scaled_shape_model_xld determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_scaled_shape_model_xld determines a value for the number of pyramid levels that
is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in `find_scaled_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_scaled_shape_model` may increase. In these cases, the number of pyramid levels should be selected manually.

**AngleStart, AngleExtent and AngleStep:** The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the object can occur in the image during the search. Note that the object can only be found in this range of angles by `find_scaled_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_scaled_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_scaled_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

**ScaleMin, ScaleMax and ScaleStep:** The parameters `ScaleMin` and `ScaleMax` determine the range of possible scales (sizes) of the object. A scale of 1 corresponds to the original size of the model. The parameter `ScaleStep` determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the scales in `find_scaled_shape_model`. Like `AngleStep`, `ScaleStep` should be chosen based on the size of the object. If the range of scales is not an integer multiple of `ScaleStep`, `ScaleStep` is modified accordingly. To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_scaled_shape_model`, the range of possible scales is modified as follows: If there is no positive integer value n such that `ScaleMin` plus n times `ScaleStep` is exactly 1.0, `ScaleMin` is decreased by up to `ScaleStep` and `ScaleMax` is increased such that the range of possible scales is increased by `ScaleStep`.

**Optimization:** For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from 'none'. If `Optimization` = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_scaled_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to 'auto', `create_scaled_shape_model_xld` automatically determines the reduction of the number of model points.

**Metric:** The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric` = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric` = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_scaled_shape_model` will increase slightly in this case.

Note that the metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all `Contours` provide the attribute 'edge_direction', which defines the polarity of the edges. This attribute is available for contours created, e.g., with `edges_sub_pix` with the parameter `Method` set to, e.g., 'canny'. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

If `Metric` = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_scaled_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_scaled_shape_model_xld`, and to match them simultaneously with `find_scaled_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).
18.5. SHAPE-BASED

If Metric = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of find_scaled_shape_model can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for Metric = 'ignore_color_polarity' the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics (use_polarity and ignore_global_polarity) can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. For more information about contour attributes like 'edge_direction' see get_contour_attrib_xld. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

MinContrast: With MinContrast, it can be determined which contrast the object edges must at least have in the recognition performed by find_scaled_shape_model. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast must be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast must be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_scaled_shape_model.

Complete pregeneration of the model

Optionally, a second value can be passed in Optimization. This value determines whether the model is pre-generated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models',...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, find_scaled_shape_model typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if AngleStep or ScaleStep are too small or AngleExtent or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep or ScaleStep must be enlarged or AngleExtent or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_scaled_shape_model.AngleStep ≥ 1° and ScaleStep ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' or ScaleStep = 'auto' is selected, create_scaled_shape_model_xld automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using get_shape_model_params.

If a complete prepregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_scaled_shape_model. Because of this, the recognition of the model might require slightly more time.
Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

**Attention**
The XLD contours passed in **Contours** should have been scaled to approximately the average size of the object in the search images. This means that the product $\text{ScaleMin} \times \text{ScaleMax}$ should be approximately equal to 1.

Note that, in contrast to the operator **create_scaled_shape_model**, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling **create_scaled_shape_model_xld** with the operator **select_contours_xld**.

18.5. SHAPE-BASED

MinContrast (input_control) ......................................................... number => integer
Minimum contrast of the objects in the search images.
Default value: 5
Suggested values: MinContrast ∈ {1, 2, 3, 5, 7, 10, 20, 30, 40}
ModelID (output_control) ...................................................... shape_model => handle
Handle of the model.

Result
If the parameters are valid, the operator create_scaled_shape_model_xld returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter NumLevels is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Module

create_shape_model ( Template : : NumLevels, AngleStart,
AngleExtent, AngleStep, Optimization, Metric, Contrast,
MinContrast : : ModelID )

Prepare a shape model for matching.
The operator create_shape_model prepares a template, which is passed in the image Template, as a shape model used for matching. The ROI of the model is passed as the domain of Template.
The output parameter ModelID is a handle for this model, which is used in subsequent calls to find_shape_model. The center of gravity of the domain (region) of the model image Template is used as the origin (reference point) of the model. A different origin can be set with set_shape_model_origin.
The model is generated using multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations on each level. The model can be extended by clutter parameters with set_shape_model_clutter.

Input parameters in detail
NumLevels: The number of pyramid levels is determined with the parameter NumLevels. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, NumLevels must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of inspect_shape_model. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_shape_model returns with an error message.
If `NumLevels` is set to ‘auto’ (or 0 for backwards compatibility), `create_shape_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_shape_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_shape_model` may increase. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

**AngleStart, AngleExtent and AngleStep:** The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

**Optimization:** For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from ‘none’. If `Optimization` = ‘none’, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to ‘auto’, `create_shape_model` automatically determines the reduction of the number of model points.

**Metric:** The parameter `Metric` determines the conditions under which the model is recognized in the image.

- If `Metric` = ‘use_polarity’, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.
- If `Metric` = ‘ignore_global_polarity’, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_shape_model` will increase slightly in this case.
- If `Metric` = ‘ignore_local_polarity’, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_shape_model`, and to match them simultaneously with `find_shape_model`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

- If `Metric` = ‘ignore_color_polarity’, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_shape_model` can also increase significantly. The metric ‘ignore_color_polarity’ can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as ‘ignore_local_polarity’. It should be noted that for `Metric` = ‘ignore_color_polarity’ the number of channels in the model creation with `create_shape_model` and in the search with `find_shape_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

**Contrast:** The parameter `Contrast` determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of
the object. **Contrast** should be chosen such that only the significant features of the template are used for the model. **Contrast** can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, **Contrast** can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in **Contrast**. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with `inspect_shape_model`. If **Contrast** is set to *'auto'*`, `create_shape_model` determines the three above described values automatically. only the contrast (*'auto_contrast'*) , the hysteresis thresholds (*'auto_contrast_hyst'*) , or the minimum size (*'auto_min_size'*) can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, [*'auto_contrast','auto_contrast_hyst'*] is passed, both the contrast and the minimum size are determined automatically. If [*'auto_min_size',20,30*] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_shape_model_params` and subsequently verified using `inspect_shape_model` before calling `create_shape_model`. Note that MinContrast influences the automatic contrast estimation, and hence also the estimation of the minimum size.

**MinContrast:** With **MinContrast**, it can be determined which contrast the model must at least have in the recognition performed by `find_shape_model`. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, **MinContrast** should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to *'ignore_color_polarity'* (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine **MinContrast**. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image **MinContrast** should be set to 17. Obviously, **MinContrast** must be smaller than **Contrast**. If the model should be recognized in very low contrast images, **MinContrast** must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, **MinContrast** should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_shape_model`.

If **MinContrast** is set to *'auto'*`, the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using `get_shape_model_params`.

**Complete pregeneration of the model**

Optionally, a second value can be passed in **Optimization**. This value determines whether the model is pre-generated completely or not. To do so, the second value of **Optimization** must be set to either *'pregeneration'* or *'no_pregeneration'*. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models',...)` is used. With the default value (*'pregenerate_shape_models' = 'false'*), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for **MinScore** than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

HALCON 20.11.0.0
If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if AngleStep is too small or AngleExtent too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep must be enlarged or AngleExtent must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_shape_model, AngleStep ≥ 1 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = ‘auto’ (or 0 for backwards compatibility) is selected, create_shape_model automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_shape_model. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

---

**Parameters**

- **Template** (input_object) ................................. (multichannel-)image DISABLED object : byte / uint2
  
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) ................................. integer DISABLED integer / string
  
  Maximum number of pyramid levels.
  
  **Default value:** ‘auto’
  
  **List of values:** NumLevels ∈ {‘auto’, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) ............................... angle.rad DISABLED real
  
  Smallest rotation of the pattern.
  
  **Default value:** -0.39
  
  **Suggested values:** AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

- **AngleExtent** (input_control) ............................. angle.rad DISABLED real
  
  Extent of the rotation angles.
  
  **Default value:** 0.79
  
  **Suggested values:** AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}
  
  **Restriction:** AngleExtent ≥ 0

- **AngleStep** (input_control) ................................. angle.rad DISABLED real / string
  
  Step length of the angles (resolution).
  
  **Default value:** ‘auto’
  
  **Suggested values:** AngleStep ∈ {‘auto’, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
  
  **Restriction:** AngleStep ≥ 0 & & AngleStep <= pi / 16

- **Optimization** (input_control) ........................... string(-array) DISABLED string
  
  Kind of optimization and optionally method used for generating the model.
  
  **Default value:** ‘auto’
  
  **List of values:** Optimization ∈ {‘auto’, ‘none’, ‘point_reduction_low’, ‘point_reduction_medium’, ‘point_reduction_high’, ’pregeneration’, ’no_pregeneration’}

- **Metric** (input_control) ................................. string DISABLED string
  
  Match metric.
  
  **Default value:** ‘use_polarity’
  
  **List of values:** Metric ∈ {‘use_polarity’, ‘ignore_global_polarity’, ‘ignore_local_polarity’, ‘ignore_color_polarity’}

- **Contrast** (input_control) ................................. number(-array) DISABLED integer / string
  
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
  
  **Default value:** ‘auto’
  
  **Suggested values:** Contrast ∈ {‘auto’, ‘auto_contrast’, ‘auto_contrast_hyst’, ‘auto_min_size’, 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
18.5. SHAPE-BASED

- **MinContrast** (input_control) ....................................................... number \(\sim\) integer / string
  Minimum contrast of the objects in the search images.
  **Default value:** ‘auto’
  **Suggested values:** MinContrast \(\in\) \{'auto’, 1, 2, 3, 5, 7, 10, 20, 30, 40}.
  **Restriction:** MinContrast < Contrast

- **ModelID** (output_control) ........................................................... shape_model \(\sim\) handle
  Handle of the model.

---

**Result**

If the parameters are valid, the operator `create_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, the error 8510 is raised.

---

Matching

---

**create_shape_model_xld** ( Contours : : NumLevels, AngleStart,
   AngleExtent, AngleStep, Optimization, Metric,
   MinContrast : : ModelID )

Prepare a shape model for matching from XLD contours.

The operator `create_shape_model_xld` creates a shape model used for matching from the XLD contours passed in `Contours`. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator `create_shape_model`, which creates a shape model from a template image, the operator `create_shape_model_xld` creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_shape_model`. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

**Input parameters in detail**

- **NumLevels**: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number...
of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, create_shape_model_xld returns with an error message.

If NumLevels is set to 'auto', create_shape_model_xld determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using get_shape_model_params. In rare cases, it might happen that create_shape_model_xld determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for MinScore or Greediness in find_shape_model in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in find_shape_model may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent and AngleStep: The parameters AngleStart and AngleExtent determine the range of possible rotations, in which the object can occur in the image during the search. Note that the object can only be found in this range of angles by find_shape_model. The parameter AngleStep determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in find_shape_model, this parameter specifies the accuracy that is achievable for the angles in find_shape_model. AngleStep should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence AngleStep should be chosen larger for smaller models. If AngleExtent is not an integer multiple of AngleStep, AngleStep is modified accordingly.

To ensure that for model instances without rotation angle values of exactly 0.0 are returned by find_shape_model, the range of possible rotations is modified as follows: If there is no positive integer value n such that AngleStart plus n times AngleStep is exactly 0.0, AngleStart is decreased by up to AngleStep and AngleExtent is increased by AngleStep.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting Optimization to a value different from 'none'. If Optimization = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of Optimization. If the number of points is reduced, it may be necessary in find_shape_model to set the parameter Greediness to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If Optimization is set to 'auto', create_shape_model_xld automatically determines the reduction of the number of model points.

Metric: The parameter Metric determines the conditions under which the model is recognized in the image.

If Metric = 'use_polarity', the object in the image and the model have to have the same brightness. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_shape_model will increase slightly in this case.

Note that the metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. This attribute is available for contours created, e.g., with edges_sub_pix with the parameter Method set to, e.g., 'canny'. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

If Metric = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of find_shape_model increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with create_shape_model_xld, and to match them simultaneously with find_shape_models.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If Metric = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of find_shape_model can also increase significantly. The metric 'ignore_color_polarity' can be used
for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for Metric = 'ignore_color_polarity' the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions. Note that the first two metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all Contours provide the attribute 'edge_direction', which defines the polarity of the edges. For more information about contour attributes like 'edge_direction' see get_contour_attrib_xld. Otherwise, these two metrics can be selected with the operator set_shape_model_metric, which determines the polarity of the edges from an image.

MinContrast: With MinContrast, it can be determined which contrast the object edges must at least have in the recognition performed by find_shape_model. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the model and the search images, and if the parameter Metric is set to 'ignore_color_polarity' (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image MinContrast should be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by find_shape_model.

Complete pregeneration of the model

Optionally, a second value can be passed in Optimization. This value determines whether the model is pre-generated completely or not. To do so, the second value of Optimization must be set to either 'pregeneration' or 'no_pregeneration'. If the second value is not used (i.e., if only one value is passed), the mode that is set with set_system('pregenerate_shape_models',...) is used. With the default value ('pregenerate_shape_models' = 'false'), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, find_shape_model typically returns slightly lower scores, which may require setting a slightly lower value for MinScore than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment. If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if AngleStep is too small or AngleExtent too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either AngleStep must be enlarged or AngleExtent must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by find_shape_model, AngleStep ≥ 1 can be selected for models of a diameter smaller than about 200 pixels.

If AngleStep = 'auto' is selected, create_shape_model_xld automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using get_shape_model_params.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in find_shape_model. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

Note that, in contrast to the operator create_shape_model, it is not possible to specify a minimum size of
the model components. To avoid small model components in the shape model, short contours can be eliminated before calling `create_shape_model_xld` with the operator `select_contours_xld`.

**Parameters**

- **Contours** (input_object) → object
  Input contours that will be used to create the model.

- **NumLevels** (input_control) → integer
  Maximum number of pyramid levels.
  **Default value:** ‘auto’
  **List of values:** `NumLevels ∈ {‘auto’, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}`

- **AngleStart** (input_control) → real
  Smallest rotation of the pattern.
  **Default value:** -0.39
  **Suggested values:** `AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}`

- **AngleExtent** (input_control) → real
  Extent of the rotation angles.
  **Default value:** 0.79
  **Suggested values:** `AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}`
  **Restriction:** `AngleExtent >= 0`

- **AngleStep** (input_control) → real / string
  Step length of the angles (resolution).
  **Default value:** ‘auto’
  **Suggested values:** `AngleStep ∈ {‘auto’, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}`
  **Restriction:** `AngleStep > 0` && `AngleStep <= pi / 16`

- **Optimization** (input_control) → string(-array)
  Kind of optimization and optionally method used for generating the model.
  **Default value:** ‘auto’

- **Metric** (input_control) → string
  Match metric.
  **Default value:** ‘ignore_local_polarity’
  **List of values:** `Metric ∈ {‘use_polarity’, ‘ignore_global_polarity’, ‘ignore_local_polarity’, ‘ignore_color_polarity’}`

- **MinContrast** (input_control) → integer
  Minimum contrast of the objects in the search images.
  **Default value:** 5
  **Suggested values:** `MinContrast ∈ {1, 2, 3, 5, 7, 10, 20, 30, 40}`

- **ModelID** (output_control) → shape_model
  Handle of the model.

**Result**

If the parameters are valid, the operator `create_shape_model_xld` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

deserialize_shape_model ( : :SerializedItemHandle : ModelID )

Deserialize a serialized shape model.

deserialize_shape_model deserializes a shape model, that was serialized by 
serialize_shape_model (see fwrite_serialized_item for an introduction of the basic prin-
ciple of serialization). The serialized shape model is defined by the handle SerializedItemHandle. The
deserialized values are stored in an automatically created shape model with the handle ModelID.

________________________ Parameters

▷ SerializedItemHandle (input_control) ..................serialized_item ↦ handle
Handle of the serialized item.

▷ ModelID (output_control) ..................shape_model ↦ handle
Handle of the model.

________________________ Result

If the parameters are valid, the operator deserialize_shape_model returns the value 2 (H_MSG_TRUE). If
necessary, an exception is raised.

________________________ Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

determine_shape_model_params ( Template : : NumLevels,
  AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization,
  Metric, Contrast, MinContrast, Parameters : ParameterName,
  ParameterValue )

Determine the parameters of a shape model.

determine_shape_model_params determines certain parameters of a shape model automatically from
the model image Template. The parameters to be determined can be specified with Parameters.
create_shape_model, create_scaled_shape_model, or create_aniso_shape_model is set to 'auto': the number of pyramid levels (Parameters = 'num_levels'), the angle step length (Parameters = 'angle_step'), the scale step length (Parameters = 'scale_step' for isotropic scaling and 'scale_r_step' and/or 'scale_c_step' for anisotropic scaling), the kind of optimization (Parameters = 'optimization'), the threshold (Parameters = 'contrast') or the hysteresis thresholds (Parameters = 'contrast_hyst') for the contrast, the minimum size of the object parts (Parameters = 'min_size'), and the minimum contrast (Parameters = 'min_contrast'). By passing a tuple of the above values in Parameters, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed. In this case both hysteresis thresholds are determined, i.e., the operator behaves like passing 'contrast_hyst' instead of 'contrast'.

determine_shape_model_params is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in ParameterName and ParameterValue. The parameter names in ParameterName are identical to the names in Parameters, where, of course, the value 'all' is replaced by the actual parameter names. An exception is the parameter 'contrast_hyst', for which the two values 'contrast_low' and 'contrast_high' are returned.

The remaining parameters (NumLevels, AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization, Metric, Contrast, and MinContrast) have the same meaning as in create_shape_model, create_scaled_shape_model, and create_aniso_shape_model. The description of these parameters can be looked up with these operators. These parameters are used by determine_shape_model_params to calculate the parameters to be determined in the same manner as in create_shape_model, create_scaled_shape_model, and create_aniso_shape_model. It should be noted that if the parameters of a shape model with isotropic scaling should be determined, i.e., if Parameters contains 'scale_step' either explicitly or implicitly via 'all', the parameters ScaleMin and ScaleMax must contain one value each. If the parameters of a shape model with anisotropic scaling should be determined, i.e., if Parameters contains 'scale_r_step' or 'scale_c_step' either explicitly or implicitly, the parameters ScaleMin and ScaleMax must contain two values each. In this case, the first value of the respective parameter refers to the scaling in the row direction, while the second value refers to the scaling in the column direction.

Note that in determine_shape_model_params some parameters appear that can also be determined automatically (NumLevels, Optimization, Contrast, MinContrast). If these parameters should not be determined automatically, i.e., their name is not passed in Parameters, the corresponding parameters must contain valid values and must not be set to 'auto'. In contrast, if these parameters are to be determined automatically, their values are treated in the following way: If the optimization or the (hysteresis) contrast is to be determined automatically, i.e., Parameters contains the value 'optimization' or 'contrast' ('contrast_hyst'), the values passed in Optimization and Contrast are ignored. In contrast, if the maximum number of pyramid levels or the minimum contrast is to be determined automatically, i.e., Parameters contains the value 'num_levels' or 'min_contrast', you can let HALCON determine suitable values and at the same time specify an upper or lower boundary, respectively:

If the maximum number of pyramid levels should be specified in advance, NumLevels can be set to the particular value. If in this case Parameters contains the value 'num_levels', the computed number of pyramid levels is at most NumLevels. If NumLevels is set to 'auto' (or 0 for backwards compatibility), the number of pyramid levels is determined without restrictions as large as possible.

If the minimum contrast should be specified in advance, MinContrast can be set to the particular value. If in this case Parameters contains the value 'min_contrast', the computed minimum contrast is at least MinContrast. If MinContrast is set to 'auto', the minimum contrast is determined without restrictions.

In some cases, the maximum number of pyramid levels that is returned by determine_shape_model_params is higher than the number of levels that are actually used in the shape model. The latter can be queried by using get_shape_model_params after creating the model. This might happen if the model is created by using create_scaled_shape_model or create_aniso_shape_model and ScaleMin, ScaleRMin, or ScaleCMin is below 1.0.
18.5. SHAPE-BASED

Parameters

- **Template** (input_object) ......................... (multichannel-)image ~ object : byte / uint2
  Input image whose domain will be used to create the model.

- **NumLevels** (input_control) ..................... integer ~ integer / string
  Maximum number of pyramid levels.
  Default value: 'auto'
  List of values: NumLevels ∈ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- **AngleStart** (input_control) .................. angle.rad ~ real
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

- **AngleExtent** (input_control) ................. angle.rad ~ real
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39}
  Restriction: AngleExtent >= 0

- **ScaleMin** (input_control) ..................... number(-array) ~ real
  Minimum scale of the model.
  Default value: 0.9
  Suggested values: ScaleMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: ScaleMin > 0

- **ScaleMax** (input_control) ..................... number(-array) ~ real
  Maximum scale of the model.
  Default value: 1.1
  Suggested values: ScaleMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
  Restriction: ScaleMax >= ScaleMin

- **Optimization** (input_control) ............... string ~ string
  Kind of optimization.
  Default value: 'auto'
  List of values: Optimization ∈ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}

- **Metric** (input_control) ....................... string ~ string
  Match metric.
  Default value: 'use_polarity'
  List of values: Metric ∈ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}

- **Contrast** (input_control) ..................... number(-array) ~ integer / string
  Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
  Default value: 'auto'
  Suggested values: Contrast ∈ {'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}

- **MinContrast** (input_control) ................. integer ~ integer / string
  Minimum contrast of the objects in the search images.
  Default value: 'auto'
  Suggested values: MinContrast ∈ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
  Restriction: MinContrast < Contrast

- **Parameters** (input_control) .................. string(-array) ~ string
  Parameters to be determined automatically.
  Default value: 'all'
  List of values: Parameters ∈ {'all', 'num_levels', 'angle_step', 'scale_step', 'scale_r_step', 'scale_c_step', 'optimization', 'contrast', 'contrast_hyst', 'min_size', 'min_contrast'}

- **ParameterName** (output_control) ............. string-array ~ string
  Name of the automatically determined parameter.

- **ParameterValue** (output_control) .......... number-array ~ real / integer
  Value of the automatically determined parameter.
Result

If the parameters are valid, the operator determine_shape_model_params returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters NumLevels and Contrast are chosen such that the model contains too few points, or the input image does not contain a sufficient number of significant features, the error 8510 is raised.

Execution Information

find_aniso_shape_model { Image : : ModelID, AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, ScaleR, ScaleC, Score }

Find the best matches of an anisotropically scaled shape model in an image.

The operator find_aniso_shape_model finds the best NumMatches instances of the anisotropically scaled shape model ModelID in the input image Image. The model must have been created previously by calling create_aniso_shape_model or read_shape_model.

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in Row, Column, Angle, ScaleR, and ScaleC. Additionally, the score of each found instance is returned in Score.

Input parameters in detail

The image and its domain: The domain of the image Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with create_aniso_shape_model. A different origin set with set_shape_model_origin is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with set_system('border_shape_models','true') for all models or with set_shape_model_param(ModelID, 'border_shape_models','true') for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than MinScore. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., dilation_circle.

AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax: The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. The parameters
The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

In case that the shape model has been extended by clutter parameters with set_shape_model_clutter and thus ‘use_clutter’ is enabled, MinScore expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

In case that the shape model has been extended by clutter parameters with set_shape_model_clutter and thus ‘use_clutter’ is enabled, MinScore expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime.

NumMatches: The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using set_shape_model_clutter, NumMatches also considers the second value passed in MinScore: If more than NumMatches instances with a score greater than the first entry of MinScore and a clutter value smaller than the second entry of MinScore are found in the image, only the best NumMatches instances with respect to clutter are returned. Still, MinScore takes precedence over NumMatches and NumMatches must be set to 0 if all model instances fulfilling the conditions imposed by MinScore should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

SubPixel: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to ‘none’ (or ‘false’ for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with create_aniso_shape_model. If SubPixel is set to ‘interpolation’ (or ‘true’) the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high
enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to ‘interpolation’, this mode requires additional computation time. The different modes for least-squares adjustment (‘least_squares’, ‘least_squares_high’, and ‘least_squares_very_high’) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to ‘interpolation’. If least-squares adjustment is desired, ‘least_squares’ should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value ‘max_deformation’ followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value ‘max_deformation 2’ must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value ‘max_deformation 0’ corresponds to a search without allowing deformations, i.e., the behavior is the same as if no ‘max_deformation’ is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if ‘max_deformation’ and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either ‘max_deformation’ or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if ‘least_squares’, ‘least_squares_high’, or ‘least_squares_very_high’ (see above) is chosen for the subpixel extraction (in comparison to ‘none’ or ‘interpolation’). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

NumLevels: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_aniso_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_aniso_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_aniso_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_aniso_shape_model. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least ‘least_squares’. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or
Using the operator `set_shape_model_param`

Specifying a timeout

To display the results found by shape-based matching, we highly recommend the usage of the procedure `timeout`.

Transformations have to be freed after a timeout occurs, the runtime of a significant amount of time to free cached transformations if the shape model is not pregenerated. As this is ScaleRMin by `find_aniso_shape_model`

The score of each found instance is returned in `Score`

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. The coordinates `Row` and `Column` are related to the position of the origin of the shape model in the search image. However, `Row` and `Column` do not exactly correspond to this position. Instead, `find_aniso_shape_model` returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see `affine_trans_pixel`). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin can be set with `set_shape_model_origin`.

The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, `Score = [0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

Specifying a timeout

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_aniso_shape_model`. If `find_aniso_shape_model` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling ranges specified by `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax`, `find_aniso_shape_model` needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of `find_aniso_shape_model` exceeds the value of the specified 'timeout' by this time.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`. 

HALCON 20.11.0.0
Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- **Image** (input_object) \((\text{multichannel-})\text{image} \sim \text{object} : \text{byte} / \text{uint2} \)
  Input image in which the model should be found.
- **ModelID** (input_control) \(\sim \text{shape_model} \sim \text{handle} \)
  Handle of the model.
- **AngleStart** (input_control) \(\sim \text{angle.rad} \sim \text{real} \)
  Smallest rotation of the model.
  Default value: -0.39
  Suggested values: \(\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)
- **AngleExtent** (input_control) \(\sim \text{angle.rad} \sim \text{real} \)
  Extent of the rotation angles.
  Default value: 0.79
  Suggested values: \(\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)
  Restriction: \(\text{AngleExtent} \geq 0\)
- **ScaleRMin** (input_control) \(\sim \text{number} \sim \text{real} \)
  Minimum scale of the model in the row direction.
  Default value: 0.9
  Suggested values: \(\text{ScaleRMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Restriction: \(\text{ScaleRMin} > 0\)
- **ScaleRMax** (input_control) \(\sim \text{number} \sim \text{real} \)
  Maximum scale of the model in the row direction.
  Default value: 1.1
  Suggested values: \(\text{ScaleRMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4\}\)
  Restriction: \(\text{ScaleRMax} \geq \text{ScaleRMin}\)
- **ScaleCMin** (input_control) \(\sim \text{number} \sim \text{real} \)
  Minimum scale of the model in the column direction.
  Default value: 0.9
  Suggested values: \(\text{ScaleCMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Restriction: \(\text{ScaleCMin} > 0\)
- **ScaleCMax** (input_control) \(\sim \text{number} \sim \text{real} \)
  Maximum scale of the model in the column direction.
  Default value: 1.1
  Suggested values: \(\text{ScaleCMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4\}\)
  Restriction: \(\text{ScaleCMax} \geq \text{ScaleCMin}\)
- **MinScore** (input_control) \(\sim \text{real(-array)} \sim \text{real} \)
  Minimum score of the instances of the model to be found.
  Default value: 0.5
  Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05
- **NumMatches** (input_control) \(\sim \text{integer} \sim \text{integer} \)
  Number of instances of the model to be found (or 0 for all matches).
  Default value: 1
  Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)
- **MaxOverlap** (input_control) \(\sim \text{real} \sim \text{real} \)
  Maximum overlap of the instances of the model to be found.
  Default value: 0.5
  Suggested values: \(\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
  Typical range of values: \(0 \leq \text{MaxOverlap} \leq 1\)
  Minimum increment: 0.01
  Recommended increment: 0.05
18.5. SHAPE-BASED

- **SubPixel** (input_control) .................................................. string(-array) \(\sim\) string
  Subpixel accuracy if not equal to `'none'`.
  **Default value:** `'least_squares'`
  **Suggested values:** SubPixel \(\in\) {`'none'`, `'interpolation'`, `'least_squares'`, `'least_squares_high'`, `'least_squares_very_high'`, `'max_deformation 1'`, `'max_deformation 2'`, `'max_deformation 3'`, `'max_deformation 4'`, `'max_deformation 5'`, `'max_deformation 6'`}

- **NumLevels** (input_control) ............................................. integer(-array) \(\sim\) integer
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).
  **Default value:** 0
  **List of values:** NumLevels \(\in\) \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

- **Greediness** (input_control) .............................................. real \(\sim\) real
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
  **Default value:** 0.9
  **Suggested values:** Greediness \(\in\) \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}
  **Typical range of values:** \(0 \leq \text{Greediness} \leq 1\)
  **Minimum increment:** 0.01
  **Recommended increment:** 0.05

- **Row** (output_control) ................................................... point.y-array \(\sim\) real
  Row coordinate of the found instances of the model.

- **Column** (output_control) ............................................... point.x-array \(\sim\) real
  Column coordinate of the found instances of the model.

- **Angle** (output_control) ................................................ angle.rad-array \(\sim\) real
  Rotation angle of the found instances of the model.

- **ScaleR** (output_control) .............................................. number-array \(\sim\) real
  Scale of the found instances of the model in the row direction.

- **ScaleC** (output_control) .............................................. number-array \(\sim\) real
  Scale of the found instances of the model in the column direction.

- **Score** (output_control) ............................................... real-array \(\sim\) real
  Score of the found instances of the model.

---

**Example**

```halcon
create_aniso_shape_model (ImageReduced, 0, rad(-15), rad(30), 0, \ 0.9, 1.1, 0, 0.9, 1.1, 0, 'none', \ 'use_polarity', 30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_aniso_shape_model (SearchImage, ModelID, rad(-15), rad(30), \ 0.9, 1.1, 0.9, 1.1, 0.5, 1, 0.5, 'interpolation', \ 0, 0, Row, Column, Angle, ScaleR, ScaleC, Score)
```

---

**Result**

If the parameter values are correct, the operator `find_aniso_shape_model` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system` (`'no_object_result',<Result>`). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

HALCON 20.11.0.0
Match the best matches of multiple anisotropically scaled shape models.

The operator `find_aniso_shape_models` finds the best `NumMatches` instances of the anisotropically scaled shape models that are passed in `ModelIDs` in the input image `Image`. The models must have been created previously by calling `create_aniso_shape_model` or `read_shape_model`. In contrast to `find_aniso_shape_model`, multiple models can be searched in the same image in one call.

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. The score of each found instance is returned in `Score`. The type of the found instances of the models is returned in `Model`. For details see respective sections below.

Characteristics of the parameter semantics

Compared to `find_aniso_shape_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. `NumLevels` may also contain either two or twice the number of elements as `ModelIDs`. More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_aniso_shape_models` with multiple values for `ModelIDs`, `NumMatches` and `MaxOverlap` has the same effect as multiple independent calls to `find_aniso_shape_model` with the respective parameters. However, a single call to `find_aniso_shape_models` is considerably more efficient.

Input parameters in detail

The `image and its domain` The domain of the `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below \(2^{\text{NumLevels}} - 1\). This behavior can be changed with `set_system('border_shape_models', 'true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models', 'true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further,
that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by \(2^{\text{NumLevels}-1}\) using, e.g., \texttt{dilation\_circle}.

As usual, the domain of the input \texttt{Image} is used to restrict the search space for the reference point of the models \texttt{ModelIDs}. Consistent with the above semantics, the input \texttt{Image} can therefore contain a single image object or an image object tuple containing multiple image objects. If \texttt{Image} contains a single image object, its domain is used as the region of interest for all models in \texttt{ModelIDs}. If \texttt{Image} contains multiple image objects, each domain is used as the region of interest for the corresponding model in \texttt{ModelIDs}. In this case, the images have to be identical except for their domains, i.e., \texttt{Image} cannot be constructed in an arbitrary manner using \texttt{concat\_obj}, but must be created from the same image using \texttt{add\_channels} or equivalent calls. If this is not the case, an error message is returned.

**AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax:** The parameters \texttt{AngleStart} and \texttt{AngleExtent} determine the range of rotations for which the model is searched. The parameters \texttt{ScaleRMin}, \texttt{ScaleRMax}, \texttt{ScaleCMin}, and \texttt{ScaleCMax} determine the range of scales in the row and column directions for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with \texttt{create\_aniso\_shape\_model}. In particular, this means that the angle ranges of the model and the search must overlap.

If in \texttt{ModelIDs} a model is passed that was created by using \texttt{create\_shape\_model} or \texttt{create\_scaled\_shape\_model} then the model is searched with an isotropic scaling of 1.0 or with an isotropic scaling within the range from \texttt{ScaleRMin} to \texttt{ScaleRMax}, respectively. In this case, for \texttt{ScaleR} and \texttt{ScaleC} identical values are returned.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. \texttt{AngleStart} and \texttt{AngleExtent} as well as \texttt{ScaleRMin}/\texttt{ScaleCMin} and \texttt{ScaleRMax}/\texttt{ScaleCMax} are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level.

For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

**MinScore:** The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger \texttt{MinScore} is chosen, the faster the search is. If the model can be expected never to be occluded in the images, \texttt{MinScore} may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below \texttt{MinScore} are found.

If a single value is passed in \texttt{MinScore}, this value is applied to found instances of all models. If, on the other hand, \texttt{MinScore} contains multiple values, the values are applied separately for the respective model.

In case that the shape models have been extended by clutter parameters with \texttt{set\_shape\_model\_clutter} and thus \texttt{'use\_clutter'} is enabled, \texttt{MinScore} expects for each minimum score an additional value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for \texttt{'use\_clutter'}.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, \texttt{MinScore} must contain twice the number of elements as \texttt{ModelIDs}. In this case, the minimum score and the maximum clutter must be specified interleaved in \texttt{MinScore}. If, for example, two models are specified in \texttt{ModelIDs}, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, \texttt{MinScore} = [0.9, 0.1, 0.8, 0.2] must be selected.

**NumMatches:** The maximum number of instances to be found can be determined with \texttt{NumMatches}. If more than \texttt{NumMatches} instances with a score greater than \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances are returned. If fewer than \texttt{NumMatches} are found, only that number is returned, i.e., the parameter \texttt{MinScore} takes precedence over \texttt{NumMatches}. If all model instances exceeding \texttt{MinScore} in the image should be found, \texttt{NumMatches} must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on \texttt{NumMatches}. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for \texttt{NumMatches} set to 1 might be different from the match with the highest score returned when setting \texttt{NumMatches} to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise \texttt{NumMatches}, and then select the match with the highest score.
In case that the shape models have been extended by clutter parameters using \texttt{set_shape_model_clutter}, \texttt{NumMatches} also considers the second value passed in \texttt{MinScore}: If more than \texttt{NumMatches} instances with a score greater than the first entry of \texttt{MinScore} and a clutter value smaller than the second entry of \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances with respect to clutter are returned. Still, \texttt{MinScore} takes precedence over \texttt{NumMatches} and \texttt{NumMatches} must be set to 0 if all model instances fulfilling the conditions imposed by \texttt{MinScore} should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0.

If \texttt{NumMatches} contains one element, \texttt{find_aniso_shape_models} returns the best \texttt{NumMatches} instances of the model irrespective of the type of the model. If, for example, two models are passed in \texttt{ModelIDs} and \texttt{NumMatches} = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, \texttt{NumMatches} contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in \texttt{NumMatches}. If, for example, \texttt{NumMatches} = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.

\textbf{MaxOverlap:} If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter \texttt{MaxOverlap} determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than \texttt{MaxOverlap} only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see \texttt{smallest_rectangle2}) of the found instances. If \texttt{MaxOverlap} = 0, the found instances may not overlap at all, while for \texttt{MaxOverlap} = 1 all instances are returned.

If a single value is passed in \texttt{MaxOverlap}, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in \texttt{MaxOverlap}, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

\textbf{SubPixel:} The parameter \texttt{SubPixel} determines whether the instances should be extracted with subpixel accuracy. If \texttt{SubPixel} is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with \texttt{create_aniso_shape_model}. If \texttt{SubPixel} is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment (‘least_squares’, ‘least_squares_high’, and ‘least_squares_very_high’) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, \texttt{SubPixel} should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter \texttt{SubPixel}. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in \texttt{SubPixel} in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if
clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max deformation' and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max deformation' or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares_very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in ModelIDs exactly one value for the subpixel extraction must be passed in SubPixel. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in ModelIDs and for the first model the subpixel extraction is set to 'interpolation' and no object deformations are allowed and for the second model the subpixel extraction is set to 'least_squares' and a maximum object deformation of 3 pixels is allowed, then the tuple ['interpolation', 'least_squares', 'max_deformation 3'] must be passed in SubPixel. Alternatively, the equivalent tuple ['interpolation', 'least_squares', 'max_deformation 0', 'least_squares', 'max_deformation 3'] may be passed.

**NumLevels**: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_aniso_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_aniso_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_aniso_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_aniso_shape_models. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least 'least_squares'. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, NumLevels must contain twice the number of elements as ModelIDs. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in NumLevels. If, for example, two models are specified in ModelIDs, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, NumLevels = [5, 2, 4, 1] must be selected. If exactly two models are specified in ModelIDs, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in NumLevels is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found,
depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in \texttt{NumLevels}. If, e.g., \texttt{NumLevels} is set to \$\{5,2,4,-1\}$, the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to \$-1\$. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If a model was adapted with \texttt{adapt_shape_model_high_noise} the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing explicitly the lowest pyramid level as described above.

**Greediness:** The parameter \texttt{Greediness} determines how “greedily” the search should be carried out. If \texttt{Greediness} $= 0$, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If \texttt{Greediness} $= 1$, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For \texttt{Greediness} $= 1$, the maximum search speed is achieved. In almost all cases, the shape model will always be found for \texttt{Greediness} $= 0, 0.9$.

**Output parameters in detail**

\texttt{Row, Column, Angle, ScaleR, ScaleC}: The position, rotation, and scale in the row and column direction of the found instances of the model are returned in \texttt{Row, Column, Angle, ScaleR, and ScaleC}. The coordinates \texttt{Row} and \texttt{Column} are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with \texttt{create_aniso_shape_model}. A different origin can be set with \texttt{set_shape_model_origin}.

Note that the coordinates \texttt{Row} and \texttt{Column} do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for \texttt{find_aniso_shape_model} shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure \texttt{dev_display_shape_matching_results} can be used.

\texttt{Score}: The score of each found instance is returned in \texttt{Score}. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using \texttt{set_shape_model_clutter}, following the above values \texttt{Score} also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, \texttt{Score} = \$[0.9, 0.8, 0.2, 0.1]$ is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

\texttt{Model}: The type of the found instances of the models is returned in \texttt{Model}. The elements of \texttt{Model} are indices into the tuple \texttt{ModelIDs}, i.e., they can contain values from 0 to \texttt{\{ModelIDs\} - 1}. Hence, a value of 0 in an element of \texttt{Model} corresponds to an instance of the first model in \texttt{ModelIDs}.

**Specifying a timeout**

Using the operator \texttt{set_shape_model_param} you can specify a ‘timeout’ for \texttt{find_aniso_shape_models}. If the shape models referenced by \texttt{ModelIDs} hold different values for ‘timeout’, \texttt{find_aniso_shape_models} uses the smallest one. If \texttt{find_aniso_shape_models} reaches this ‘timeout’, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling ranges specified by \texttt{ScaleRMin, ScaleRMax, ScaleCMin} and \texttt{ScaleCMax}, \texttt{find_aniso_shape_models} needs a significant amount of time to free cached transformations if the shape model is not regenerated. As this transformations have to be freed after a timeout occurs, the runtime of \texttt{find_aniso_shape_models} exceeds the value of the specified ‘timeout’ by this time.

**MinContrast with multiple models**
Please note, that the different models that are given with the parameter `ModelIDs` should have been created with the same value of `MinContrast`. If they were created with different values for `MinContrast`, `find_aniso_shape_models` will use the smallest of these values.

**Visualization of the results**

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

**Further Information**

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter `Transformations / 2D Transformations`.

---

**Parameters**

- `Image` *(input_object)*: *(multichannel-)image(-array) ~ object: byte / uint2*
  
  Input image in which the models should be found.

- `ModelIDs` *(input_control)*: *(shape_model(-array) ~ handle)*
  
  Handle of the models.

- `AngleStart` *(input_control)*: *(angle.rad(-array) ~ real)*
  
  Smallest rotation of the models.
  
  **Default value:** -0.39
  
  **Suggested values:** `AngleStart ∈ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}`

- `AngleExtent` *(input_control)*: *(angle.rad(-array) ~ real)*
  
  Extent of the rotation angles.
  
  **Default value:** 0.79
  
  **Suggested values:** `AngleExtent ∈ {6.29, 3.14, 1.57, 0.79, 0.39, 0.0}`
  
  **Restriction:** `AngleExtent ≥ 0`

- `ScaleRMin` *(input_control)*: *(number(-array) ~ real)*
  
  Minimum scale of the models in the row direction.
  
  **Default value:** 0.9
  
  **Suggested values:** `ScaleRMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}`
  
  **Restriction:** `ScaleRMin > 0`

- `ScaleRMax` *(input_control)*: *(number(-array) ~ real)*
  
  Maximum scale of the models in the row direction.
  
  **Default value:** 1.1
  
  **Suggested values:** `ScaleRMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}`
  
  **Restriction:** `ScaleRMax ≥ ScaleRMin`

- `ScaleCMin` *(input_control)*: *(number(-array) ~ real)*
  
  Minimum scale of the models in the column direction.
  
  **Default value:** 0.9
  
  **Suggested values:** `ScaleCMin ∈ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}`
  
  **Restriction:** `ScaleCMin > 0`

- `ScaleCMax` *(input_control)*: *(number(-array) ~ real)*
  
  Maximum scale of the models in the column direction.
  
  **Default value:** 1.1
  
  **Suggested values:** `ScaleCMax ∈ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}`
  
  **Restriction:** `ScaleCMax ≥ ScaleCMin`

- `MinScore` *(input_control)*: *(real(-array) ~ real)*
  
  Minimum score of the instances of the models to be found.
  
  **Default value:** 0.5
  
  **Suggested values:** `MinScore ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}`
  
  **Typical range of values:** `0 ≤ MinScore ≤ 1`
  
  **Minimum increment:** 0.01
  
  **Recommended increment:** 0.05

- `NumMatches` *(input_control)*: *(integer(-array) ~ integer)*
  
  Number of instances of the models to be found (or 0 for all matches).
  
  **Default value:** 1
  
  **Suggested values:** `NumMatches ∈ {0, 1, 2, 3, 4, 5, 10, 20}`

### `find_scaled_shape_model`

```c
find_scaled_shape_model ( Image : : ModelID, AngleStart,
    AngleExtent, ScaleMin, ScaleMax, MinScore, NumMatches,
    MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column,
    Angle, Scale, Score )
```

Find the best matches of an isotropically scaled shape model in an image.

The operator `find_scaled_shape_model` finds the best `NumMatches` instances of the isotropically scaled shape model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_scaled_shape_model` or `read_shape_model`.

The position, rotation, and scale of the found instances of the model are returned in `Row`, `Column`, `Angle`, and `Scale`. The score of each found instance is returned in `Score`.

#### Input parameters in detail

**The image and its domain:** The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_scaled_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with `set_system('border_shape_models',true) for all models or with `set_shape_model_param(ModelID, 'border_shape_models',true) for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., `dilation_circle`.

HALCON 20.11.0.0
**AngleStart, AngleExtent, ScaleMin, ScaleMax:** The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. The parameters `ScaleMin` and `ScaleMax` determine the range of scales for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with `create_scaled_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` as well as `ScaleMin` and `ScaleMax` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level.

For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

**MinScore:** The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

In case that the shape model has been extended by clutter parameters with `set_shape_model_clutter` and thus "use_clutter" is enabled, `MinScore` expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime.

**NumMatches:** The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to $I$ might be different from the match with the highest score returned when setting `NumMatches` to 0 or $I > 1$. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter value smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

**MaxOverlap:** If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

**SubPixel:** The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with `create_scaled_shape_model`. If `SubPixel` is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode
The number of pyramid levels used during the search is determined with \texttt{NumLevels}. SHAPE-BASED

SubPixel but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value \texttt{max_deformation} followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value \texttt{max_deformation 2} must be passed in \texttt{SubPixel} in addition to the above described mode for the subpixel extraction, i.e., for example \texttt{[least_squares, max_deformation 2]}. Passing the value \texttt{max_deformation 0} corresponds to a search without allowing deformations, i.e., the behavior is the same as if no \texttt{max_deformation} is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if \texttt{max_deformation} and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either \texttt{max_deformation} or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if \texttt{least_squares}, \texttt{least_squares_high}, or \texttt{least_squares_very_high} (see above) is chosen for the subpixel extraction (in comparison to \texttt{none} or \texttt{interpolation}). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

**NumLevels:** The number of pyramid levels used during the search is determined with \texttt{NumLevels}. If necessary, the number of levels is clipped to the range given when the shape model was created with \texttt{create_scaled_shape_model}. If \texttt{NumLevels} is set to 0, the number of pyramid levels specified in \texttt{create_scaled_shape_model} is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, \texttt{create_scaled_shape_model} may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of \texttt{NumLevels} with \texttt{get_shape_model_params} and then use a slightly lower value in \texttt{find_scaled_shape_model}. This approach is often better regarding the speed and robustness of the matching.

Optionally, \texttt{NumLevels} can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of \texttt{[4,2]} for \texttt{NumLevels} means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, \texttt{SubPixel} should be set to at least \texttt{least_squares}. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable
pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in NumLevels. If, e.g., NumLevels is set to \([-4,-2]\), the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If the ModelID was adapted with adapt_shape_model_high_noise the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing two values to NumLevels and explicitly setting the lowest pyramid level.

**Greediness:** The parameter Greediness determines how “greedily” the search should be carried out. If Greediness = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If Greediness = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For Greediness = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for Greediness = 0.9.

**Output parameters in detail**

**Row, Column, Angle and Scale:** The position, rotation, and scale of the found instances of the model are returned in Row, Column, Angle, and Scale. The coordinates Row and Column are related to the position of the origin of the shape model in the search image. However, Row and Column do not exactly correspond to this position. Instead, find_scaled_shape_model returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see affine_trans_pixel). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with create_shape_model. A different origin can be set with set_shape_model_origin.

**Score:** The score of each found instance is returned in Score. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using set_shape_model_clutter, following the above values Score also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, Score = \([0.9, 0.8, 0.2, 0.1]\) is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Specifying a timeout**

Using the operator set_shape_model_param you can specify a ‘timeout’ for find_scaled_shape_model. If find_scaled_shape_model reaches this ‘timeout’, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling range specified by ScaleMin, and ScaleMax, find_scaled_shape_model needs a significant amount of time to free cached transformations if the shape model is not regenerated. As this transformations have to be freed after a timeout occurs, the runtime of find_scaled_shape_model exceeds the value of the specified ‘timeout’ by this time.

**Visualization of the results**

To display the results found by shape-based matching, we highly recommend the usage of the procedure dev_display_shape_matching_results.

**Further Information**

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.
18.5. SHAPE-BASED

**Parameters**

- **Image** (input_object)
  - (multichannel-)image \( \sim \) object : byte / uint2
  - Input image in which the model should be found.

- **ModelID** (input_control)
  - shape_model \( \sim \) handle
  - Handle of the model.

- **AngleStart** (input_control)
  - angle.rad \( \sim \) real
  - Smallest rotation of the model.
  - Default value: -0.39
  - Suggested values: \( \text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\} \)

- **AngleExtent** (input_control)
  - angle.rad \( \sim \) real
  - Extent of the rotation angles.
  - Default value: 0.78
  - Suggested values: \( \text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\} \)
  - Restriction: \( \text{AngleExtent} \geq 0 \)

- **ScaleMin** (input_control)
  - number \( \sim \) real
  - Minimum scale of the model.
  - Default value: 0.9
  - Suggested values: \( \text{ScaleMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  - Restriction: \( \text{ScaleMin} > 0 \)

- **ScaleMax** (input_control)
  - number \( \sim \) real
  - Maximum scale of the model.
  - Default value: 1.1
  - Suggested values: \( \text{ScaleMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\} \)
  - Restriction: \( \text{ScaleMax} \geq \text{ScaleMin} \)

- **MinScore** (input_control)
  - real(-array) \( \sim \) real
  - Minimum score of the instances of the model to be found.
  - Default value: 0.5
  - Suggested values: \( \text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  - Typical range of values: \( 0 \leq \text{MinScore} \leq 1 \)
  - Minimum increment: 0.01
  - Recommended increment: 0.05

- **NumMatches** (input_control)
  - integer \( \sim \) integer
  - Number of instances of the model to be found (or 0 for all matches).
  - Default value: 1
  - Suggested values: \( \text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\} \)

- **MaxOverlap** (input_control)
  - real \( \sim \) real
  - Maximum overlap of the instances of the model to be found.
  - Default value: 0.5
  - Suggested values: \( \text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)
  - Typical range of values: \( 0 \leq \text{MaxOverlap} \leq 1 \)
  - Minimum increment: 0.01
  - Recommended increment: 0.05

- **SubPixel** (input_control)
  - string(-array) \( \sim \) string
  - Subpixel accuracy if not equal to 'none'.
  - Default value: 'least_squares'
  - Suggested values: \( \text{SubPixel} \in \{'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'\} \)

- **NumLevels** (input_control)
  - integer(-array) \( \sim \) integer
  - Number of pyramid levels used in the matching (and lowest pyramid level to use if \( |\text{NumLevels}| = 2 \)).
  - Default value: 0
  - List of values: \( \text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\} \)
\[ \textbf{Greediness (input\_control)} \quad \text{real} \quad \Rightarrow \text{real} \quad \]

“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).

\textbf{Default value: 0.9}

\textbf{Suggested values:} Greediness \( \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)

\textbf{Typical range of values:} 0 \leq \text{Greediness} \leq 1

\textbf{Minimum increment:} 0.01

\textbf{Recommended increment:} 0.05

\[ \textbf{Row (output\_control)} \quad \text{point}\_y\text{-array} \quad \Rightarrow \text{real} \quad \]

Row coordinate of the found instances of the model.

\[ \textbf{Column (output\_control)} \quad \text{point}\_x\text{-array} \quad \Rightarrow \text{real} \quad \]

Column coordinate of the found instances of the model.

\[ \textbf{Angle (output\_control)} \quad \text{angle}\_rad\text{-array} \quad \Rightarrow \text{real} \quad \]

Rotation angle of the found instances of the model.

\[ \textbf{Scale (output\_control)} \quad \text{number}\text{-array} \quad \Rightarrow \text{real} \quad \]

Scale of the found instances of the model.

\[ \textbf{Score (output\_control)} \quad \text{real}\text{-array} \quad \Rightarrow \text{real} \quad \]

Score of the found instances of the model.

\textbf{Example}

\begin{verbatim}
create_scaled_shape_model (ImageReduced, 0, rad(-45), rad(180), 0, \n  0.9, 1.1, 0, 'none', 'use_polarity', \n  30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_scaled_shape_model (SearchImage, ModelID, rad(-45), rad(180), \n  0.9, 1.1, 0.5, 1, 0.5, 'interpolation', \n  0, 0, Row, Column, Angle, Scale, Score)
* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2DTmp)
hom_mat2d_scale (HomMat2DTmp, Scale, Scale, Row, Column, HomMat2DObject)
* Calculate true position of the model origin in the search image
affine_trans_pixel (HomMat2DObject, 0, 0, RowObject, ColObject)
* Display results
dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \n  Scale, 1, 0)
\end{verbatim}

\textbf{Result}

If the parameter values are correct, the operator \textit{find_scaled_shape_model} returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via \textit{set_system} ('no_object_result',<Result>). If necessary, an exception is raised.

\textbf{Execution Information}

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

\textbf{Possible Predecessors}

\textit{create_scaled_shape_model, read_shape_model, set_shape_model_origin, set_shape_model_clutter}

\textbf{Possible Successors}

\textit{clear_shape_model}

\textbf{Alternatives}

\textit{find_shape_model, find_aniso_shape_model, find_shape_models, find_scaled_shape_models, find_aniso_shape_models, find_ncc_model, find_ncc_models}

Module

Matching

find_scaled_shape_models ( Image : : ModelIDs, AngleStart, AngleExtent, ScaleMin, ScaleMax, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, Scale, Score, Model )

Find the best matches of multiple isotropically scaled shape models.

The operator find_scaled_shape_models finds the best NumMatches instances of the isotropically scaled shape models that are passed in ModelIDs in the input image Image. The models must have been created previously by calling create_scaled_shape_model or read_shape_model. In contrast to find_scaled_shape_model, multiple models can be searched in the same image in one call.

The position, rotation, and scale of the found instances of the model are returned in Row, Column, Angle, and Scale. The score of each found instance is returned in Score. The type of the found instances of the models is returned in Model. For details see respective sections below.

Characteristics of the parameter semantics

Compared to find_scaled_shape_model, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as ModelIDs, in which case each parameter element refers to the corresponding element in ModelIDs. (NumLevels may also contain either two or twice the number of elements as ModelIDs.) More details can be found below in the sections containing information for the respective parameters. Note that a call to find_scaled_shape_models with multiple values for ModelIDs, NumMatches and MaxOverlap has the same effect as multiple independent calls to find_scaled_shape_model with the respective parameters. However, a single call to find_scaled_shape_models is considerably more efficient.

Input parameters in detail

The image and its domain: The domain of the Image determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with create_scaled_shape_model. A different origin set with set_shape_model_origin is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than MinScore (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below 2^{NumLevels-1}. This behavior can be changed with set_system('border_shape_models','true') for all models or with set_shape_model_param(ModelID, 'border_shape_models','true') for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than MinScore. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by 2^{NumLevels-1} using, e.g., dilation_circle.

As usual, the domain of the input Image is used to restrict the search space for the reference point of the models ModelIDs. Consistent with the above semantics, the input Image can therefore contain a single image object or an image object tuple containing multiple image objects. If Image contains a single image object, its domain is used as the region of interest for all models in ModelIDs. If Image contains multiple image objects, each domain is used as the region of interest for the corresponding model in ModelIDs. In this case, the images have to be identical except for their domains, i.e., Image cannot be constructed in an arbitrary manner using concat_obj, but must be created from the same image using add_channels or equivalent calls. If this is not the case, an error message is returned.

HALCON 20.11.0.0
AngleStart, AngleExtent, ScaleMin, ScaleMax:  The parameters AngleStart and AngleExtent determine the range of rotations for which the model is searched. The parameters ScaleMin and ScaleMax determine the range of scales for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with create_scaled_shape_model. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. AngleStart and AngleExtent as well as ScaleMin and ScaleMax are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore:  The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below MinScore are found.

If a single value is passed in MinScore, this value is applied to found instances of all models. If, on the other hand, MinScore contains multiple values, the values are applied separately for the respective model. In case that the shape models have been extended by clutter parameters with set_shape_model_clutter and thus 'use_clutter' is enabled, MinScore expects for each minimum score an additional value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for 'use_clutter'. If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, MinScore must contain twice the number of elements as ModelIDs. In this case, the minimum score and the maximum clutter must be specified interleaved in MinScore. If, for example, two models are specified in ModelIDs, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, MinScore = [0.9, 0.1, 0.8, 0.2] must be selected.

NumMatches:  The maximum number of instances to be found can be determined with NumMatches. If more than NumMatches instances with a score greater than MinScore are found in the image, only the best NumMatches instances are returned. If fewer than NumMatches are found, only that number is returned, i.e., the parameter MinScore takes precedence over NumMatches. If all model instances exceeding MinScore in the image should be found, NumMatches must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on NumMatches. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for NumMatches set to 1 might be different from the match with the highest score returned when setting NumMatches to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score. In case that the shape models have been extended by clutter parameters using set_shape_model_clutter, NumMatches also considers the second value passed in MinScore: If more than NumMatches instances with a score greater than the first entry of MinScore and a clutter value smaller than the second entry of MinScore are found in the image, only the best NumMatches instances with respect to clutter are returned. Still, MinScore takes precedence over NumMatches and NumMatches must be set to 0 if all model instances fulfilling the conditions imposed by MinScore should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0.

If NumMatches contains one element, find_scaled_shape_models returns the best NumMatches instances of the model irrespective of the type of the model. If, for example, two models are passed in ModelIDs and NumMatches = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, NumMatches contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in NumMatches. If, for example, NumMatches = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.
MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap`, only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap = 0`, the found instances may not overlap at all, while for `MaxOverlap = 1` all instances are returned. If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle and scale resolution that was specified with `create_scaled_shape_model`. If `SubPixel` is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to ‘interpolation’, this mode requires additional computation time. The different modes for least-squares adjustment (‘least_squares’, ‘least_squares_high’, and ‘least_squares_weather_high’) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to ‘interpolation’. If least-squares adjustment is desired, ‘least_squares’ should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value ‘max_deformation’ followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value ‘max_deformation 2’ must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value ‘max_deformation 0’ corresponds to a search without allowing deformations, i.e., the behavior is the same as if no ‘max_deformation’ is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if ‘max_deformation’ and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either ‘max_deformation’ or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if ‘least_squares’, ‘least_squares_high’, or ‘least_squares_weather_high’ (see above) is chosen for the subpixel extraction (in comparison to ‘none’ or ‘interpolation’). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in ModelIDs exactly one value for the subpixel extraction must be passed in `SubPixel`. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in ModelIDs and for the first model the subpixel extraction is set to ‘interpolation’ and...
no object deformations are allowed and for the second model the subpixel extraction is set to 'least_squares' and a maximum object deformation of 3 pixels is allowed, then the tuple ['interpolation', 'least_squares', 'max_deformation 3'] must be passed in SubPixel. Alternatively, the equivalent tuple ['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3'] may be passed.

**NumLevels:** The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_scaled_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_scaled_shape_model is used. In certain cases, the number of pyramid levels that was determined automatically with, for example, create_scaled_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_scaled_shape_models. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least 'least_squares'. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, NumLevels must contain twice the number of elements as ModelIDs. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in NumLevels. If, for example, two models are specified in ModelIDs, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, NumLevels = [5,2,4,1] must be selected. If exactly two models are specified in ModelIDs, a special case occurs. If in this case the lowest pyramid level to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in NumLevels is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in NumLevels. If, e.g., NumLevels is set to [-5,2,-4,-1], the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to -1. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If a model was adapted with adapt_shape_model_high_noise the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing explicitly the lowest pyramid level as described above.

**Greediness:** The parameter Greediness determines how “greedily” the search should be carried out. If Greediness = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If Greediness = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For Greediness = 1, the maximum search
speed is achieved. In almost all cases, the shape model will always be found for \( \text{Greediness} = 0.9 \).

### Output parameters in detail

**Row, Column, Angle and Scale:** The position, rotation, and scale of the found instances of the model are returned in \( \text{Row, Column, Angle, and Scale} \). The coordinates \( \text{Row} \) and \( \text{Column} \) are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with \( \text{create_scaled_shape_model} \). A different origin can be set with \( \text{set_shape_model_origin} \).

Note that the coordinates \( \text{Row} \) and \( \text{Column} \) do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for \( \text{find_scaled_shape_model} \) shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure \( \text{dev_display_shape_matching_results} \) can be used.

**Score:** The score of each found instance is returned in \( \text{Score} \). The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using \( \text{set_shape_model_clutter} \), following the above values \( \text{Score} \) also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, \( \text{Score} = [0.9, 0.8, 0.2, 0.1] \) is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Model:** The type of the found instances of the models is returned in \( \text{Model} \). The elements of \( \text{Model} \) are indices into the tuple \( \text{ModelIDs} \), i.e., they can contain values from 0 to \(|\text{ModelIDs}|−1\). Hence, a value of 0 in an element of \( \text{Model} \) corresponds to an instance of the first model in \( \text{ModelIDs} \).

### Specifying a timeout

Using the operator \( \text{set_shape_model_param} \) you can specify a 'timeout' for \( \text{find_scaled_shape_models} \). If the shape models referenced by \( \text{ModelIDs} \) hold different values for 'timeout', \( \text{find_scaled_shape_models} \) uses the smallest one. If \( \text{find_scaled_shape_models} \) reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Depending on the scaling range specified by \( \text{ScaleMin} \) and \( \text{ScaleMax} \), \( \text{find_scaled_shape_models} \) needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of \( \text{find_scaled_shape_models} \) exceeds the value of the specified 'timeout' by this time.

**MinContrast with multiple models**

Please note, that the different models that are given with the parameter \( \text{ModelIDs} \) should have been created with the same value of \( \text{MinContrast} \). If they were created with different values for \( \text{MinContrast} \), \( \text{find_scaled_shape_models} \) will use the smallest of these values.

### Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure \( \text{dev_display_shape_matching_results} \).

### Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

---

Parameters

- **Image** (input_object) .................................................. (multichannel-)image(-array) \( \sim \text{object : byte / uint2} \)
  Input image in which the models should be found.

- **ModelIDs** (input_control) .................................................. shape_model(-array) \( \sim \text{handle} \)
  Handle of the models.
**AngleStart** (input_control) .............................................. angle.rad(-array) \(\sim\) real
Smallest rotation of the models.
Default value: -0.39
Suggested values: \(\text{AngleStart} \in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}\)

**AngleExtent** (input_control) .......................................... angle.rad(-array) \(\sim\) real
Extent of the rotation angles.
Default value: 0.78
Suggested values: \(\text{AngleExtent} \in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}\)
Restriction: \(\text{AngleExtent} \geq 0\)

**ScaleMin** (input_control) .............................................. number(-array) \(\sim\) real
Minimum scale of the models.
Default value: 0.9
Suggested values: \(\text{ScaleMin} \in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
Restriction: \(\text{ScaleMin} > 0\)

**ScaleMax** (input_control) .............................................. number(-array) \(\sim\) real
Maximum scale of the models.
Default value: 1.1
Suggested values: \(\text{ScaleMax} \in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}\)
Restriction: \(\text{ScaleMax} \geq \text{ScaleMin}\)

**MinScore** (input_control) .............................................. real(-array) \(\sim\) real
Minimum score of the instances of the models to be found.
Default value: 0.5
Suggested values: \(\text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
Typical range of values: \(0 \leq \text{MinScore} \leq 1\)
Minimum increment: 0.01
Recommended increment: 0.05

**NumMatches** (input_control) ........................................ integer(-array) \(\sim\) integer
Number of instances of the models to be found (or 0 for all matches).
Default value: 1
Suggested values: \(\text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\}\)

**MaxOverlap** (input_control) ......................................... real(-array) \(\sim\) real
Maximum overlap of the instances of the models to be found.
Default value: 0.5
Suggested values: \(\text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
Typical range of values: \(0 \leq \text{MaxOverlap} \leq 1\)
Minimum increment: 0.01
Recommended increment: 0.05

**SubPixel** (input_control) .............................................. string(-array) \(\sim\) string
Subpixel accuracy if not equal to ‘none’.
Default value: ‘least_squares’
Suggested values: \(\text{SubPixel} \in \{\text{'none'}, \text{'interpolation'}, \text{'least_squares'}, \text{'least_squares_high'}, \text{'least_squares_very_high'}, \text{'max_deformation 1'}, \text{'max_deformation 2'}, \text{'max_deformation 3'}, \text{'max_deformation 4'}, \text{'max_deformation 5'}, \text{'max_deformation 6'}\}\)

**NumLevels** (input_control) ............................................ integer(-array) \(\sim\) integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).
Default value: 0
List of values: \(\text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}\)

**Greediness** (input_control) ........................................... real(-array) \(\sim\) real
“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default value: 0.9
Suggested values: \(\text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}\)
Typical range of values: \(0 \leq \text{Greediness} \leq 1\)
Minimum increment: 0.01
Recommended increment: 0.05

**Row** (output_control) ................................................ point.y-array \(\sim\) real
Row coordinate of the found instances of the models.

**Column** (output_control) ............................................. point.x-array \(\sim\) real
Column coordinate of the found instances of the models.
18.5. SHAPE-BASED

- **Angle** (output_control) .......................................................... angle. rad-array ~ real
  Rotation angle of the found instances of the models.
- **Scale** (output_control) ............................................................ number-array ~ real
  Scale of the found instances of the models.
- **Score** (output_control) ............................................................ real-array ~ real
  Score of the found instances of the models.
- **Model** (output_control) ............................................................ integer-array ~ integer
  Index of the found instances of the models.

Example

```halcon
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
cREATE_scaled_shape_model (ImageReduced1,'auto', -0.39, 0.79, 'auto', 0.9, \1.1, 'auto', 'auto', 'use_polarity', 'auto', \'auto', ModelID1)
cREATE_scaled_shape_model (ImageReduced2, 'auto', -0.39, 0.79, 'auto', 0.9, \1.1, 'auto', 'auto', 'use_polarity', 'auto', \'auto', ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_scaled_shape_models (Image, ModelIDs, -0.39, 0.78, 0.9, 1.1, 0.5, 1, \0.5, 'least_squares', 0, 0.9, Row, Column, Angle, \Scale, Score, Model)
```

* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, \Scale, 1, Model)

Result

If the parameter values are correct, the operator `find_scaled_shape_models` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system` (‘no_object_result’,<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

Matching
The maximum number of instances to be found can be determined with the parameter \texttt{MinScore}. The parameters \texttt{AngleStart} and \texttt{AngleExtent} determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with \texttt{create_shape_model}. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. \texttt{AngleStart} and \texttt{AngleExtent} are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger \texttt{MinScore} is chosen, the faster the search is. If the model can be expected never to be occluded in the images, \texttt{MinScore} may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below), it might happen that instances with a score slightly below \texttt{MinScore} are found.

In case that the shape model has been extended by clutter parameters with \texttt{set_shape_model_clutter} and thus ‘\texttt{use_clutter}’ is enabled, \texttt{MinScore} expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0. Changing this second value does not influence the runtime.

The maximum number of instances to be found can be determined with \texttt{NumMatches}. If more than \texttt{NumMatches} instances with a score greater than \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances are returned. If fewer than \texttt{NumMatches} are found, only that number is returned, i.e., the parameter \texttt{MinScore} takes precedence over \texttt{NumMatches}. If all model instances exceeding \texttt{MinScore} in the image should be found, \texttt{NumMatches} must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on \texttt{NumMatches}. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for \texttt{NumMatches} set to 1 might be different from the match with the highest score returned when setting \texttt{NumMatches} to 0 or > 1.

\begin{verbatim}
find_shape_model ( Image : ModelID, AngleStart, AngleExtent, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, Score )
\end{verbatim}

Find the best matches of a shape model in an image.

The operator \texttt{find_shape_model} finds the best \texttt{NumMatches} instances of the shape model \texttt{ModelID} in the input image \texttt{Image}. The model must have been created previously by calling \texttt{create_shape_model} or \texttt{read_shape_model}.

The position and rotation of the found instances of the model is returned in \texttt{Row}, \texttt{Column}, and \texttt{Angle}. Additionally, the score of each found instance is returned in \texttt{Score}.

Input parameters in detail

The domain of the image \texttt{Image} determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with \texttt{create_shape_model}. A different origin set with \texttt{set_shape_model_origin} is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than \texttt{MinScore} (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\texttt{NumLevels}-1}$. This behavior can be changed with \texttt{set_system(‘border_shape_models’,’true’)} for all models or with \texttt{set_shape_model_param(ModelID, ’border_shape_models’,’true’)} for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than \texttt{MinScore}. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\texttt{NumLevels}-1}$ using, e.g., \texttt{dilation_circle}.

\texttt{AngleStart} and \texttt{AngleExtent}: The parameters \texttt{AngleStart} and \texttt{AngleExtent} determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with \texttt{create_shape_model}. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. \texttt{AngleStart} and \texttt{AngleExtent} are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

\texttt{MinScore}: The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger \texttt{MinScore} is chosen, the faster the search is. If the model can be expected never to be occluded in the images, \texttt{MinScore} may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below \texttt{MinScore} are found.

In case that the shape model has been extended by clutter parameters with \texttt{set_shape_model_clutter} and thus ‘\texttt{use_clutter}’ is enabled, \texttt{MinScore} expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0. Changing this second value does not influence the runtime.

\texttt{NumMatches}: The maximum number of instances to be found can be determined with \texttt{NumMatches}. If more than \texttt{NumMatches} instances with a score greater than \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances are returned. If fewer than \texttt{NumMatches} are found, only that number is returned, i.e., the parameter \texttt{MinScore} takes precedence over \texttt{NumMatches}. If all model instances exceeding \texttt{MinScore} in the image should be found, \texttt{NumMatches} must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on \texttt{NumMatches}. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for \texttt{NumMatches} set to 1 might be different from the match with the highest score returned when setting \texttt{NumMatches} to 0 or > 1.
If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise NumMatches, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using set_shape_model_clutter, NumMatches also considers the second value passed in MinScore. Matched instances will be in this case instances with a score greater than the first entry of MinScore and a clutter value smaller than its second entry. If the number of matched instances in the image is larger than NumMatches, the best NumMatches instances with respect to clutter values are returned. Still, MinScore takes precedence over NumMatches and NumMatches must be set to 0 if all model instances fulfilling the conditions imposed by MinScore should be returned. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and NumMatches set to 0.

**MaxOverlap**: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter MaxOverlap determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

**SubPixel**: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with create_shape_model. If SubPixel is set to 'interpolation' (or 'true') the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed.

Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max_deformation' and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max_deformation' or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares_very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to...
The position and rotation of the found instances of the model is returned in Row, Column and Angle:

**Output parameters in detail**

The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_shape_model. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4, 2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least 'least_squares'. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in NumLevels. If, e.g., NumLevels is set to [4, -2], the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If the ModelID was adapted with adapt_shape_model_high_noise the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing two values to NumLevels and explicitly setting the lowest pyramid level.

Greediness: The parameter Greediness determines how “greedily” the search should be carried out. If Greediness = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If Greediness = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For Greediness = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for Greediness = 0.9.

Output parameters in detail

Row, Column and Angle: The position and rotation of the found instances of the model is returned in Row, Column, and Angle. The coordinates Row and Column are related to the position of the origin of the shape model in the search image. However, Row and Column do not exactly correspond to this position. Instead, find_shape_model returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see affine_trans_pixel). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.
By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin can be set with `set_shape_model_origin`.

**Score:** The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, `Score = [0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

**Specifying a timeout**

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_shape_model`. If `find_shape_model` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

**Visualization of the results**

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

**Further Information**

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

| Parameters |  
| --- | --- |
| **Image** (input_object) .............................................(multichannel-)image  \(\sim\) object : byte / uint2  
Input image in which the model should be found. |  
| **ModelID** (input_control) .......................................... shape_model  \(\sim\) handle  
Handle of the model. |  
| **AngleStart** (input_control) ......................................angle.rad  \(\sim\) real  
Smallest rotation of the model.  
Default value: -0.39  
Suggested values: AngleStart \(\in\) \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\} |  
| **AngleExtent** (input_control) .................................angle.rad  \(\sim\) real  
Extent of the rotation angles.  
Default value: 0.79  
Suggested values: AngleExtent \(\in\) \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}  
Restriction: AngleExtent \(\geq\) 0 |  
| **MinScore** (input_control) ........................................ real(-array)  \(\sim\) real  
Minimum score of the instances of the model to be found.  
Default value: 0.5  
Suggested values: MinScore \(\in\) \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}  
Typical range of values: 0 \(\leq\) MinScore \(\leq\) 1  
Minimum increment: 0.01  
Recommended increment: 0.05 |  
| **NumMatches** (input_control) ...................................... integer  \(\sim\) integer  
Number of instances of the model to be found (or 0 for all matches).  
Default value: 1  
Suggested values: NumMatches \(\in\) \{0, 1, 2, 3, 4, 5, 10, 20\} |  
| **MaxOverlap** (input_control) ...................................... real  \(\sim\) real  
Maximum overlap of the instances of the model to be found.  
Default value: 0.5  
Suggested values: MaxOverlap \(\in\) \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}  
Typical range of values: 0 \(\leq\) MaxOverlap \(\leq\) 1  
Minimum increment: 0.01  
Recommended increment: 0.05 |
SubPixel (input_control) .................................................. string(-array) \sim string
Subpixel accuracy if not equal to 'none'.
 Default value: 'least_squares'
 Suggested values: SubPixel \in \{ 'none', 'interpolation', 'least_squares', 'least_squares_high',
 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3',
 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'\}

NumLevels (input_control) ........................................... integer(-array) \sim integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
 Default value: 0
 List of values: NumLevels \in \{ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \}

Greediness (input_control) ........................................... real \sim real
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
 Default value: 0.9
 Suggested values: Greediness \in \{ 0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0 \}
 Typical range of values: 0 \leq Greediness \leq 1
 Minimum increment: 0.01
 Recommended increment: 0.05

Row (output_control) ............................................... point.y-array \sim real
Row coordinate of the found instances of the model.

Column (output_control) .......................................... point.x-array \sim real
Column coordinate of the found instances of the model.

Angle (output_control) ........................................... angle.rad-array \sim real
Rotation angle of the found instances of the model.

Score (output_control) ............................................ real-array \sim real
Score of the found instances of the model.

--- Example ---

create_shape_model (ImageReduced, 0, rad(-45), rad(180), 0, \ 'none', 'use_polarity', 30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_shape_model (SearchImage, ModelID, rad(-45), rad(180), \ 0.5, 1, 0.5, 'interpolation', \ 0, 0, Row, Column, Angle, Score)
* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2DObject)
* Display results
dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \ 1, 1, 0)

--- Result ---
If the parameter values are correct, the operator find_shape_model returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

--- Execution Information ---

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Automatically parallelized on internal data level.

--- Possible Predecessors ---
create_shape_model, read_shape_model, set_shape_model_origin,
set_shape_model_clutter

--- Possible Successors ---
clear_shape_model

--- Alternatives ---
find_scaled_shape_model, find_aniso_shape_model, find_scaled_shape_models,
find_shape_models, find_aniso_shape_models, find_ncc_model, find_ncc_models

Module

Matching

**find_shape_models** ( Image : ModelIDs, AngleStart, AngleExtent, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, Score, Model )

Find the best matches of multiple shape models.

The operator **find_shape_models** finds the best **NumMatches** instances of the shape models that are passed in the tuple **ModelIDs** in the input image **Image**. The models must have been created previously by calling **create_shape_model** or **read_shape_model**. In contrast to **find_shape_model**, multiple models can be searched in the same image in one call.

The position and rotation of the found instances of the model is returned in **Row**, **Column**, and **Angle**. The score of each found instance is returned in **Score**. The type of the found instances of the models is returned in **Model**. For details see respective sections below.

**Characteristics of the parameter semantics**

Compared to **find_shape_model**, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as **ModelIDs**, in which case each parameter element refers to the corresponding element in **ModelIDs**. (**NumLevels** may also contain either two or twice the number of elements as **ModelIDs**.) More details can be found below in the sections containing information for the respective parameters. Note that a call to **find_shape_models** with multiple values for **ModelIDs**, **NumMatches** and **MaxOverlap** has the same effect as multiple independent calls to **find_shape_model** with the respective parameters. However, a single call to **find_shape_models** is considerably more efficient.

**Input parameters in detail**

**The image and its domain:** The domain of the **Image** determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with **create_shape_model**. A different origin set with **set_shape_model_origin** is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than **MinScore** (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{\text{NumLevels}-1}$. This behavior can be changed with **set_system**('border_shape_models','true') for all models or with **set_shape_model_param**(ModelID, 'border_shape_models','true') for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than **MinScore**. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{\text{NumLevels}-1}$ using, e.g., **dilation_circle**.

As usual, the domain of the input **Image** is used to restrict the search space for the reference point of the models **ModelIDs**. Consistent with the above semantics, the input **Image** can therefore contain a single image object or an image object tuple containing multiple image objects. If **Image** contains a single image object, its domain is used as the region of interest for all models in **ModelIDs**. If **Image** contains multiple image objects, each domain is used as the region of interest for the corresponding model in **ModelIDs**. In this case, the images have to be identical except for their domains, i.e., **Image** cannot be constructed in an arbitrary manner using **concat_obj**, but must be created from the same image using **add_channels** or equivalent calls. If this is not the case, an error message is returned.

**AngleStart and AngleExtent:** The parameters **AngleStart** and **AngleExtent** determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when
the model was created with \texttt{create_shape_model}. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. \texttt{AngleStart} and \texttt{AngleExtent} are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

\textbf{MinScore:} The parameter \texttt{MinScore} determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger \texttt{MinScore} is chosen, the faster the search is. If the model can be expected never to be occluded in the images, \texttt{MinScore} may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below \texttt{MinScore} are found.

If a single value is passed in \texttt{MinScore}, this value is applied to found instances of all models. If, on the other hand, \texttt{MinScore} contains multiple values, the values are applied separately for the respective model.

In case that the shape models have been extended by clutter parameters with \texttt{set_shape_model_clutter} and thus \texttt{’use_clutter’} is enabled, \texttt{MinScore} expects for each minimum score an additional value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for \texttt{’use_clutter’}.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, \texttt{MinScore} must contain twice the number of elements as \texttt{ModelIDs}. In this case, the minimum score and the maximum clutter must be specified interleaved in \texttt{MinScore}. If, for example, two models are specified in \texttt{ModelIDs}, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, \texttt{MinScore} = \{0.9, 0.1, 0.8, 0.2\} must be selected.

\textbf{NumMatches:} The maximum number of instances to be found can be determined with \texttt{NumMatches}. If more than \texttt{NumMatches} instances with a score greater than \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances are returned. If fewer than \texttt{NumMatches} are found, only that number is returned, i.e., the parameter \texttt{MinScore} takes precedence over \texttt{NumMatches}. If all model instances exceeding \texttt{MinScore} in the image should be found, \texttt{NumMatches} must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on \texttt{NumMatches}. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for \texttt{NumMatches} set to \texttt{1} might be different from the match with the highest score returned when setting \texttt{NumMatches} to 0 or \texttt{> 1}. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise \texttt{NumMatches}, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using \texttt{set_shape_model_clutter}, \texttt{NumMatches} also considers the second value passed in \texttt{MinScore}: If more than \texttt{NumMatches} instances with a score greater than the first entry of \texttt{MinScore} and a clutter value smaller than the second entry of \texttt{MinScore} are found in the image, only the best \texttt{NumMatches} instances with respect to clutter are returned. Still, \texttt{MinScore} takes precedence over \texttt{NumMatches} and \texttt{NumMatches} must be set to 0 if all model instances fulfilling the conditions imposed by \texttt{MinScore} should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and \texttt{NumMatches} set to 0.

If \texttt{NumMatches} contains one element, \texttt{find_shape_models} returns the best \texttt{NumMatches} instances of the model irrespective of the type of the model. If, for example, two models are passed in \texttt{ModelIDs} and \texttt{NumMatches} = \texttt{2} is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, \texttt{NumMatches} contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in \texttt{NumMatches}. If, for example, \texttt{NumMatches} = \{1, 1\} is selected, one instance of the first model and one instance of the second model is returned.

\textbf{MaxOverlap:} If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter \texttt{MaxOverlap} determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances,
and hence to be returned separately. If two instances overlap each other by more than MaxOverlap only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see smallest_rectangle2) of the found instances. If MaxOverlap = 0, the found instances may not overlap at all, while for MaxOverlap = 1 all instances are returned.

If a single value is passed in MaxOverlap, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in MaxOverlap, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that too much overlap are eliminated. In this mode, models of different types may overlap completely.

**SubPixel**: The parameter SubPixel determines whether the instances should be extracted with subpixel accuracy. If SubPixel is set to 'none' (or 'false' for backwards compatibility) the model’s pose is only determined with pixel accuracy and the angle resolution that was specified with create_shape_model. If SubPixel is set to 'interpolation' (or 'true') the position as well as the rotation are determined with subpixel accuracy. In this mode, the model’s pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model’s pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, SubPixel should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter SubPixel. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in SubPixel in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max_deformation' and AngleExtent are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max_deformation' or AngleExtent to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares_very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in ModelIDs exactly one value for the subpixel extraction must be passed in SubPixel. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in ModelIDs and for the first model the subpixel extraction is set to 'interpolation' and no object deformations are allowed and for the second model the subpixel extraction is set to 'least_squares' and a maximum object deformation of 3 pixels is allowed, then the tuple ['interpolation', 'least_squares', 'max_deformation 3'] must be passed in SubPixel. Alternatively, the equivalent tuple ['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3'] may be passed.
NumLevels: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the shape model was created with create_shape_model. If NumLevels is set to 0, the number of pyramid levels specified in create_shape_model is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, create_shape_model may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting MinScore to a very low value to find all matches, it may be better to query the value of NumLevels with get_shape_model_params and then use a slightly lower value in find_shape_models. This approach is often better regarding the speed and robustness of the matching.

Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, SubPixel should be set to at least 'least_squares'. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, NumLevels must contain twice the number of elements as ModelIDs. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in NumLevels. If, for example, two models are specified in ModelIDs, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, NumLevels = [5,2,4,1] must be selected. If exactly two models are specified in ModelIDs, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in NumLevels is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called ‘increased tolerance mode’, the lowest pyramid level must be specified negatively in NumLevels. If, e.g., NumLevels is set to [5,2,4,-1], the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to -1. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If a model was adapted with adapt_shape_model_high_noise the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing explicitly the lowest pyramid level as described above.

Greediness: The parameter Greediness determines how “greedily” the search should be carried out. If Greediness = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If Greediness = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For Greediness = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for Greediness = 0.9.

Output parameters in detail

Row, Column and Angle: The position and rotation of the found instances of the model is returned in Row,
Column, and Angle. The coordinates Row and Column are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with create_shape_model. A different origin can be set with set_shape_model_origin.

Note that the coordinates Row and Column do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for find_shape_model shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure dev_display_shape_matching_results can be used.

Score: The score of each found instance is returned in Score. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using set_shape_model_clutter, following the above values Score also returns the clutter values of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter value will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter value is 0.2 for the first instance and 0.1 for the second instance, Score = [0.9, 0.8, 0.2, 0.1] is returned. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

Model: The type of the found instances of the models is returned in Model. The elements of Model are indices into the tuple ModelIDs, i.e., they can contain values from 0 to |ModelIDs| - 1. Hence, a value of 0 in an element of Model corresponds to an instance of the first model in ModelIDs.

Specifying a timeout
Using the operator set_shape_model_param you can specify a ‘timeout’ for find_shape_models. If the shape models referenced by ModelIDs hold different values for ‘timeout’, find_shape_models uses the smallest one. If find_shape_models reaches this ‘timeout’, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

MinContrast with multiple models
Please note, that the different models that are given with the parameter ModelIDs should have been created with the same value of MinContrast. If they were created with different values for MinContrast, find_shape_models will use the smallest of these values.

Visualization of the results
To display the results found by shape-based matching, we highly recommend the usage of the procedure dev_display_shape_matching_results.

Further Information
For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

CHAPTER 18 MATCHING

- **MinScore** (input_control) .................................................. real(-array) \(\sim \) real  
  Minimum score of the instances of the models to be found.  
  Default value: 0.5  
  Suggested values: \( \text{MinScore} \in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)  
  Typical range of values: \( 0 \leq \text{MinScore} \leq 1 \)  
  Minimum increment: 0.01  
  Recommended increment: 0.05

- **NumMatches** (input_control) ........................................... integer(-array) \(\sim\) integer  
  Number of instances of the models to be found (or 0 for all matches).  
  Default value: 1  
  Suggested values: \( \text{NumMatches} \in \{0, 1, 2, 3, 4, 5, 10, 20\} \)

- **MaxOverlap** (input_control) ............................................. real(-array) \(\sim\) real  
  Maximum overlap of the instances of the models to be found.  
  Default value: 0.5  
  Suggested values: \( \text{MaxOverlap} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)  
  Typical range of values: \( 0 \leq \text{MaxOverlap} \leq 1 \)  
  Minimum increment: 0.01  
  Recommended increment: 0.05

- **SubPixel** (input_control) ............................................. string(-array) \(\sim\) string  
  Subpixel accuracy if not equal to ‘none’.  
  Default value: ‘least_squares’  
  Suggested values: \( \text{SubPixel} \in \{\text{’none’}, \text{’interpolation’}, \text{’least_squares’}, \text{’least_squares_high’}, \text{’least_squares_very_high’}, \text{’max_deformation 1’}, \text{’max_deformation 2’}, \text{’max_deformation 3’}, \text{’max_deformation 4’}, \text{’max_deformation 5’}, \text{’max_deformation 6’}\} \)

- **NumLevels** (input_control) ............................................ integer(-array) \(\sim\) integer  
  Number of pyramid levels used in the matching (and lowest pyramid level to use if \(|\text{NumLevels}| = 2\)).  
  Default value: 0  
  List of values: \( \text{NumLevels} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\} \)

- **Greediness** (input_control) ........................................... real(-array) \(\sim\) real  
  “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).  
  Default value: 0.9  
  Suggested values: \( \text{Greediness} \in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\} \)  
  Typical range of values: \( 0 \leq \text{Greediness} \leq 1 \)  
  Minimum increment: 0.01  
  Recommended increment: 0.05

- **Row** (output_control) .................................................. point.y-array \(\sim\) real  
  Row coordinate of the found instances of the models.

- **Column** (output_control) .............................................. point.x-array \(\sim\) real  
  Column coordinate of the found instances of the models.

- **Angle** (output_control) .............................................. angle.rad-array \(\sim\) real  
  Rotation angle of the found instances of the models.

- **Score** (output_control) .............................................. real-array \(\sim\) real  
  Score of the found instances of the models.

- **Model** (output_control) ............................................. integer-array \(\sim\) integer  
  Index of the found instances of the models.

--- Example ---

HALCON/HDevelop Reference Manual, 2020-11-10
ModelIDs:=[ModelID1, ModelID2]
find_shape_models (Image, ModelIDs, rad(-45), rad(90), 0.7, [1,1], 0.5, \\
'least_squares', 0, 1, Row, Column, Angle, Score, Model)
* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, \\
1, 1, Model)

Result
If the parameter values are correct, the operator find_shape_models returns the value 2 (H_MSG_TRUE).
If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Module

get_shape_model_clutter ( : ClutterRegion : ModelID, 
                    GenParamName : GenParamValue, HomMat2D, ClutterContrast )

Get the clutter parameters of a shape model.
The operator get_shape_model_clutter can be used to inspect clutter parameters of the shape model ModelID, which have been set previously using set_shape_model_clutter. Also, the value of 'use_clutter', which can be set using set_shape_model_param, can be queried by setting GenParamName to 'use_clutter'. For a description of the parameters, please see set_shape_model_clutter and set_shape_model_param.

Parameters

▷ ClutterRegion (output_object) ..................................................region 〜 object Region where no clutter should occur.
▷ ModelID (input_control) .....................................................shape_model 〜 handle Handle of the model.
▷ GenParamName (input_control) .........................................attribute.name(-array) 〜 string Parameter names.
  Default value: 'use_clutter'
  List of values: GenParamName ∈ ['use_clutter', 'clutter_border_mode']
▷ GenParamValue (output_control) ................................attribute.name(-array) 〜 string / real / integer Parameter values.
▷ HomMat2D (output_control) ..............................................hom_mat2d 〜 real Transformation matrix.
CHAPTER 18 MATCHING

ClutterContrast (output_control) ........................................... number ~ integer
Minimum contrast of clutter in the search images.

Result
If the parameters are valid, the operator get_shape_model_clutter returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

set_shape_model_param

Module
Matching

get_shape_model_contours ( : ModelContours : ModelID, Level : )

Return the contour representation of a shape model.

The operator get_shape_model_contours returns a representation of the shape model ModelID as XLD contours in ModelContours. The parameter Level determines for which pyramid level of the model the contour representation should be returned. The contours can be used, for example, to visualize the found instances of the model in an image. It should be noted that the position of ModelContours is normalized such that the reference point of the model (see set_shape_model_origin) lies at the pixel position (0, 0). Hence, the contours simply need to be translated to the found position in the image (and possibly rotated and scaled around this point).

Parameters

ModelContours (output_object) ........................................... xld_cont-array ~ object
Contour representation of the shape model.

ModelID (input_control) ..................................................... shape_model ~ handle
Handle of the model.

Level (input_control) ....................................................... integer ~ integer
Pyramid level for which the contour representation should be returned.
Default value: 1
Suggested values: Level ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: Level >= 1

Result
If the handle of the model is valid, the operator get_shape_model_contours returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
**get_shape_model_origin** ( : : ModelID : Row, Column )

Return the origin (reference point) of a shape model.

The operator `get_shape_model_origin` returns the origin (reference point) of the shape model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

**Parameters**

- **ModelID** (input_control) : handle  
  Handle of the model.
- **Row** (output_control) : point.y  
  Row coordinate of the origin of the shape model.
- **Column** (output_control) : point.x  
  Column coordinate of the origin of the shape model.

**Result**

If the handle of the model is valid, the operator `get_shape_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

---

**get_shape_model_params** ( : : ModelID : NumLevels, AngleStart, AngleExtent, AngleStep, ScaleMin, ScaleMax, ScaleStep, Metric, MinContrast )

Return the parameters of a shape model.
The operator `get_shape_model_params` returns the parameters of the shape model `ModelID` that were used to create it using `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. In particular, this output can be used to check the parameters `NumLevels`, `AngleStep`, `ScaleStep`, and `MinContrast` if they were determined automatically during the model creation with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`.

If the `ModelID` was adapted with `adapt_shape_model_high_noise`, `NumLevels` contains two values: the highest pyramid level and the estimated lowest pyramid level.

If the shape model was created using `create_shape_model` or `create_scaled_shape_model` a single value is returned in `ScaleMin`, `ScaleMax`, and `ScaleStep`. This parameters corresponds to the isotropic scaling parameters of the shape model. If the shape model was created using `create_aniso_shape_model` two values each are returned in the above three parameters. Here, the first value of the respective parameter refers to the scaling in the row direction, while the second value refers to the scaling in the column direction.

Note that the parameters `Optimization` and `Contrast` that also can be determined automatically during the model creation cannot be queried by using `get_shape_model_params`. If their value is of interest `determine_shape_model_params` should be used instead.

---

**Parameters**

- **ModelID** (input_control) ➔ `shape_model ~ handle`  
  Handle of the model.

- **NumLevels** (output_control) ➔ `integer(-array) ~ integer`  
  Number of pyramid levels.

- **AngleStart** (output_control) ➔ `angle.rad ~ real`  
  Smallest rotation of the pattern.

- **AngleExtent** (output_control) ➔ `angle.rad ~ real`  
  Extent of the rotation angles.  
  **Assertion:** `AngleExtent >= 0`

- **AngleStep** (output_control) ➔ `angle.rad ~ real`  
  Step length of the angles (resolution).  
  **Assertion:** `AngleStep >= 0 && AngleStep <= pi / 16`

- **ScaleMin** (output_control) ➔ `number(-array) ~ real`  
  Minimum scale of the pattern.  
  **Assertion:** `ScaleMin > 0`

- **ScaleMax** (output_control) ➔ `number(-array) ~ real`  
  Maximum scale of the pattern.  
  **Assertion:** `ScaleMax >= ScaleMin`

- **ScaleStep** (output_control) ➔ `number(-array) ~ real`  
  Scale step length (resolution).  
  **Assertion:** `ScaleStep >= 0`

- **Metric** (output_control) ➔ `string ~ string`  
  Match metric.

- **MinContrast** (output_control) ➔ `number ~ integer`  
  Minimum contrast of the objects in the search images.

---

**Result**

If the handle of the model is valid, the operator `get_shape_model_params` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Matching

inspect_shape_model ( Image : ModelImages,
           ModelRegions : NumLevels, Contrast : )

Create the representation of a shape model.

inspect_shape_model creates a representation of a shape model. The operator is particularly useful in order to determine the parameters NumLevels and Contrast, which are used in create_shape_model, create_scaled_shape_model, or create_aniso_shape_model, quickly and conveniently. The representation of the model is created on multiple image pyramid levels, where the number of levels is determined by NumLevels. In contrast to create_shape_model, create_scaled_shape_model, and create_aniso_shape_model, the model is only created for the rotation and scale of the object in the input image, i.e., 0° and 1. As output, inspect_shape_model creates an image object ModellImages containing the images of the individual levels of the image pyramid as well as a region in ModelRegions for each pyramid level that represents the model at the respective pyramid level. The individual objects can be accessed with select_obj. If the input image Image has one channel the representation of the model is created with the method that is used in create_shape_model, create_scaled_shape_model or create_aniso_shape_model for the metrics 'use_polarity', 'ignore_global_polarity', and 'ignore_local_polarity'. If the input image has more than one channel the representation is created with the method that is used for the metric 'ignore_color_polarity'. As described for create_shape_model, create_scaled_shape_model, and create_aniso_shape_model, the number of pyramid levels should be chosen as large as possible, while taking into account that the model must be recognizable on the highest pyramid level and must have enough model points. The parameter Contrast should be chosen such that only the significant features of the template object are used for the model. Contrast can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in edges_image. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see hysteresis_threshold. Optionally, Contrast can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in Contrast. In this case, the first two values can simply be set to identical values. In its typical use, inspect_shape_model is called interactively multiple times with different parameters for NumLevels and Contrast, until a satisfactory model is obtained. After this, create_shape_model, create_scaled_shape_model, or create_aniso_shape_model are called with the parameters thus obtained.

Parameters

- **Image** (input_object) (multichannel-image) ~ object : byte / uint2
  Input image.
- **ModelImages** (output_object) (multichannel-image-array) ~ object : byte / uint2
  Image pyramid of the input image
- **ModelRegions** (output_object) (region-array) ~ object
  Model region pyramid
- **NumLevels** (input_control) integer ~ integer
  Number of pyramid levels.
  Default value: 4
  List of values: NumLevels ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- **Contrast** (input_control) (number-array) ~ integer
  Threshold or hysteresis thresholds for the contrast of the object in the image and optionally minimum size of
the object parts.

Default value: 30

Suggested values: \( \text{Contrast} \in \{10, 20, 30, 40, 60, 80, 100, 120, 140, 160\} \)

If the parameters are valid, the operator \( \text{inspect\_shape\_model} \) returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

#### read\_shape\_model ( : : FileName : ModelID )

Read a shape model from a file.

The operator \( \text{read\_shape\_model} \) reads a shape model, which has been written with \( \text{write\_shape\_model} \), from the file \( \text{FileName} \). The default HALCON file extension for the shape model is 'shm'.

### Parameters

- **FileName** (input_control) : File name.
  - File extension: .shm
- **ModelID** (output_control) : Handle of the model.

If the file name is valid, the operator \( \text{read\_shape\_model} \) returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Module

Matching
Serialize a shape model.

`serialize_shape_model` serializes the data of a shape model (see `fwrite SerializedItemHandle` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_shape_model` is converted to a serialized item. The shape model is defined by the handle `ModelID`. The serialized shape model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_shape_model`.

### Parameters

- **ModelID** (input_control) `shape_model` ~ handle
  Handle of the model.
- **SerializedItemHandle** (output_control) `serialized_item` ~ handle
  Handle of the serialized item.

### Result

If the parameters are valid, the operator `serialize_shape_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Successors

`fwrite_serialized_item`, `send_serialized_item`, `deserialize_shape_model`

### Module

Set the clutter parameters of a shape model.

`set_shape_model_clutter` sets the clutter parameters of the shape model `ModelID`. In particular, a region is defined relative to the model contours, in which no (or too faint) clutter edges should occur in the search image. This is helpful, e.g., if it is a special characteristic of the model that, in specific parts near to the model, structures are missing.

For example, within the HDevelop example program `find_shape_model_clutter.hdev`, the model corresponds to a ball in a ball grid array (BGA). As the ball grid array represents a repeating pattern, many matches are returned when matching is applied without considering the neighborhood of the model. By defining a clutter region, the search can be restricted to specific instances of the model.
For matches found in a search image, edges within the clutter region increase the resulting clutter values. These are returned by find_shape_model, find_sized_shape_model, find_aniso_shape_model, find_shape_models, find_sized_shape_models, and find_aniso_shape_models in the parameter Score, following the common values measuring how much of the model is visible in the image. Note that the input parameter MinScore of those operators additionally expects information specifying the maximum clutter value up to which matches should be returned. For more information regarding the setting of MinScore, please refer to the respective operator reference.

To define the clutter region relative to the model contours, you need the region ClutterRegion and the transformation matrix HomMat2D that maps the model contours to the respective position where the object appears in an image. Typically, you obtain them by searching for a model instance in an image, e.g., with the operator find_shape_model. Then, the transformation matrix can be determined with the procedure get_hom_mat2d_from_matching_result using the respective output parameters of the search. The region ClutterRegion is specified within the same image. Note that ClutterRegion should contain the regions around the superfluous edges that are typical for all expected manifestations of the matches. We recommend that the clutter region is chosen larger than necessary when large scale ranges are searched. Furthermore, choosing the clutter region not too near to the expected model contours can increase the robustness.

The parameter ClutterContrast determines the contrast the edges in the clutter region must have in order to be counted as clutter. In many applications, the parameter Contrast, which has been used to create the shape model, is also a reasonable choice for ClutterContrast. ClutterContrast may not be smaller than the parameter MinContrast of the shape model, otherwise an error is raised at runtime. The polarity of the found clutter edges is ignored, i.e., bright objects on a dark background will yield the same clutter value as dark objects on a bright background, independent of the parameter Metric of the shape model. Please note that of all shape-based matching results, clutter values are affected the most when a variation of illumination occurs.

With GenParamName set to ‘clutter_border_mode’, the behavior of the clutter value can be influenced in cases where the clutter region of a found match is not entirely contained in the image domain. The corresponding values for ‘clutter_border_mode’ (GenParamValue) can be ‘clutter_border_average’ or ‘clutter_border_empty’.

- ‘clutter_border_average’:
  When GenParamValue is set to ‘clutter_border_average’ (default), the hidden part of the clutter region is assumed to be filled on average as is its visible part. If the clutter region is not visible at all, the clutter value of the found match is set to 0.0.

- ‘clutter_border_empty’:
  When GenParamValue is set to ‘clutter_border_empty’, the clutter region is assumed to be empty where it is not visible.

Note that GenParamValue set to ‘clutter_border_average’ results in higher clutter values.

The use of clutter parameters can be disabled and enabled by calling set_shape_model_param. For newly created shape models, the use of clutter parameters is disabled. After calling set_shape_model_clutter,
the use of clutter parameters is enabled. Depending on the activation status for the use of clutter parameters, the find operators, e.g., `find_shape_model`, expect a different number of entries in the input parameter `MinScore`. The set clutter parameters and the value of 'use_clutter' can be queried using the operator `get_shape_model_clutter`.

---

**Parameters**

- **ClutterRegion** (input_object)  
  Region where no clutter should occur.
- **ModelID** (input_control)  
  Handle of the model.
- **HomMat2D** (input_control)  
  Transformation matrix.
- **ClutterContrast** (input_control)  
  Minimum contrast of clutter in the search images.  
  Default value: 128
- **GenParamName** (input_control)  
  Parameter names.  
  List of values: `GenParamName ∈ {'clutter_border_mode'}`
- **GenParamValue** (input_control)  
  Parameter values.  
  List of values: `GenParamValue ∈ {'clutter_border_empty', 'clutter_border_average'}`

---

**Example**

* Create a shape model.
  ```
  read_image (ImageModel, '/bga_gap/bga_gap_01.png')
  gen_circle (ROI, 753.869, 551.624, 28.4027)
  reduce_domain (ImageModel, ROI, ImageReduced)
  create_aniso_shape_model (ImageReduced, 'auto', rad(0), rad(0), 'auto', 0.95, 1.05, 'auto', 0.95, 1.05, 'auto', 'auto', 'use_polarity', 'auto', 'auto', ModelID)
  *
  * Specify the clutter parameters.
    ```
    find_aniso_shape_model (ImageModel, ModelID, rad(0), rad(0), 0.95, 1.05, 0.95, 1.05, [0.83, MaxClutter], 0, 0.0, 'least_squares', [4, 3], 0.0, Row, Column, Angle, ScaleR, ScaleC, Score)
    get_hom_mat2d_from_matching_result (Row[0], Column[0], Angle[0], ScaleR[0], ScaleC[0], HomMat2D)
    gen_circle (ROI_0, 700.655, 548.666, 21.6273)
    gen_circle (ROI_1_0, 810.655, 550.611, 21.6273)
    union2 (ROI_0, ROI_1_0, ClutterRegion)
    *
    ClutterContrast := 12
    *
    * Set the clutter parameters into shape model.
      ```
      set_shape_model_clutter (ClutterRegion, ModelID, HomMat2D, ClutterContrast, [], [])
      *
    * Use the shape model to detect objects with a small amount of clutter
      ```
      read_image (Image, '/bga_gap/bga_gap_02.png')
      MaxClutter := 0.09
      find_aniso_shape_model (Image, ModelID, rad(0), rad(0), 0.95, 1.05, 0.95, 1.05, [0.83, MaxClutter], 0, 0.0, 'least_squares', [4, 3], 0.0, Row, Column, Angle, ScaleR, ScaleC, Score)
      *
      * Visualize the matches
        ```
        dev_display_shape_matching_results (ModelID, ['green', 'red'], Row, Column, Angle, ScaleR, ScaleC, 0)
        Clutter := Score[|Score|/2:|Score|-1]
        Score := Score[0:|Score|/2-1]
        dev_inspect_ctrl ([Score, Clutter])
        ```

---

**Result**

If the parameters are valid, the operator `set_shape_model_clutter` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

---

**Execution Information**

HALCON 20.11.0.0
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module
Matching

set_shape_model_metric ( Image : : ModelID, HomMat2D, Metric : )

Set the metric of a shape model that was created from XLD contours.

set_shape_model_metric changes the value of the parameter Metric that was selected during the creation of the shape model ModelID from XLD contours. For this, the polarity of the model edges is determined based on the image Image. The transformation that maps the model edges to the image position where the respective object appears is given in HomMat2D.

The parameter Metric determines the conditions under which the model is recognized later in the search image. If Metric = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If Metric = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of find_shape_model will increase slightly in this case.

It must be ensured that the object edges in the Image have the same (or inverse) polarity as the object edges in the image in which the object must be searched later. Especially, the object must not be occluded in the Image and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model edges will not represent the polarity of the object edges during the search. Note that only the polarity of the edges is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multichannel image is passed in Image, only the first channel will be used (and no error message will be returned).

The transformation defined by the matrix HomMat2D maps the model contours to the respective position where the object appears in the Image. It can be obtained by finding the object in the Image, e.g., with the operator find_shape_model and determining the respective transformation matrix with the procedure get_hom_mat2d_from_matching_result. The operator set_shape_model_metric ignores an origin that was set by set_shape_model_origin and always assumes (0,0) as the origin. Hence, when finding the object in the Image, all other operators must have the origin at the point (0,0). Therefore, set_shape_model_origin must be called with (0,0) as the origin.

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the shape model must be created from the XLD contours by setting the parameter Metric to 'ignore_local_polarity'. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image can be determined from the matching result. To
verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter \texttt{Metric} can be changed, e.g., to 'use\_polarity'. This leads to a faster and more robust recognition in the following images.

\vspace{0.5cm}

\begin{center}
\textbf{Attention}
\end{center}

\texttt{set\_shape\_model\_metric} can only be used with shape models that were created from XLD contours.

\vspace{0.5cm}

        HomMat2D)
endfor
\end{verbatim}
If the parameters are valid, the operator `set_shape_model_metric` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

### Possible Predecessors

- `create_shape_model_xld`
- `create_scaled_shape_model_xld`
- `create_aniso_shape_model_xld`

### Possible Successors

- `find_shape_model`
- `find_scaled_shape_model`
- `find_aniso_shape_model`

### See also

- `create_shape_model_xld`
- `create_scaled_shape_model_xld`
- `create_aniso_shape_model_xld`

### Module

Matching

---

**set_shape_model_origin**

Set the origin (reference point) of a shape model.

The operator `set_shape_model_origin` sets the origin (reference point) of the shape model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

### Parameters

- **ModelID** (input_control)  
  Handle of the model.
- **Row** (input_control)  
  Row coordinate of the origin of the shape model.
- **Column** (input_control)  
  Column coordinate of the origin of the shape model.

### Result

If the handle of the model is valid, the operator `set_shape_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:
• ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

area_center

Module

set_shape_model_param ( : : ModelID, GenParamName, GenParamValue : )

Set selected parameters of the shape model.

The operator set_shape_model_param sets the selected parameters GenParamName in the shape model ModelID. The following parameters can be modified:

'min_contrast'

Sets the minimum contrast of the object in the search images for the shape model ModelID. Thereby, the value of 'min_contrast' that was originally set, e.g. with create_shape_model, is overwritten for the shape model ModelID. Note that if the shape model ModelID was read from file and if this file should be changed as well, the shape model ModelID must again be written to file after the execution of the operator set_shape_model_param.

'timeout'

Sets the maximum runtime of the operators used to find the shape model ModelID (e.g. find_shape_model). This is especially useful in cases where a maximum cycle time has to be ensured. The 'timeout' must be given in milliseconds. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the 'timer_mode' set via set_system. Be aware that the runtime of the search increases by up to 10 percent with activated timeout. To disable the timeout you can either use a negative value or 'false'.

'border_shape_models'

This parameter determines whether the shape model ModelID to be found with, e.g., find_shape_model, may lie partially outside the image (i.e., whether they may cross the image border). The value of 'border_shape_models' can be 'true', 'false', or 'system'. The value 'system' is the default behavior and uses the system-wide used value that was set by set_system for the parameter 'border_shape_models'.

'use_clutter'

Disables or enables the use of clutter parameters for the shape model ModelID, which have been set previously using set_shape_model_clutter. The value of 'use_clutter' can be 'true' or 'false'. Note that the value of 'use_clutter' affects the expected number of entries in the input parameter MinScore of the find operators. Please refer to the documentation of the different find operators, e.g., find_shape_model.

For newly created shape models, the use of clutter parameters is disabled. After calling set_shape_model_clutter, the use of clutter parameters is enabled. Clutter parameters and the value of 'use_clutter' can be queried using get_shape_model_clutter.

'model_cache'

Disables or enables the use of an internal cache based on temporary memory that is used by a shape model when it executes, e.g., find_shape_model. The size of the cache depends on whether the find operation needs a big search space with many discretization steps. This means that a small AngleStep and ScaleStep and a big AngleExtent and a big range given by ScaleMin and ScaleMax result in a big memory consumption.
Switching the 'model_cache' off (by setting 'false') sometimes results in slightly longer execution times but constantly small memory footprint, particularly important in embedded applications. By default, this cache is switched on ('true').

--- Parameters

- **ModelID** (input_control) ........................................... shape_model ~ handle
  Handle of the model.

- **GenParamName** (input_control) ................................. attribute.name-array ~ string
  Parameter names.
  **List of values:** GenParamName ∈ ['min_contrast', 'timeout', 'border_shape_models', 'use_clutter', 'model_cache']

- **GenParamValue** (input_control) ............................ attribute.value-array ~ real / integer / string
  Parameter values.
  **List of values:** GenParamValue ∈ ['true', 'false', 'system']

--- Result

If the parameters are valid, the operator set_shape_model_param returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

--- Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Chapter 19

Matrix

19.1 Access

\texttt{get_diagonal_matrix} ( : : \texttt{MatrixID}, \texttt{Diagonal} : \texttt{VectorID} )

Get the diagonal elements of a matrix.
The operator \texttt{get_diagonal_matrix} generates a new matrix \texttt{Vector} and copies the diagonal elements of the \texttt{Matrix} to this new matrix. The \texttt{Matrix} is defined by the matrix handle \texttt{MatrixID}. The matrix \texttt{Vector} has one column and \( n \) rows, where \( n \) = number of diagonal elements. The operator returns the matrix handle \texttt{VectorID} of the matrix \texttt{Vector}. Access to the elements of the matrix is possible e.g. with the operator \texttt{get_full_matrix}.

If \texttt{Diagonal} = 0, the output of the \texttt{Vector} is the main diagonal of the \texttt{Matrix}.
Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix} \quad \text{Diagonal} = 0
\]

\[
\rightarrow \text{Vector} = \begin{bmatrix}
3.0 \\
7.0 \\
1.0
\end{bmatrix}
\]

If \texttt{Diagonal} is positive, the output \texttt{Vector} is the \texttt{Diagonal}-th super-diagonal of the \texttt{Matrix}.
Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix} \quad \text{Diagonal} = 2
\]

\[
\rightarrow \quad \text{Vector} = \begin{bmatrix}
-2.0 \\
6.0
\end{bmatrix}
\]

If \texttt{Diagonal} is negative, the \texttt{Diagonal}-th sub-diagonal of the \texttt{Matrix} is copied.
Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix} \quad \text{Diagonal} = -1
\]

\[
\rightarrow \quad \text{Vector} = \begin{bmatrix}
-5.0 \\
-4.0
\end{bmatrix}
\]
### Parameters

- **MatrixID** (input_control) ............................... matrix  \( \rightarrow \) handle  
  Matrix handle of the input matrix.
- **Diagonal** (input_control) .............................. integer  \( \rightarrow \) integer  
  Number of the desired diagonal.  
  Default value: 0  
  Suggested values: Diagonal \( \in \{-20, -10, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}\)
- **VectorID** (output_control) .............................. matrix  \( \rightarrow \) handle  
  Matrix handle containing the diagonal elements.

### Result

If the parameters are valid, the operator `get_diagonal_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Module

**Foundation**

---

### `get_full_matrix` (: : MatrixID : Values )

**Return all values of a matrix.**

The operator `get_full_matrix` returns the values of all elements of the Matrix given by the matrix handle `MatrixID`. The output parameter `Values` is a tuple of floating point numbers and contains all values in a row-major order, i.e., line by line.

Example:

\[
\text{Matrix} = \begin{bmatrix}
  3.0 & 1.0 & -2.0 \\
 -5.0 & 7.0 & 2.0 \\
 -9.0 & -4.0 & 1.0
\end{bmatrix} \rightarrow \text{Values} = [3.0, 1.0, -2.0, -5.0, 7.0, 2.0, -9.0, -4.0, 1.0]
\]

### Parameters

- **MatrixID** (input_control) ............................... matrix  \( \rightarrow \) handle  
  Matrix handle of the input matrix.
- **Values** (output_control) .............................. real(-array)  \( \rightarrow \) real  
  Values of the matrix elements.

### Result

If the parameters are valid, the operator `get_full_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

| clear_matrix |

See also

| set_full_matrix |

**Module**

Foundation

---

**get_sub_matrix** (: : MatrixID, Row, Column, RowsSub, ColumnsSub : MatrixSubID)

Get a sub-matrix of a matrix.

The operator `get_sub_matrix` generates a new matrix `MatrixSub` and copies to this matrix a part of the input `Matrix` defined by the matrix handle `Matrix`. The part of the `Matrix` is determined by the upper left corner `(Row,Column)` and the sub-matrix dimensions `(RowsSub,ColumnsSub)`. The operator returns the matrix handle `MatrixSubID` of the matrix `MatrixSub`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0 \\
\end{bmatrix}
\]

\[
\text{Row } = 0 \quad \text{Column } = 1 \quad \text{RowsSub } = 3 \quad \text{ColumnsSub } = 2
\]

\[
\Rightarrow \begin{bmatrix}
1.0 & -2.0 \\
7.0 & 2.0 \\
-4.0 & 1.0 \\
\end{bmatrix}
\]

**Attention**

The conditions \(0 \leq \text{Row} < \text{size of } \text{Matrix} \) in row direction, \(\text{Row} + \text{RowsSub} \leq \text{size of } \text{Matrix} \) in the row direction, \(0 \leq \text{Column} < \text{size of } \text{Matrix} \) in the column direction, and \(\text{Column} + \text{ColumnsSub} \leq \text{size of } \text{Matrix} \) in the column direction must be satisfied.

---

**Parameters**

- **MatrixID** (input_control) ➟ matrix handle
  - Matrix handle of the input matrix.
- **Row** (input_control) ➟ integer
  - Upper row position of the sub-matrix in the input matrix.
  - **Default value:** 0
  - **Suggested values:** `Row ∈ \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}`
  - **Restriction:** `Row >= 0`
- **Column** (input_control) ➟ integer
  - Left column position of the sub-matrix in the input matrix.
  - **Default value:** 0
  - **Suggested values:** `Column ∈ \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}`
  - **Restriction:** `Column >= 0`
- **RowsSub** (input_control) ➟ integer
  - Number of rows of the sub-matrix.
  - **Default value:** 1
  - **Suggested values:** `RowsSub ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}`
  - **Restriction:** `RowsSub >= 1`
\[ \text{ColumnsSub} \text{ (input\_control) } \] \hspace{3em} \text{integer} \leftarrow \text{integer} \\
Number of columns of the sub-matrix.

**Default value:** 1  
**Suggested values:** ColumnsSub \( \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\} 

**Restriction:** ColumnsSub \( \geq 1 \)

\[ \text{MatrixSubID} \text{ (output\_control) } \] \hspace{3em} \text{matrix} \leftarrow \text{handle} \\
Matrix handle of the sub-matrix.

---

**Result**

If the parameters are valid, the operator \text{get\_sub\_matrix} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

---

**Execution Information**

\text{get\_value\_matrix} \( ( \text{: : MatrixID, Row, Column : Value } ) \)

*Return one ore more elements of a matrix.*

The operator \text{get\_value\_matrix} returns the values of one ore more elements of the \text{Matrix} as a tuple of floating point numbers. The \text{Matrix} is given by the matrix handle \text{MatrixID}. The row coordinates of the elements of the \text{Matrix} are determined by the tuple \text{Row}, the column coordinates by the tuple \text{Column}.

**Example:**

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix} \quad \text{Row} = [0, 2, 1] \quad \text{Column} = [1, 0, 3] \\
\rightarrow \quad \text{Value} = [1.0, -9.0, 6.0]
\]

---

**Parameters**

- \text{MatrixID} \text{ (input\_control) } \hspace{3em} \text{matrix} \leftarrow \text{handle} \\
Matrix handle of the input matrix.

- \text{Row} \text{ (input\_control) } \hspace{3em} \text{integer\(-array\) } \leftarrow \text{integer} \\
Row numbers of matrix elements to be returned. 

**Default value:** 0  
**Suggested values:** Row \( \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\} 

**Restriction:** Row \( \geq 0 \)

- \text{Column} \text{ (input\_control) } \hspace{3em} \text{integer\(-array\) } \leftarrow \text{integer} \\
Column numbers of matrix elements to be returned. 

**Default value:** 0  
**Suggested values:** Column \( \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\} 

**Restriction:** Column \( \geq 0 \)

- \text{Value} \text{ (output\_control) } \hspace{3em} \text{real\(-array\) } \leftarrow \text{real} \\
Values of indicated matrix elements.
Result

If the parameters are valid, the operator `get_value_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

- `create_matrix`

Possible Successors

- `clear_matrix`

See also

- `set_value_matrix`

Module

Foundation

```plaintext
set_diagonal_matrix ( : : MatrixID, VectorID, Diagonal : )
```

Set the diagonal elements of a matrix.

The operator `set_diagonal_matrix` overwrite(s) the diagonal elements of the `Matrix` with the elements of the matrix `Vector`. The matrices are defined by their matrix handles `MatrixID` and `VectorID`. The matrix `Vector` must have one column and one row, one column and one row or one column and `n` rows. `n` is the number of elements to be set in the `Matrix` (see below). If the matrix `Vector` has one column and one row, i.e., the matrix has one value, each element of the diagonal of the `Matrix` is overwritten by this value. Otherwise, the diagonal is overwritten by the elements of the matrix `Vector`.

If `Diagonal` = 0, the main diagonal of the `Matrix` is overwritten. The number `n = min(number of rows of Matrix, number of columns of Matrix)`.

Example 1:

```
Matrix = [ 0.0 0.0 0.0 0.0 ]
    [ 0.0 0.0 0.0 0.0 ]
    [ 0.0 0.0 0.0 0.0 ]
Vector = [ 3.0 7.0 1.0 ]
Diagonal = 0

    → Matrix = [ 3.0 0.0 0.0 0.0 ]
              [ 0.0 7.0 0.0 0.0 ]
              [ 0.0 0.0 1.0 0.0 ]
```

Example 2:

```
Matrix = [ 0.0 0.0 0.0 0.0 ]
    [ 0.0 0.0 0.0 0.0 ]
    [ 0.0 0.0 0.0 0.0 ]
Vector = [ 3.0 ]
Diagonal = 0

    → Matrix = [ 3.0 0.0 0.0 0.0 ]
              [ 0.0 3.0 0.0 0.0 ]
              [ 0.0 0.0 3.0 0.0 ]
```

If `Diagonal` is positive, the `Diagonal`-th super-diagonal of `Matrix` is overwritten. For the example 1 the number `n = min(number of rows of Matrix, parameter Diagonal)`.

Example 1:
Matrix = \[
\begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
\end{bmatrix}
\] Vector = [ -2.0, 6.0 ] Diagonal = 2

Example 2:
Matrix = \[
\begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
\end{bmatrix}
\] Vector = [ -2.0 ] Diagonal = 2

\[
\rightarrow \text{Matrix} = \begin{bmatrix}
0.0 & 0.0 & -2.0 & 0.0 \\
0.0 & 0.0 & 0.0 & -2.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
\end{bmatrix}
\]

If Diagonal is negative, the Diagonal-th sub-diagonal of Matrix is overwritten. For the example 1 the number \( n = \min(\text{number of columns of Matrix}, \text{parameter Diagonal}) \). For the example 2 the number \( n = \min(\text{number of rows of Matrix}, \text{number of columns of Matrix}) \).

Example 1:
Matrix = \[
\begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
\end{bmatrix}
\] Vector = [ -5.0, -4.0 ] Diagonal = -1

\[
\rightarrow \text{Matrix} = \begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
-5.0 & 0.0 & 0.0 & 0.0 \\
0.0 & -4.0 & 0.0 & 0.0 \\
\end{bmatrix}
\]

Example 2:
Matrix = \[
\begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 & 0.0 \\
\end{bmatrix}
\] Vector = [ -5 ] Diagonal = -1

\[
\rightarrow \text{Matrix} = \begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0 \\
-5.0 & 0.0 & 0.0 & 0.0 \\
0.0 & -5.0 & 0.0 & 0.0 \\
\end{bmatrix}
\]

### Parameters
- **MatrixID** (input_control) 
  Matrix handle of the input matrix.
- **VectorID** (input_control) 
  Matrix handle containing the diagonal elements to be set.
- **Diagonal** (input_control) 
  Position of the diagonal.
  Default value: 0
  Suggested values: Diagonal \( \in \{-20, -10, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\} \)

### Result
If the parameters are valid, the operator `set_diagonal_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
19.1. ACCESS

• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:
• MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_matrix

Possible Successors

set_full_matrix (: : MatrixID, Values : )

Set all values of a matrix.

The operator set_full_matrix sets all elements of the input Matrix defined by the matrix handle MatrixID. The values of the parameter Values can be a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically. The parameter Values must contain all values in a row-major order, i.e., stored line by line. In addition, the number of elements in Values must be 1 or identical to the number of all elements of the matrix.

Note: The same result can be reached with the operator create_matrix. The advantage by using the operator set_full_matrix is to recycle a matrix that is no longer needed. Thus, the runtime of the operation takes fewer time.

Example 1:

Matrix = 
\[
\begin{bmatrix}
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Values = [3, 1, -2, -5, 7, 2, -9, -4, 1]

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\] →

Example 2:

Matrix = 
\[
\begin{bmatrix}
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Values = [7]

\[
\begin{bmatrix}
7.0 & 7.0 & 7.0 \\
7.0 & 7.0 & 7.0 \\
7.0 & 7.0 & 7.0
\end{bmatrix}
\] →

Parameters

MatrixID (input_control) ...................................................... matrix ～ handle
Matrix handle of the input matrix.

Values (input_control) ...................................................... number(-array) ～ real / integer
Values to be set.
Result

If the parameters are valid, the operator `set_full_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

```plaintext
def set_sub_matrix( : : MatrixID, MatrixSubID, Row, Column : )
```

Set a sub-matrix of a matrix.

The operator `set_sub_matrix` *overwrites* a part of the Matrix with the matrix `MatrixSub`. The input matrices are defined by the matrix handles `MatrixID` and `MatrixSubID`. The parameters `Row` and `Column` determine the position of the upper left corner of the sub-matrix `MatrixSub` in `Matrix`.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 0.0 & 9.0 & 1.0 \\
-5.0 & 3.0 & 1.0 & 6.0 \\
-9.0 & 0.0 & 1.0 & -1.0
\end{bmatrix}
\]

\[
\text{MatrixSub} = \begin{bmatrix}
1.0 & -2.0 \\
7.0 & 2.0 \\
-4.0 & 1.0
\end{bmatrix}
\]

\[
\text{Row} = 0 \quad \text{Column} = 1
\]

\[
\Rightarrow \text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0
\end{bmatrix}
\]

Attention

- The conditions \(0 \leq \text{Row} < \text{size of matrix} \text{Matrix} \text{ in the row direction,} \text{ Row} + \text{ size of matrix} \text{MatrixSub} \text{ in the row direction} \leq \text{size of matrix} \text{Matrix} \text{ in the row direction,} 0 \leq \text{Column} < \text{size of matrix} \text{Matrix} \text{ in the column direction,} \text{ Column} + \text{ size of matrix} \text{MatrixSub} \text{ in the columns direction} \leq \text{size of matrix} \text{Matrix} \text{ in the column direction} \) must be satisfied.

Parameters

- `MatrixID` (input_control) ... `Matrix handle of the input matrix.`
- `MatrixSubID` (input_control) ... `Matrix handle of the input sub-matrix.`
- `Row` (input_control) ... `Upper row position of the sub-matrix in the matrix.`

Default value: 0

Suggested values: \(\text{Row} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}\)

Restriction: \(\text{Row} \geq 0\)
19.1. ACCESS

\[ \text{Column} \ (\text{input_control}) \quad \text{integer} \rightarrow \text{integer} \]
Left column position of the sub-matrix in the matrix.

**Default value:** 0

**Suggested values:** Column ∈ \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}

**Restriction:** Column \(\geq 0\)

**set_value_matrix** ( : : MatrixID, Row, Column, Value : )

Set one or more elements of a matrix.

The operator **set_value_matrix** sets the values of the elements of the input **Matrix** at the positions \((\text{Row, Column})\) to the values specified by **Value**. The values can be a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically. The number of values of **Value** must match the number of elements of **Row** and **Column**. In addition, the conditions \(0 \leq \text{Row} < \text{size of Matrix}\) in the row direction and \(0 \leq \text{Column} < \text{size of Matrix}\) in the column direction must be satisfied. The **Matrix** is defined by the matrix handle **MatrixID**.

Example:

\[
\begin{bmatrix}
3.0 & 0.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & -2.0 \\
8.0 & -4.0 & 1.0 & -1.0 \\
\end{bmatrix}
\]

\(\text{Row} = [0, 2, 1]\)  \(\text{Column} = [1, 0, 3]\)  \(\text{Value} = [1, -9, 6]\)

\(\Rightarrow\) \(\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 & -2.0 & 1.0 \\
-5.0 & 7.0 & 2.0 & 6.0 \\
-9.0 & -4.0 & 1.0 & -1.0 \\
\end{bmatrix}\)
Parameters

- **MatrixID** (input_control) .......................... matrix  \( \rightarrow \) handle
  Matrix handle of the input matrix.

- **Row** (input_control) .......................... integer(-array)  \( \rightarrow \) integer
  Row numbers of the matrix elements to be modified.
  Default value: 0
  Suggested values: \( \text{Row} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\} \)
  Restriction: \( \text{Row} \geq 0 \)

- **Column** (input_control) .................................. integer(-array)  \( \rightarrow \) integer
  Column numbers of the matrix elements to be modified.
  Default value: 0
  Suggested values: \( \text{Column} \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\} \)
  Restriction: \( \text{Column} \geq 0 \)

- **Value** (input_control) .......................... number(-array)  \( \rightarrow \) real / integer
  Values to be set in the indicated matrix elements.
  Default value: 0
  Suggested values: \( \text{Value} \in \{0, 1, -1\} \)

Result

If the parameters are valid, the operator `set_value_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Module

19.2 Arithmetic

```
abs_matrix ( : : MatrixID : MatrixAbsID )
```

Compute the absolute values of the elements of a matrix.

The operator `abs_matrix` computes the absolute values of all elements of the input `Matrix` given by the matrix handle `MatrixID`. A new matrix `MatrixAbs` is generated with the result. The operator returns the matrix handle `MatrixAbsID` of the matrix `MatrixAbs`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[ \text{MatrixAbs}_{ij} = |\text{Matrix}_{ij}|. \]

Example:
Matrix \[= \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \rightarrow \text{MatrixAbs} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix} \]

Parameters

- **MatrixID (input_control)**
  - matrix \(\Rightarrow\) handle
  - Matrix handle of the input matrix.

- **MatrixAbsID (output_control)**
  - matrix \(\Rightarrow\) handle
  - Matrix handle with the absolute values of the input matrix.

Result

If the parameters are valid, the operator \text{abs_matrix} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

**abs_matrix_mod ( : : MatrixID : )**

Compute the absolute values of the elements of a matrix.

The operator \text{abs_matrix_mod} computes the absolute values of all elements of the input Matrix given by the matrix handle **MatrixID**. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator **get_full_matrix**. The formula for the calculation of the result is:

\[ \text{Matrix}_{ij} = |\text{Matrix}_{ij}|. \]

Example:

\[
\begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \rightarrow \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}
\]

Parameters

- **MatrixID (input_control)**
  - matrix \(\Rightarrow\) handle
  - Matrix handle of the input matrix.

Result

If the parameters are valid, the operator \text{abs_matrix_mod} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

| add_matrix ( : : MatrixAID, MatrixBID : MatrixSumID ) |

Add two matrices.

The operator add_matrix computes the sum of the input matrices MatrixA and MatrixB given by the matrix handles MatrixAID and MatrixBID. Both matrices must have identical dimensions. A new matrix MatrixSum is generated with the result. The operator returns the matrix handle MatrixSumID of the matrix MatrixSum. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[
\text{MatrixSum} = \text{MatrixA} + \text{MatrixB}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\quad \begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 5.0 \\
2.0 & -4.0 & 7.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
5.0 & 9.0 & -5.0 \\
-9.0 & 6.0 & 7.0 \\
-7.0 & -8.0 & 8.0
\end{bmatrix}
\]

Parameters

la MatrixAID (input_control) ........................................matrix \rightarrow \text{handle}
Matrix handle of the input matrix A.

la MatrixBID (input_control) ........................................matrix \rightarrow \text{handle}
Matrix handle of the input matrix B.

la MatrixSumID (output_control) ......................................matrix \rightarrow \text{handle}
Matrix handle with the sum of the input matrices.

Result

If the parameters are valid, the operator add_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

### div_element_matrix

Divide matrices element-by-element.

The operator `div_element_matrix` divides the two matrices `MatrixA` and `MatrixB` element-by-element. The matrices are given by the matrix handles `MatrixAID` and `MatrixBID`. It is required that both input matrices have identical dimensions. The new created output `MatrixDiv` contains the result. The operator returns the matrix handle `MatrixDivID` of the matrix `MatrixDiv`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{MatrixDiv}_{ij} = \frac{\text{MatrixA}_{ij}}{\text{MatrixB}_{ij}}.
\]

**Example:**

\[
\begin{align*}
\text{MatrixA} &= \begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0 \\
\end{bmatrix}, \\
\text{MatrixB} &= \begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 4.0 \\
-2.0 & -4.0 & 2.0 \\
\end{bmatrix} \\
\rightarrow \text{MatrixDiv} &= \begin{bmatrix}
2.0 & 1.0 & 0.0 \\
1.5 & -7.0 & 0.5 \\
4.5 & -1.0 & 0.5 \\
\end{bmatrix}
\end{align*}
\]

**Parameters**

- **MatrixAID** (input_control) .................................................. matrix  \(\sim \) handle
  - Matrix handle of the input matrix A.
- **MatrixBID** (input_control) .................................................. matrix  \(\sim \) handle
  - Matrix handle of the input matrix B.
- **MatrixDivID** (output_control) ............................................. matrix  \(\sim \) handle
  - Matrix handle with the divided values of input matrices.

**Result**

If the parameters are valid, the operator `div_element_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

HALCON/HDevelop Reference Manual, 2020-11-10
Divide matrices element-by-element.

The operator `div_element_matrix_mod` divides the two matrices `MatrixA` and `MatrixB` element-by-element. The matrices are given by the matrix handles `MatrixAID` and `MatrixBID`. It is required that both input matrices have identical dimensions. The input matrix `MatrixA` is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
MatrixA_{ij} = MatrixA_{ij} / MatrixB_{ij}.
\]

Example:

\[
MatrixA = \begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0
\end{bmatrix}
\]
\[
MatrixB = \begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 4.0 \\
-2.0 & -4.0 & 2.0
\end{bmatrix}
\]
\[
\Rightarrow MatrixA = \begin{bmatrix}
2.0 & 1.0 & 0.0 \\
1.5 & -7.0 & 0.5 \\
4.5 & -1.0 & 0.5
\end{bmatrix}
\]

**Parameters**

- `MatrixAID` (input_control, matrix) ➔ handle
  Matrix handle of the input matrix A.
- `MatrixBID` (input_control, matrix) ➔ handle
  Matrix handle of the input matrix B.

**Result**

If the parameters are valid, the operator `div_element_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixAID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
Possible Successors
get_full_matrix, get_value_matrix

Alternatives
div_element_matrix
See also
mult_element_matrix, mult_element_matrix_mod, scale_matrix, scale_matrix_mod

Module

invert_matrix ( : : MatrixID, MatrixType, Epsilon : MatrixInvID )

Invert a matrix.

The operator invert_matrix computes the inverse of the Matrix defined by the matrix handle MatrixID. A new matrix MatrixInv is generated with the result and the matrix handle MatrixInvID of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

For Epsilon = 0, the inverse is computed. The type of the Matrix can be selected via MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'tridiagonal' for tridiagonal, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices.

Example 1:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
5.0 & 5.0 & 7.0 \\
\end{bmatrix}
\]

MatrixType = 'general' Epsilon = 0

\[
\begin{bmatrix}
-1.25 & 1.50 & -0.75 \\
-0.50 & 2.00 & -1.50 \\
1.25 & -2.50 & 1.75 \\
\end{bmatrix}
\]

Example 2:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 2.0 & 6.0 \\
0 & 0 & 10.0 \\
\end{bmatrix}
\]

MatrixType = 'upper_triangular' Epsilon = 0

\[
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10 \\
\end{bmatrix}
\]

Example 3:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 0 & 10.0 \\
0 & 2.0 & 6.0 \\
\end{bmatrix}
\]

MatrixType = 'permuted_upper_triangular' Epsilon = 0

\[
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10 \\
\end{bmatrix}
\]

For Epsilon > 0, the pseudo inverse is computed using a singular value decomposition (SVD). During the computation, all singular values less than the value Epsilon \times the largest singular value are set to 0. For these values no internal division is done to prevent a division by zero. If a square matrix is computed with the SVD algorithm the computation takes more time. The type of the matrix must be set to MatrixType = 'general'.

Example:
Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 5.0 \\
-5.0 & 7.0 & 2.0 & -6.0 \\
-9.0 & -4.0 & 1.0 & 4.0
\end{bmatrix}
\]
MatrixType = 'general'    \[\text{Epsilon} = 2.2204\times10^{-16}\]
\[
\rightarrow \text{MatrixInv} = \begin{bmatrix}
-0.0021 & -0.0482 & -0.0813 \\
0.1435 & 0.1137 & -0.0137 \\
-0.0519 & -0.0015 & 0.0028 \\
0.1518 & 0.0056 & 0.0526
\end{bmatrix}
\]

Note: The relative accuracy of the floating point representation of the used data type (double) is \[\text{Epsilon} = 2.2204\times10^{-16}\].

It should be also noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

Attention
For MatrixType = 'symmetric', 'positive_definite', or 'upper_triangular' the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixType = 'lower_triangular' the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For MatrixType = 'tridiagonal', only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

Parameters

\[\begin{align*}
\text{MatrixID} & \ (\text{input_control}) \quad \text{matrix handle of the input matrix.} \\
\text{MatrixType} & \ (\text{input_control}) \quad \text{string} \quad \text{The type of the input matrix.} \\
\text{Default value}: & \ 'general' \\
\text{List of values}: & \ \text{MatrixType} \in \{\text{'general'}, \text{'symmetric'}, \text{'positive_definite'}, \text{'tridiagonal'}, \text{'upper_triangular'}, \\
& \ \text{'permuted_upper_triangular'}, \text{'lower_triangular'}, \text{'permuted_lower_triangular'}\} \\
\text{Epsilon} & \ (\text{input_control}) \quad \text{real} \quad \text{Type of inversion.} \\
\text{Default value}: & \ 0.0 \\
\text{Suggested values}: & \ \text{Epsilon} \in [0.0, 2.2204\times10^{-16}] \\
\text{MatrixInvID} & \ (\text{output_control}) \quad \text{matrix handle with the inverse matrix.}
\end{align*}\]

Result
If the parameters are valid, the operator invert_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

\begin{itemize}
\item Multithreading type: reentrant (runs in parallel with non-exclusive operators).
\item Multithreading scope: global (may be called from any thread).
\item Processed without parallelization.
\end{itemize}
References

invert_matrix_mod ( : : MatrixID, MatrixType, Epsilon : )

Invert a matrix.
The operator invert_matrix_mod computes the inverse of the Matrix defined by the matrix handle MatrixID. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

For Epsilon = 0, the inverse is computed. The type of the Matrix can be selected via MatrixType. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'tridiagonal' for tridiagonal, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices.

Example 1:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
5.0 & 5.0 & 7.0
\end{bmatrix}
\]
MatrixType = 'general'  Epsilon = 0

\[
\begin{bmatrix}
-1.25 & 1.50 & -0.75 \\
-0.50 & 2.00 & -1.50 \\
1.25 & -2.50 & 1.75
\end{bmatrix}
\]

Example 2:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 2.0 & 6.0 \\
0 & 0 & 10.0
\end{bmatrix}
\]
MatrixType = 'upper_triangular'  Epsilon = 0

\[
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10
\end{bmatrix}
\]

Example 3:

\[
\begin{bmatrix}
1.0 & 3.0 & 3.0 \\
0 & 0 & 10.0 \\
0 & 2.0 & 6.0
\end{bmatrix}
\]
MatrixType = 'permuted_upper_triangular'  Epsilon = 0

\[
\begin{bmatrix}
1.00 & -1.50 & 0.60 \\
0 & 0.50 & -0.30 \\
0 & 0 & 0.10
\end{bmatrix}
\]

For Epsilon > 0, the pseudo inverse is computed using a singular value decomposition (SVD). During the computation, all singular values less than the value Epsilon \times the largest singular value are set to 0. For these values no internal division is done to prevent a division by zero. If a square matrix is computed with the SVD algorithm the computation takes more time. The type of the matrix must be set to MatrixType = 'general'.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 & 5.0 \\
-5.0 & 7.0 & 2.0 & -6.0 \\
-9.0 & -4.0 & 1.0 & 4.0
\end{bmatrix}
\]
MatrixType = 'general'  Epsilon = 2.2204e-16
→ Matrix = 
\[
\begin{bmatrix}
-0.0021 & -0.0482 & -0.0813 \\
0.1435 & 0.1137 & -0.0137 \\
-0.0519 & -0.0015 & 0.0028 \\
0.1518 & 0.0056 & 0.0526
\end{bmatrix}
\]

Note: The relative accuracy of the floating point representation of the used data type (double) is \textbf{Epsilon} = 2.2204e-16.

It should be also noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

\[\text{Attention}\]

For \texttt{MatrixType} = 'symmetric', 'positive_definite', or 'upper_triangular' the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For \texttt{MatrixType} = 'lower_triangular' the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For \texttt{MatrixType} = 'tridiagonal', only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

\texttt{invert_matrix_mod} modifies the content of an already existing matrix.

\[\text{Parameters}\]

\[\text{MatrixID} \text{ (input\_control)} \quad \text{Matrix handle of the input matrix.}\]
\[\text{MatrixType} \text{ (input\_control)} \quad \text{string} \quad \text{The type of the input matrix.}\]
\[\text{Default value:} \quad \text{'general'}\]
\[\text{List of values:} \text{MatrixType} \in \{\text{'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}\}\]
\[\text{Epsilon} \text{ (input\_control)} \quad \text{real} \quad \text{Type of inversion.}\]
\[\text{Default value:} \quad 0.0\]
\[\text{Suggested values:} \quad \text{Epsilon} \in \{0.0, 2.2204e-16\}\]

\[\text{Result}\]

If the parameters are valid, the operator \texttt{invert_matrix_mod} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

\[\text{Execution Information}\]

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- \texttt{MatrixID}

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

**mult_element_matrix** ( : : MatrixAID, MatrixBID : MatrixMultID )

Multiply matrices element-by-element.
The operator `mult_element_matrix` multiplies the two matrices `MatrixA` and `MatrixB` element-by-element. The matrices are defined by the matrix handles `MatrixAID` and `MatrixBID`. It is required that both input matrices have identical dimensions. A new matrix `MatrixMult` is generated with the result. The operator returns the matrix handle `MatrixMultID` of the matrix `MatrixMult`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[ \text{MatrixMult}_{ij} = \text{MatrixA}_{ij} \cdot \text{MatrixB}_{ij}. \]

Example:

\[
\begin{bmatrix}
4.0 & 8.0 & 0.0 \\
-6.0 & 7.0 & 2.0 \\
-9.0 & 4.0 & 1.0
\end{bmatrix}
\begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 4.0 \\
-2.0 & -4.0 & 2.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
8.0 & 64.0 & 0.0 \\
24.0 & -7.0 & 8.0 \\
18.0 & -16.0 & 2.0
\end{bmatrix}
\]

Parameters

- **MatrixAID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle of the input matrix A.
- **MatrixBID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix handle of the input matrix B.
- **MatrixMultID** (output_control) . . . . . . . . . . . . . . . . . . . . . . . matrix handle with the multiplied values of the input matrices.

Result

If the parameters are valid, the operator `mult_element_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

Foundation
**\textbf{Multiply two matrices.}**

The operator \texttt{mult_matrix} computes the product of the input matrices \texttt{MatrixA} and \texttt{MatrixB} defined by the matrix handles \texttt{MatrixAID} and \texttt{MatrixBID}. A new matrix \texttt{MatrixMult} is generated with the result. The operator returns the matrix handle \texttt{MatrixMultID} of the matrix \texttt{MatrixMult}. Access to the elements of the matrix is possible e.g. with the operator \texttt{get_full_matrix}. If desired, one or both input matrices will be transposed for the multiplication.

The type of multiplication can be selected via \texttt{MultType}:

\textbf{’AB’}: The matrices \texttt{MatrixA} and \texttt{MatrixB} will not be transposed. Therefore, the formula for the calculation of the result is:

\[
\text{MatrixMult} = \text{MatrixA} \cdot \text{MatrixB}.
\]

The number of columns of the matrix \texttt{MatrixA} must be identical to the number of rows of the matrix \texttt{MatrixB}.

Example:

\[
\begin{array}{ccc}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{array}
\]

\[
\begin{array}{ccc}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{array}
\]

\[
\rightarrow \text{MatrixMult} = \begin{array}{ccc}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{array}
\]

\textbf{’ATB’}: The matrix \texttt{MatrixA} will be transposed. The matrix \texttt{MatrixB} will not be transposed. Therefore, the formula for the calculation of the result is:

\[
\text{MatrixMult} = \text{MatrixA}^T \cdot \text{MatrixB}.
\]

The number of rows of the matrix \texttt{MatrixA} must be identical to the number of rows of the matrix \texttt{MatrixB}.

Example:

\[
\begin{array}{ccc}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{array}
\]

\[
\begin{array}{ccc}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{array}
\]

\[
\rightarrow \text{MatrixMult} = \begin{array}{ccc}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{array}
\]

\textbf{’ABT’}: The matrix \texttt{MatrixA} will not be transposed. The matrix \texttt{MatrixB} will be transposed. Therefore, the formula for the calculation of the result is:

\[
\text{MatrixMult} = \text{MatrixA} \cdot \text{MatrixB}^T.
\]

The number of columns of the matrix \texttt{MatrixA} must be identical to the number of columns of the matrix \texttt{MatrixB}.

Example:

\[
\begin{array}{ccc}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{array}
\]

\[
\begin{array}{ccc}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{array}
\]

\[
\rightarrow \text{MatrixMult} = \begin{array}{ccc}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{array}
\]
'ATBT': The matrix MatrixA and the matrix MatrixB will be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixMult} = \text{MatrixA}^T \cdot \text{MatrixB}^T. \]

The number of rows of the matrix MatrixA must be identical to the number of columns of the matrix MatrixB.

Example:

\[
\begin{bmatrix}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{bmatrix}
\begin{bmatrix}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{bmatrix}
\]

\[ \Rightarrow \quad \text{MatrixMult} = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix} \]

Parameters

- **MatrixAID** (input_control) ............ matrix handle
  Matrix handle of the input matrix A.

- **MatrixBID** (input_control) ............ matrix handle
  Matrix handle of the input matrix B.

- **MultType** (input_control) ............ string
  Type of the input matrices.
  Default value: 'AB'
  List of values: MultType ∈ {'AB', 'ATB', 'ABT', 'ATBT'}

- **MatrixMultID** (output_control) ........ matrix handle
  Matrix handle of the multiplied matrices.

Result

If the parameters are valid, the operator mult_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Multiply two matrices.**

The operator `mult_matrix` computes the product of the input matrices `MatrixA` and `MatrixB` defined by the matrix handles `MatrixAID` and `MatrixBID`. The input matrix `MatrixA` is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. If desired, one or both input matrices will be transposed for the multiplication.

The type of multiplication can be selected via `MultType`:

'**AB**': The matrices `MatrixA` and `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

\[
MatrixA = MatrixA \cdot MatrixB.
\]

The number of columns of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

\[
MatrixA = \begin{bmatrix}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{bmatrix}
\]
\[
MatrixB = \begin{bmatrix}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{bmatrix}
\]
\[
\Rightarrow MatrixA = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

'**ATB**': The matrix `MatrixA` will be transposed. The matrix `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

\[
MatrixA = MatrixA^T \cdot MatrixB.
\]

The number of rows of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

\[
MatrixA = \begin{bmatrix}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{bmatrix}
\]
\[
MatrixB = \begin{bmatrix}
3.0 & -3.0 & 1.0 & 1.0 \\
2.0 & -1.0 & -2.0 & -1.0
\end{bmatrix}
\]
\[
\Rightarrow MatrixA = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

'**ABT**': The matrix `MatrixA` will not be transposed. The matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

\[
MatrixA = MatrixA \cdot MatrixB^T.
\]

The number of columns of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

\[
MatrixA = \begin{bmatrix}
3.0 & -3.0 \\
2.0 & -5.0 \\
-3.0 & 2.0
\end{bmatrix}
\]
\[
MatrixB = \begin{bmatrix}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{bmatrix}
\]
\[
\Rightarrow MatrixA = \begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]
''ATBT'': The matrix MatrixA and the matrix MatrixB will be transposed. Therefore, the formula for the calculation of the result is:

\[ \text{MatrixA} = \text{MatrixA}^T \cdot \text{MatrixB}^T. \]

The number of rows of the matrix MatrixA must be identical to the number of columns of the matrix MatrixB.

Example:

\[
\begin{bmatrix}
3.0 & 2.0 & -3.0 \\
-3.0 & -5.0 & 2.0
\end{bmatrix}
\begin{bmatrix}
3.0 & 2.0 \\
-3.0 & -1.0 \\
1.0 & -2.0 \\
1.0 & -1.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
3.0 & -6.0 & 9.0 & 6.0 \\
-4.0 & -1.0 & 12.0 & 7.0 \\
-5.0 & 7.0 & -7.0 & -5.0
\end{bmatrix}
\]

Parameters

- MatrixAID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix \(\Rightarrow\) handle
  Matrix handle of the input matrix A.

- MatrixBID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix \(\Rightarrow\) handle
  Matrix handle of the input matrix B.

- MultType (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string \(\Rightarrow\) string
  Type of the input matrices.

  Default value: 'AB'

  List of values: MultType \(\in\) \{'AB', 'ATB', 'ABT', 'ATBT'\}

Result

If the parameters are valid, the operator mult_matrix_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixAID

Compute the power functions of the elements of a matrix.

The operator `pow_element_matrix` computes the power of all elements of the input matrix with the elements of the input matrix `MatrixExp`. The input matrices `Matrix` and `MatrixExp` are defined by the matrix handles `MatrixID` and `MatrixExpID`. Both matrices must have identical dimensions. A new matrix `MatrixPow` is generated with the result. The operator returns the matrix handle `MatrixPowID` of the matrix `MatrixPow`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[ \text{MatrixPow}_{ij} = \text{Matrix}_{ij} \text{MatrixExp}_{ij} \]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
1.0 & 2.0 & 2.0 \\
2.0 & 0.0 & 3.0 \\
0.5 & 3.0 & 1.0
\end{bmatrix}
\]

\[\rightarrow \begin{bmatrix}
3.0 & 1.0 & 4.0 \\
25.0 & 1.0 & 8.0 \\
3.0 & 64.0 & 1.0
\end{bmatrix}\]

Parameters

\[\begin{align*}
\text{MatrixID} & : \text{Matrix handle of the input matrix of the base.} \\
\text{MatrixExpID} & : \text{Matrix handle of the input matrix with exponents.} \\
\text{MatrixPowID} & : \text{Matrix handle with the raised power of the input matrix.}
\end{align*}\]

Result

If the parameters are valid, the operator `pow_element_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Compute the power functions of the elements of a matrix.

HALCON/HDevelop Reference Manual, 2020-11-10
The operator `pow_element_matrix_mod` computes the power of all elements of the input matrix `Matrix` with the elements of the input matrix `MatrixExp`. The input matrices `Matrix` and `MatrixExp` are defined by the matrix handles `MatrixID` and `MatrixExpID`. Both matrices must have identical dimensions. The input `Matrix` is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[ Matrix_{ij} = Matrix_{ij}^{\text{MatrixExp}_{ij}}. \]

Example:

\[
\begin{pmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{pmatrix}
\]

\[
\begin{pmatrix}
1.0 & 2.0 & 2.0 \\
2.0 & 0.0 & 3.0 \\
0.5 & 3.0 & 1.0
\end{pmatrix}
\]

\[ \rightarrow \]

\[
\begin{pmatrix}
3.0 & 1.0 & 4.0 \\
25.0 & 1.0 & 8.0 \\
3.0 & 64.0 & 1.0
\end{pmatrix}
\]

**Parameters**

- `MatrixID` (input_control) ~ handle matrix handle of the input matrix of the base.
- `MatrixExpID` (input_control) ~ handle matrix handle of the input matrix with exponents.

If the parameters are valid, the operator `pow_element_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

- `create_matrix`

**Possible Successors**

- `get_full_matrix`, `get_value_matrix`

**Alternatives**

- `pow_element_matrix`, `pow_scalar_element_matrix`, `pow_scalar_element_matrix_mod`

**See also**

- `sqrt_matrix`, `sqrt_matrix_mod`

**Module**

- `pow_matrix ( : : MatrixID, MatrixType, Power : : MatrixPowID )`

Compute the power functions of a matrix.

The operator `pow_matrix` computes the power of the input `Matrix` by a constant value. The input `Matrix` is given by the matrix handle `MatrixID`. The power value is given by the parameter `Power`. A new matrix
MatrixPow is generated with the result. The operator returns the matrix handle \( \text{MatrixPowID} \) of the matrix \( \text{MatrixPow} \). Access to the elements of the matrix is possible e.g. with the operator \( \text{get_full_matrix} \).

The type of the Matrix can be selected via \( \text{MatrixType} \). The following values are supported: ‘general’ for general, ‘symmetric’ for symmetric, ‘positive_definite’ for symmetric positive definite, ‘upper_triangular’ for upper triangular, ‘permuted_upper_triangular’ for permuted upper triangular, ‘lower_triangular’ for lower triangular, and ‘permuted_lower_triangular’ for permuted lower triangular matrices. The formula for the calculation of the result is:

\[
\text{MatrixPow} = \text{MatrixPower}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 2.0
\end{bmatrix}
\]

\[\text{Power} = \begin{bmatrix} 2.0 \end{bmatrix} \quad \text{MatrixType} = \text{’general’} \]

\[
\rightarrow \quad \begin{bmatrix}
32.0 & 18.0 & 10.0 \\
68.0 & 62.0 & 26.0 \\
56.0 & 41.0 & 27.0
\end{bmatrix}
\]

Attention

For \( \text{MatrixType} = \text{’symmetric’}, \text{’positive_definite’}, \text{’upper_triangular’} \) the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For \( \text{MatrixType} = \text{’lower_triangular’} \) the lower triangular part of the input Matrix must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

---

**Parameters**

- \( \text{MatrixID} \) (input_control) \( \quad \) \( \text{matrix} \) \( \Rightarrow \text{handle} \)
  - Matrix handle of the input matrix.

- \( \text{MatrixType} \) (input_control) \( \quad \) \( \text{string} \) \( \Rightarrow \text{string} \)
  - The type of the input matrix.
    - **Default value:** ‘general’
    - **List of values:** \( \text{MatrixType} \in \{ \text{’general’}, \text{’symmetric’}, \text{’positive_definite’}, \text{’upper_triangular’}, \text{’permuted_upper_triangular’}, \text{’lower_triangular’}, \text{’permuted_lower_triangular’} \} \)

- \( \text{Power} \) (input_control) \( \quad \) \( \text{number} \) \( \Rightarrow \text{real} / \text{integer} \)
  - The power.
    - **Default value:** 2.0
    - **Suggested values:** \( \text{Power} \in \{ 0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0 \} \)

- \( \text{MatrixPowID} \) (output_control) \( \quad \) \( \text{matrix} \) \( \Rightarrow \text{handle} \)
  - Matrix handle with the raised powered matrix.

---

**Result**

If the parameters are valid, the operator \( \text{pow_matrix} \) returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module Foundation

**pow_matrix_mod** (: : MatrixID, MatrixType, Power : )

Compute the power functions of a matrix.

The operator **pow_matrix_mod** computes the power of the input *Matrix* by a constant value. The input *Matrix* is given by the matrix handle *MatrixID*. The power value is given by the parameter *Power*. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

The type of the *Matrix* can be selected via *MatrixType*. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices. The formula for the calculation of the result is:

\[
\text{Matrix} = \text{Matrix}^{\text{Power}}.
\]

Example:

\[
\begin{pmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{pmatrix}
\]

\[
\begin{pmatrix}
2.0
\end{pmatrix}
\]

\[
\text{MatrixType} = \text{’general'}
\]

\[
\begin{pmatrix}
32.0 & 18.0 & 10.0 \\
68.0 & 62.0 & 26.0 \\
56.0 & 41.0 & 27.0
\end{pmatrix}
\]

**Attention**

For *MatrixType = ‘symmetric’, ‘positive_definite’, or ‘upper_triangular’* the upper triangular part of the input *Matrix* must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For *MatrixType = ‘lower_triangular’* the lower triangular part of the input *Matrix* must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. If the referenced part of the input *Matrix* is not of the specified type, an exception is raised.

**Parameters**

- **MatrixID** (input_control) : matrix handle
  Matrix handle of the input matrix.

- **MatrixType** (input_control) : string
  The type of the input matrix.
  Default value: 'general'
  List of values: MatrixType ∈ {'general', 'symmetric', 'positive_definite', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}

- **Power** (input_control) : number
  The power.
  Default value: 2.0
  Suggested values: Power ∈ {0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}

**Result**

If the parameters are valid, the operator **pow_matrix_mod** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**pow_scalar_element_matrix** ( : : MatrixID, Power : MatrixPowID )

*Compute the power functions of the elements of a matrix.*

The operator **pow_scalar_element_matrix** computes the power of all elements of the input Matrix by a constant value. The input Matrix is given by the matrix handle **MatrixID**. The power value is given by the parameter **Power**. A new matrix **MatrixPow** is generated with the result. The operator returns the matrix handle **MatrixPowID** of the matrix **MatrixPow**. Access to the elements of the matrix is possible e.g. with the operator **get_full_matrix**. The formula for the calculation of the result is:

\[ \text{MatrixPow}_{ij} = \text{Matrix}_{ij}^{\text{Power}}. \]

**Example:**

\[ \begin{bmatrix}
    3.0 & 1.0 & 2.0 \\
    5.0 & 7.0 & 2.0 \\
    9.0 & 4.0 & 1.0
\end{bmatrix} \quad \text{Power} = \begin{bmatrix} 2.0 \end{bmatrix} \]

\[ \Rightarrow \begin{bmatrix}
    9.0 & 1.0 & 4.0 \\
    25.0 & 49.0 & 4.0 \\
    81.0 & 16.0 & 1.0
\end{bmatrix} \]

### Parameters

- **MatrixID** (input_control) .......................... matrix  \(~\text{handle}\)  
  Matrix handle of the input matrix.
- **Power** (input_control) .......................... number  \(~\text{real/int}\)  
  The power.
  **Default value:** 2.0
  **Suggested values:** Power \(\in\{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}\)
- **MatrixPowID** (output_control) .......................... matrix  \(~\text{handle}\)  
  Matrix handle with the raised power of the input matrix.

### Result

If the parameters are valid, the operator **pow_scalar_element_matrix** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).

### `pow_scalar_element_matrix_mod ( : : MatrixID, Power : )`

**Compute the power functions of the elements of a matrix.**

The operator `pow_scalar_element_matrix_mod` computes the power of all elements of the input matrix by a constant value. The input matrix is given by the matrix handle `MatrixID`. The power value is given by the parameter `Power`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{Matrix}_{ij}^\text{Power}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
5.0 & 7.0 & 2.0 \\
9.0 & 4.0 & 1.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
9.0 & 1.0 & 4.0 \\
25.0 & 49.0 & 4.0 \\
81.0 & 16.0 & 1.0
\end{bmatrix}
\]

**Parameters**

- `MatrixID` (input_control) .......................... matrix \(\sim\) handle
  Matrix handle of the input matrix.

- `Power` (input_control) .......................... number \(\sim\) real / integer
  The power.

  **Default value:** 2.0
  **Suggested values:** `Power \in \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}

**Result**

If the parameters are valid, the operator `pow_scalar_element_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:
• MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

scale_matrix ( : : MatrixID, Factor : MatrixScaledID )

Scale a matrix.

The operator scale_matrix scales the Matrix by a constant factor. The matrix is defined by the matrix handle MatrixID. A new matrix MatrixScaled is generated with the result. The operator returns the matrix handle MatrixScaledID. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[
\text{MatrixScaled}_{ij} = \text{Factor} \times \text{Matrix}_{ij}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-2.0 & 6.0 & 2.0 \\
-5.0 & -4.0 & 1.0
\end{bmatrix}
\]

\[
\text{Factor} = 1.5
\]

\[
\begin{bmatrix}
4.5 & 1.5 & -3.0 \\
-3.0 & 9.0 & 3.0 \\
-7.5 & -6.0 & 1.5
\end{bmatrix}
\]

Parameters

▷ MatrixID (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . matrix \( \sim \) handle Matrix handle of the input matrix.

▷ Factor (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . number \( \sim \) real / integer Scale factor.

Default value: 2.0

Suggested values: Factor \( \in \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}\)

▷ MatrixScaledID (output_control) . . . . . . . . . . . . . . . . . . . . matrix \( \sim \) handle Matrix handle with the scaled elements.

Result

If the parameters are valid, the operator scale_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
19.2. ARITHMETIC

scale_matrix_mod ( : : MatrixID, Factor : )

Scale a matrix.

The operator scale_matrix scales the Matrix by a constant factor. The matrix is defined by the matrix handle MatrixID. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix. The formula for the calculation of the result is:

\[
Matrix_{ij} = Factor \cdot Matrix_{ij}.
\]

Example:

\[
Matrix = \begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-2.0 & 6.0 & 2.0 \\
-5.0 & -4.0 & 1.0
\end{bmatrix} \quad Factor = 1.5
\]

\[
\rightarrow Matrix = \begin{bmatrix}
4.5 & 1.5 & -3.0 \\
-3.0 & 9.0 & 3.0 \\
-7.5 & -6.0 & 1.5
\end{bmatrix}
\]

Parameters

- **MatrixID** (input_control) ................................. matrix \( \rightarrow \) handle
  Matrix handle of the input matrix.
- **Factor** (input_control) ................................. number \( \rightarrow \) real / integer
  Scale factor.
  **Default value:** 2.0
  **Suggested values:** Factor \( \in \{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0\}\)

Result

If the parameters are valid, the operator scale_matrix_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

solve_matrix ( : : MatrixLHSID, MatrixLHSType, Epsilon, MatrixRHSID : MatrixResultID )

Compute the solution of a system of equations.

The operator solve_matrix computes the solution of a system of linear equations or of a linear least squares problem. The input matrices MatrixLHS and MatrixRHS are defined by the matrix handles MatrixLHSID and MatrixRHSID. The number of rows of matrices MatrixLHS and MatrixRHS must be identical. The operator returns the matrix handle MatrixResultID of the matrix MatrixResult. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

For linear equation systems, the equations

\[
\text{MatrixLHS} \cdot \text{MatrixResult} = \text{MatrixRHS}
\]

are solved. Therefore, the matrix MatrixLHS must be a square matrix and the parameter Epsilon must be 0. The type of the matrix MatrixLHS can be selected via the parameter MatrixLHSType. The following values are supported: ‘general’ for general, ‘symmetric’ for symmetric, ‘positive_definite’ for symmetric positive definite, ‘tridiagonal’ for tridiagonal, ‘upper_triangular’ for upper triangular, ‘permuted_upper_triangular’ for permuted upper triangular, ‘lower_triangular’ for lower triangular, and ‘permuted_lower_triangular’ for permuted lower triangular matrices.

Example:

\[
\begin{bmatrix}
6.0 & 5.0 & 3.0 \\
5.0 & 7.0 & 3.0 \\
3.0 & 3.0 & 4.0
\end{bmatrix}
\begin{bmatrix}
\text{MatrixLHS} \\
\text{MatrixRHS}
\end{bmatrix}
\]

\[
\begin{bmatrix}
\text{MatrixLHSType} = \text{positive_definite} & \text{Epsilon = 0}
\end{bmatrix}
\]

\[
\begin{bmatrix}
-2.0 & 3.0 \\
1.0 & -3.0 \\
2.0 & 1.0
\end{bmatrix}
\]

For linear least squares problems or if Epsilon is not 0, the matrix MatrixLHS need not be a square matrix. The linear least squares problem is solved using the singular value decomposition (SVD) of the matrix MatrixLHS by minimizing

\[
\| \text{MatrixRHS} - \text{MatrixLHS} \cdot \text{MatrixResult} \|.
\]

All singular values less than the value Epsilon \times \text{the largest singular value} are set to 0. For these values no internal division is done to prevent a division by zero. Also, the matrix MatrixLHS may be rank-deficient. The type of matrix must be selected via MatrixLHSType = ‘general’.

Example:
**Matrix LHS** = \[
\begin{bmatrix}
6.0 & 5.0 & 3.0 \\
3.0 & 7.0 & -3.0 \\
5.0 & 12.0 & 4.0 \\
5.0 & 4.0 & 12.0 \\
4.0 & 6.0 & 8.0
\end{bmatrix}\]

**Matrix RHS** = \[
\begin{bmatrix}
29.0 \\
10.0 \\
35.0 \\
43.0 \\
25.0
\end{bmatrix}\]

**Matrix LHSType** = 'general'  
**Epsilon** = 2.2204e-16

\[\rightarrow\text{ MatrixResult} = \begin{bmatrix}
3.4914 \\
0.7114 \\
1.6213
\end{bmatrix}\]

Note: The relative accuracy of the floating point representation of the used data type (double) is **Epsilon** = 2.2204e-16.

**Attention**
For **Matrix LHSType** = 'symmetric', 'positive_definite', or 'upper_triangular' the upper triangular part of the input **Matrix LHS** must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For **Matrix LHSType** = 'lower_triangular' the lower triangular part of the input **Matrix LHS** must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For **Matrix LHSType** = 'tridiagonal', only the main diagonal, the superdiagonal, and the subdiagonal of the input **Matrix LHS** are used. The other parts of the matrix are not referenced. If the referenced part of the input **Matrix LHS** is not of the specified type, an exception is raised.

**Parameters**

- **MatrixLHSID** (input_control) matrix handle of the input matrix of the left hand side.
- **MatrixLHSType** (input_control) string The type of the input matrix of the left hand side.
  - Default value: 'general'
  - List of values: **Matrix LHSType** ∈ {'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- **Epsilon** (input_control) real Type of solving and limitation to set singular values to be 0.
  - Default value: 0.0
  - Suggested values: **Epsilon** ∈ {0.0, 2.2204e-16}
- **MatrixRHSID** (input_control) matrix handle of the input matrix of right hand side.
- **MatrixResultID** (output_control) matrix New matrix handle with the solution.

**Result**
If the parameters are valid, the operator **solve_matrix** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

sqrt_matrix ( : : MatrixID : MatrixSqrtID )
```

*Compute the square root values of the elements of a matrix.*

The operator `sqrt_matrix` computes the square root values of all elements of the input `Matrix` given by the matrix handle `MatrixID`. A new matrix `MatrixSqrt` is generated with the result. The operator returns the matrix handle `MatrixSqrtID` of the matrix `MatrixSqrt`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{MatrixSqrt}_{ij} = \sqrt{\text{Matrix}_{ij}}.
\]

**Example:**

```
Matrix = \[
3.0 \ 1.0 \ 2.0 \\
5.0 \ 7.0 \ 2.0 \\
9.0 \ 4.0 \ 1.0
\]  
\rightarrow \quad \text{MatrixSqrt} = \[
1.7321 \ 1.0000 \ 1.4142 \\
2.2361 \ 2.6458 \ 1.4142 \\
3.0000 \ 2.0000 \ 1.0000
\]
```

**Parameters**

If the parameters are valid, the operator `sqrt_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

---

**Possible Predecessors**

- `create_matrix`

**Possible Successors**

- `get_full_matrix`, `get_value_matrix`

**Alternatives**

- `sqrt_matrix`

---

**Sub_Module**

The operator `sub_matrix` computes the difference of the input matrices `MatrixA` and `MatrixB` given by the matrix handles `MatrixAID` and `MatrixBID`. Both matrices must have identical dimensions. A new matrix `MatrixSub` is generated with the result. The operator returns the matrix handle `MatrixSubID` of the matrix `MatrixSub`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The formula for the calculation of the result is:

\[
\text{MatrixSub} = \text{MatrixA} - \text{MatrixB}.
\]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\begin{bmatrix}
2.0 & 8.0 & -3.0 \\
-4.0 & -1.0 & 5.0 \\
2.0 & -4.0 & 7.0
\end{bmatrix}
\]
\[ \text{MatrixSub} = \begin{bmatrix} 1.0 & -7.0 & 1.0 \\ -1.0 & 8.0 & -3.0 \\ -11.0 & 0.0 & -6.0 \end{bmatrix} \]

Parameters

\>
\> \text{MatrixAID} (\text{input\_control}) \text{ matrix} \xrightarrow{\text{handle}} \text{Matrix handle of the input matrix A.}
\>
\> \text{MatrixBID} (\text{input\_control}) \text{ matrix} \xrightarrow{\text{handle}} \text{Matrix handle of the input matrix B.}
\>
\> \text{MatrixSubID} (\text{output\_control}) \text{ matrix} \xrightarrow{\text{handle}} \text{Matrix handle with the difference of the input matrices.}

Result

If the parameters are valid, the operator \text{sub\_matrix} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

\text{Foundation}

\text{sub\_matrix\_mod} \{ : : \text{MatrixAID}, \text{MatrixBID} : \}

\text{Subtract two matrices.}

The operator \text{sub\_matrix\_mod} computes the difference of the input matrices \text{MatrixA} and \text{MatrixB} given by the matrix handles \text{MatrixAID} and \text{MatrixBID}. Both matrices must have identical dimensions. The input matrix \text{MatrixA} is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator \text{get\_full\_matrix}. The formula for the calculation of the result is:

\[ \text{MatrixA} = \text{MatrixA} - \text{MatrixB}. \]

Example:

\[ \text{MatrixA} = \begin{bmatrix} -3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 2.0 & 8.0 & -3.0 \\ -4.0 & -1.0 & 5.0 \\ 2.0 & -4.0 & 7.0 \end{bmatrix} \]

\[ \rightarrow \text{MatrixA} = \begin{bmatrix} 1.0 & -7.0 & 1.0 \\ -1.0 & 8.0 & -3.0 \\ -11.0 & 0.0 & -6.0 \end{bmatrix} \]
19.2. ARITHMETIC

Parameters

MatrixAID (input_control) .................................................. matrix  ⇆ handle
Matrix handle of the input matrix A.

MatrixBID (input_control) .................................................. matrix  ⇆ handle
Matrix handle of the input matrix B.

Result

If the parameters are valid, the operator sub_matrix_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• MatrixAID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

transpose_matrix ( : : MatrixID : MatrixTransposedID )

Transpose a matrix.

The operator transpose_matrix returns the transpose of the input Matrix. The input matrix is defined by the matrix handle MatrixID. A new matrix MatrixTransposed is generated with the result and the matrix handle MatrixTransposedID of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

Example:

Matrix = \[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\] \rightarrow MatrixTransposed = \[
\begin{bmatrix}
3.0 & -5.0 & -9.0 \\
1.0 & 7.0 & -4.0 \\
-2.0 & 2.0 & 1.0
\end{bmatrix}
\]

Parameters

MatrixID (input_control) .................................................. matrix  ⇆ handle
Matrix handle of the input matrix.

MatrixTransposedID (output_control) .................................. matrix  ⇆ handle
Matrix handle with the transpose of the input matrix.

Result

If the parameters are valid, the operator transpose_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

Foundation

\textbf{\textit{transpose\_matrix\_mod}} \( (\text{\textbf{\textit{MatrixID}}}) \)

Transpose a matrix.

The operator \textit{transpose\_matrix\_mod} returns the transpose of the input \textit{Matrix}. The input matrix is defined by the matrix handle \textit{MatrixID}. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g. with the operator \textit{get\_full\_matrix}.

Example:

\[
\begin{pmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{pmatrix}
\rightarrow
\begin{pmatrix}
3.0 & -5.0 & -9.0 \\
1.0 & 7.0 & -4.0 \\
-2.0 & 2.0 & 1.0
\end{pmatrix}
\]

Parameters

\textbf{\textit{MatrixID}} (input_control) \hspace{1cm} \textit{matrix \sim handle}

Matrix handle of the input matrix.

Result

If the parameters are valid, the operator \textit{transpose\_matrix\_mod} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• \textit{MatrixID}

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
19.3 Creation

**clear_matrix** ( : : MatrixID : )

Free the memory of a matrix.

The operator clear_matrix frees the memory of the matrix Matrix given by the matrix handle MatrixID. After calling clear_matrix, the Matrix can no longer be used. The matrix handle MatrixID becomes invalid.

**Parameters**

> **MatrixID** (input_control) .......................... matrix(-array)  \sim handle
Matrix handle.

**Result**

If the parameters are valid, the operator clear_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**copy_matrix** ( : : MatrixID : MatrixCopyID )

Copy a matrix.

The operator copy_matrix creates the new matrix MatrixCopy and copies all elements of the input Matrix to this new matrix. The input Matrix is defined by the matrix handle MatrixID. The operator returns the matrix handle MatrixCopyID of the matrix MatrixCopy. Access to the elements of the matrix is possible e.g. with
the operator `get_full_matrix`. With this operator a matrix can be saved before the matrix is modified by the operators `set_value_matrix`, `set_full_matrix`, `set_sub_matrix`, or `set_diagonal_matrix`.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\rightarrow
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\]

---

**Parameters**

- `MatrixID` (input_control) .......................... matrix  \(\rightarrow\) handle
  Matrix handle of the input matrix.
- `MatrixCopyID` (output_control) ...................... matrix  \(\rightarrow\) handle
  Matrix handle of the copied matrix.

---

**Result**

If the parameters are valid, the operator `copy_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Possible Predecessors**

`create_matrix`

---

**Possible Successors**

`get_full_matrix`, `get_value_matrix`

---

**Alternatives**

`repeat_matrix`

---

**Module**

`Foundation`

---

**create_matrix** ( : : Rows, Columns, Value : MatrixID )

Create a matrix.

The operator `create_matrix` creates a new Matrix with `Rows` rows and `Columns` columns and returns the matrix handle `MatrixID`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The parameter `Value` is a string or a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically.

If `Value` = `'identity'`, `Rows` and `Columns` must have the identical values and an identity matrix is created.

Example:

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

If the parameter `Value` contains a single value, all elements of the matrix are filled with this value.

Example:

\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]
19.3. CREATION

→ Matrix =

\[
\begin{bmatrix}
7.0 & 7.0 & 7.0 \\
7.0 & 7.0 & 7.0 \\
7.0 & 7.0 & 7.0
\end{bmatrix}
\]

If \texttt{Value} contains as many values as the main diagonal, all elements of the main diagonal are set to the values of the parameter \texttt{Value} (i.e., the number of elements in \texttt{Value} is identical).

Example:

\begin{align*}
\text{Rows} & = 3 & \text{Columns} & = 4 & \text{Value} & = [3,7,1] \\
\Rightarrow \text{Matrix} & =
\begin{bmatrix}
3.0 & 0 & 0 & 0 \\
0 & 7.0 & 0 & 0 \\
0 & 0 & 1.0 & 0
\end{bmatrix}
\end{align*}

It is also possible to set all elements of the matrix with different values. In this case the parameter \texttt{Value} must contain all values in a row-major order, i.e., stored line by line. In addition, the number of elements of \texttt{Value} must be identical to the number of all elements of the matrix, i.e., \texttt{Rows} × \texttt{Columns}.

Example:

\begin{align*}
\text{Rows} & = 3 & \text{Columns} & = 3 & \text{Value} & = [3,1,-2,-5,7,2,-9,-4,1] \\
\Rightarrow \text{Matrix} & =
\begin{bmatrix}
3.0 & 1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\end{align*}

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.

### Parameters

- **\texttt{Rows}** (input_control) ........................................................................... integer ~ integer
  Number of rows of the matrix.
  **Default value:** 3
  **Suggested values:** \texttt{Rows} ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** \texttt{Rows} ≥= 1

- **\texttt{Columns}** (input_control) ..................................................................... integer ~ integer
  Number of columns of the matrix.
  **Default value:** 3
  **Suggested values:** \texttt{Columns} ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}
  **Restriction:** \texttt{Columns} ≥= 1

- **\texttt{Value}** (input_control) .............................................................................. number(-array) ~ real / integer / string
  Values for initializing the elements of the matrix.
  **Default value:** 0
  **Suggested values:** \texttt{Value} ∈ \{0, 1, 'identity'\}

- **\texttt{MatrixID}** (output_control) ................................................................. matrix ~ handle
  Matrix handle.

### Result

If the parameters are valid, the operator \texttt{create_matrix} returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_full_matrix, clear_matrix

Module

Foundation

repeat_matrix ( : : MatrixID, Rows, Columns : : MatrixRepeatedID )

Repeat a matrix.

The operator repeat_matrix creates the new matrix MatrixRepeated and copies all elements of the input Matrix n times to this new matrix, where \( n = \text{Rows} \times \text{Columns} \). The new matrix has dimensions \( \text{Rows} \times \text{rows of the input Matrix} \) and \( \text{Columns} \times \text{columns of the input Matrix} \). The input Matrix is defined by the matrix handle MatrixID. The operator returns the matrix handle MatrixRepeatedID of the matrix MatrixRepeated. Access to the elements of the matrix is possible e.g. with the operator get_full_matrix.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & -1.0 & -2.0 \\
-5.0 & 7.0 & 2.0
\end{bmatrix}
\]

\( \text{Rows} = 2 \quad \text{Columns} = 3 \)

\[
\text{MatrixRepeated} = \begin{bmatrix}
3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 \\
3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 \\
-5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0
\end{bmatrix}
\]

Parameters

▷ MatrixID (input_control) ................................................................. matrix \( \sim \) handle
Matrix handle of the input matrix.

▷ Rows (input_control) ................................................................. integer \( \sim \) integer
Number of copies of input matrix in row direction.
Default value: 2
Suggested values: Rows \( \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20\} \)
Restriction: Rows \( \geq 1 \)

▷ Columns (input_control) ................................................................. integer \( \sim \) integer
Number of copies of input matrix in column direction.
Default value: 2
Suggested values: Columns \( \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20\} \)
Restriction: Columns \( \geq 1 \)

▷ MatrixRepeatedID (output_control) .............................................. matrix \( \sim \) handle
Matrix handle of the repeated copied matrix.

Result

If the parameters are valid, the operator repeat_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.
19.4 Decomposition

**decompose_matrix** ( : : MatrixID, MatrixType : Matrix1ID, Matrix2ID )

Decompose a matrix.

The operator `decompose_matrix` decomposes the square input `Matrix` given by the matrix handle `MatrixID`. The results are stored in two generated matrices `Matrix1` and `Matrix2`. The operator returns the matrix handles `Matrix1ID` and `Matrix2ID`. Access to the elements of the matrices is possible e.g. with the operator `get_full_matrix`.

The type of the input `Matrix` can be selected via the parameter `MatrixType`. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, and 'tridiagonal' for tridiagonal matrices.

The decomposition `MatrixType` = 'general' or 'tridiagonal' is a LU factorization (Lower/Upper) with the form

\[ Matrix = Matrix1 \cdot Matrix2. \]

The output `Matrix1` is a lower triangular matrix with unit diagonal elements and interchanged rows. The output `Matrix2` is an upper triangular matrix.

Example for a factorization of a general matrix:

\[
\begin{pmatrix}
5.0 & -3.0 & 1.0 \\
0.0 & 2.0 & -1.0 \\
-5.0 & -1.0 & 5.0
\end{pmatrix}
\]

\[ \rightarrow \]

\[
\begin{pmatrix}
1 & 0 & 0 \\
0.0 & -0.5 & 1 \\
-1.0 & 1 & 0
\end{pmatrix} \quad \begin{pmatrix}
5.0 & -3.0 & 1.0 \\
0 & -4.0 & 6.0 \\
0 & 0 & 2.0
\end{pmatrix}
\]

Example for a factorization of a tridiagonal matrix:

\[
\begin{pmatrix}
-8.0 & 0.0 & 0.0 \\
-8.0 & 6.0 & -4.0 \\
0.0 & 7.0 & -2.0 \\
0.0 & 0.0 & 5.0
\end{pmatrix}
\]

\[ \rightarrow \]

\[
\begin{pmatrix}
1 & 0 & 0 & 0 \\
1.0 & 1 & 0 & 0 \\
0.0 & 0.5 & 0 & 1 \\
0.0 & 0.0 & 1 & 0
\end{pmatrix} \quad \begin{pmatrix}
-8.0 & -8.0 & 0.0 & 0.0 \\
0 & 14.0 & -4.0 & 0.0 \\
0 & 0 & 5.0 & -3.0 \\
0 & 0 & 0 & 7.0
\end{pmatrix}
\]

Example for a factorization of a symmetric matrix:

\[
\begin{pmatrix}
-8.0 & -8.0 & 0.0 & 0.0 \\
-8.0 & 6.0 & -4.0 & 0.0 \\
0.0 & 7.0 & -2.0 & 7.0 \\
0.0 & 0.0 & 5.0 & -3.0
\end{pmatrix}
\]

\[ \rightarrow \]

\[
\begin{pmatrix}
1 & 0 & 0 & 0 \\
1.0 & 1 & 0 & 0 \\
0.0 & 0.5 & 0 & 1 \\
0.0 & 0.0 & 1 & 0
\end{pmatrix} \quad \begin{pmatrix}
-8.0 & -8.0 & 0.0 & 0.0 \\
0 & 14.0 & -4.0 & 0.0 \\
0 & 0 & 5.0 & -3.0 \\
0 & 0 & 0 & 7.0
\end{pmatrix}
\]

For `MatrixType` = 'symmetric' the factorization is a UDU^T decomposition (Upper/Diagonal/Upper) with the form

\[ Matrix = Matrix1 \cdot Matrix2 \cdot Matrix1^T \]
where the output Matrix1 is an upper triangular matrix with interchanged columns. The output matrix Matrix2 is a symmetric block diagonal matrix with 1 × 1 and 2 × 2 diagonal blocks.

Example for a factorization of a symmetric matrix:

\[
\begin{pmatrix}
3.0 & -2.0 & 7.0 & -1.0 \\
-2.0 & -2.0 & 4.0 & 0.0 \\
7.0 & 4.0 & 8.0 & 1.0 \\
-1.0 & 0.0 & 1.0 & 0.0 \\
\end{pmatrix}
\rightarrow
\begin{pmatrix}
0 & 0 & 1 & 0.0 \\
0 & 1 & 0.0 & 2.0 \\
1 & -1.0 & -1.0 & -10.0 \\
0 & 0 & 0 & 1.0 \\
\end{pmatrix}
\begin{pmatrix}
27.0 & 0 & 0 & 0 \\
0 & -2.0 & 0 & 0 \\
0 & 0 & 3.0 & -1.0 \\
0 & 0 & -1.0 & 0.0 \\
\end{pmatrix}
\]

For MatrixType = 'positive_definite' a Cholesky factorization is computed with the form

\[
\text{Matrix} = \text{Matrix1} \cdot \text{Matrix2}.
\]

where the output Matrix1 is a lower triangular matrix and the output matrix Matrix2 is an upper triangular matrix. Furthermore, the Matrix2 is the transpose of the matrix Matrix1.

Example for a factorization of a positive definite matrix:

\[
\begin{pmatrix}
9.0 & 12.0 & -6.0 \\
12.0 & 17.0 & -7.0 \\
-6.0 & -7.0 & 14.0 \\
\end{pmatrix}
\rightarrow
\begin{pmatrix}
3.0 & 0 & 0 \\
4.0 & 1.0 & 0 \\
-2.0 & 1.0 & 3.0 \\
\end{pmatrix}
\begin{pmatrix}
3.0 & 4.0 & -2.0 \\
0 & 1.0 & 1.0 \\
0 & 0 & 3.0 \\
\end{pmatrix}
\]

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.

Attention

For MatrixType = 'symmetric' or 'positive_definite', the upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For MatrixType = 'tridiagonal', only the main diagonal, the superdiagonal, and the subdiagonal of the input Matrix are used. The other parts of the matrix are not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

Parameters

- **MatrixID** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix  \( \rightarrow \) handle
  - Matrix handle of the input matrix.
- **MatrixType** (input_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . string  \( \rightarrow \) string
  - Type of the input matrix.
  - Default value: 'general'
  - List of values: MatrixType \( \in \{ 'general', 'symmetric', 'positive_definite', 'tridiagonal' \} \)
- **Matrix1ID** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix  \( \rightarrow \) handle
  - Matrix handle with the output matrix 1.
- **Matrix2ID** (output_control) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . matrix  \( \rightarrow \) handle
  - Matrix handle with the output matrix 2.

Result

If the parameters are valid, the operator decompose_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

References

Module

orthogonal_decompose_matrix ( : : MatrixID, DecompositionType, OutputMatricesType, ComputeOrthogonal : MatrixOrthogonalID, MatrixTriangularID )

Perform an orthogonal decomposition of a matrix.

The operator orthogonal_decompose_matrix decomposes the Matrix defined by the matrix handle MatrixID. The results are stored in the two generated matrices MatrixOrthogonal and MatrixTriangular. The operator returns the matrix handles MatrixOrthogonalID and MatrixTriangularID of these two matrices. Access to the elements of the matrices is possible e.g. with the operator get_full_matrix.

For OutputMatricesType = 'full' all results of the decomposition are stored in the matrices MatrixOrthogonal and MatrixTriangular. For OutputMatricesType = 'reduced' only a part of the result elements of the matrices MatrixOrthogonal and MatrixTriangular are stored. Therefore the sizes of these matrices are smaller than for OutputMatricesType = 'full'.

For the parameter ComputeOrthogonal = 'true' both output matrices are computed. For the ComputeOrthogonal = 'false' only the matrix MatrixTriangular is computed. Thus, the runtime of the operation takes fewer time.

The type of the Matrix can be selected via the parameter DecompositionType. For DecompositionType = 'qr' a QR decomposition (Quadratic/Right) or for DecompositionType = 'ql' a QL decomposition (Quadratic/Left) is computed. The decomposition is written as

\[
\text{Matrix} = \text{MatrixOrthogonal} \cdot \text{MatrixTriangular}.
\]

Example for DecompositionType = 'qr' and OutputMatricesType = 'full':

\[
\text{Matrix} = \begin{bmatrix} 6.0 & -3.0 & 4.0 \\ 5.0 & 5.0 & -2.0 \\ -3.0 & 12.0 & 5.0 \\ 3.0 & 4.0 & 7.0 \\ 7.0 & 5.0 & 3.0 \end{bmatrix}
\]

\[
\rightarrow \text{MatrixOrthogonal} = \begin{bmatrix} -0.5303 & 0.2613 & -0.4277 & -0.5566 & -0.3972 \\ -0.4419 & -0.2920 & -0.6383 & 0.1727 & -0.5312 \\ 0.2652 & -0.8443 & -0.2059 & -0.3961 & -0.1326 \\ -0.2652 & -0.2432 & -0.6008 & 0.7000 & -0.1400 \\ -0.6187 & -0.2729 & 0.0799 & -0.1160 & 0.7231 \end{bmatrix}
\]
Example for `DecompositionType = 'qr'` and `OutputMatricesType = 'reduced'`:

\[
\text{MatrixTriangular} = \begin{bmatrix}
-11.3137 & -1.5910 & -3.6239 \\
0 & -14.7129 & -5.1135 \\
0 & 0 & -7.9824 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\]

\[
\text{Matrix} = \begin{bmatrix}
6.0 & -3.0 & 4.0 \\
5.0 & 5.0 & -2.0 \\
-3.0 & 12.0 & 5.0 \\
3.0 & 4.0 & 7.0 \\
7.0 & 5.0 & 3.0
\end{bmatrix}
\]

\[
\rightarrow \quad \text{MatrixOrthogonal} = \begin{bmatrix}
-0.5303 & 0.2613 & -0.4277 \\
-0.4419 & -0.2920 & -0.6383 \\
-0.2652 & -0.2432 & -0.6008 \\
-0.6187 & -0.2729 & 0.0799
\end{bmatrix}
\]

\[
\text{MatrixTriangular} = \begin{bmatrix}
-11.3137 & -1.5910 & -3.6239 \\
0 & -14.7129 & -5.1135 \\
0 & 0 & -7.9824
\end{bmatrix}
\]

Example for `DecompositionType = 'ql'` and `OutputMatricesType = 'full'`:

\[
\text{Matrix} = \begin{bmatrix}
6.0 & -3.0 & 4.0 \\
5.0 & 5.0 & -2.0 \\
-3.0 & 12.0 & 5.0 \\
3.0 & 4.0 & 7.0 \\
7.0 & 5.0 & 3.0
\end{bmatrix}
\]

\[
\rightarrow \quad \text{MatrixOrthogonal} = \begin{bmatrix}
0.6806 & 0.0657 & 0.3659 & -0.4932 & -0.3941 \\
0.1161 & 0.5464 & 0.6091 & 0.5274 & 0.1971 \\
0.4093 & -0.0832 & -0.4046 & 0.6474 & -0.4927 \\
-0.5362 & 0.4713 & 0.0072 & -0.1298 & -0.6897 \\
-0.2611 & -0.6842 & 0.5757 & 0.2119 & -0.2956
\end{bmatrix}
\]

\[
\text{MatrixTriangular} = \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
10.5059 & 0 & 0 \\
-1.1429 & 12.4620 & 0 \\
-4.0399 & -7.9812 & -10.1489
\end{bmatrix}
\]

Example for `DecompositionType = 'ql'` and `OutputMatricesType = 'reduced'`:

\[
\text{Matrix} = \begin{bmatrix}
6.0 & -3.0 & 4.0 \\
5.0 & 5.0 & -2.0 \\
-3.0 & 12.0 & 5.0 \\
3.0 & 4.0 & 7.0 \\
7.0 & 5.0 & 3.0
\end{bmatrix}
\]

\[
\rightarrow \quad \text{MatrixOrthogonal} = \begin{bmatrix}
0.3659 & -0.4932 & -0.3941 \\
0.6091 & 0.5274 & 0.1971 \\
-0.4046 & 0.6474 & -0.4927 \\
0.0072 & -0.1298 & -0.6897 \\
0.5757 & 0.2119 & -0.2956
\end{bmatrix}
\]

\[
\text{MatrixTriangular} = \begin{bmatrix}
10.5059 & 0 & 0 \\
-1.1429 & 12.4620 & 0 \\
-4.0399 & -7.9812 & -10.1489
\end{bmatrix}
\]
For \texttt{DecompositionType} = 'rq' a RQ decomposition (Right/Quadratic) or for \texttt{DecompositionType} = 'lq' a LQ decomposition (Left/Quadratic) is computed. The decomposition is written as

\[
\text{Matrix} = \text{MatrixTriangular} \cdot \text{MatrixOrthogonal}.
\]

Example for \texttt{DecompositionType} = 'rq' and \texttt{OutputMatricesType} = 'full':

\[
\begin{align*}
\text{Matrix} &= \begin{bmatrix}
6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\
-3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\
4.0 & -2.0 & 5.0 & 7.0 & 3.0
\end{bmatrix} \\
\rightarrow \quad \text{MatrixOrthogonal} &= \begin{bmatrix}
0.6806 & 0.1161 & 0.4093 & -0.5362 & -0.2611 \\
0.0657 & 0.5464 & -0.0832 & 0.4713 & -0.6842 \\
-0.4932 & 0.5274 & 0.6474 & -0.1208 & 0.2119 \\
-0.3941 & 0.1971 & -0.4927 & -0.6897 & -0.2956
\end{bmatrix} \\
\text{MatrixTriangular} &= \begin{bmatrix}
0 & 0 & 10.5059 & -1.1429 & -4.0399 \\
0 & 0 & 0 & 12.4620 & -7.9812 \\
0 & 0 & 0 & 0 & -10.1489
\end{bmatrix}
\end{align*}
\]

Example for \texttt{DecompositionType} = 'rq' and \texttt{OutputMatricesType} = 'reduced':

\[
\begin{align*}
\text{Matrix} &= \begin{bmatrix}
6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\
-3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\
4.0 & -2.0 & 5.0 & 7.0 & 3.0
\end{bmatrix} \\
\rightarrow \quad \text{MatrixOrthogonal} &= \begin{bmatrix}
0.3659 & 0.6091 & -0.4046 & 0.0072 & 0.5757 \\
-0.4932 & 0.5274 & 0.6474 & -0.1208 & 0.2119 \\
-0.3941 & 0.1971 & -0.4927 & -0.6897 & -0.2956
\end{bmatrix} \\
\text{MatrixTriangular} &= \begin{bmatrix}
10.5059 & -1.1429 & -4.0399 \\
0 & 12.4620 & -7.9812 \\
0 & 0 & -10.1489
\end{bmatrix}
\end{align*}
\]

Example for \texttt{DecompositionType} = 'lq' and \texttt{OutputMatricesType} = 'full':

\[
\begin{align*}
\text{Matrix} &= \begin{bmatrix}
6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\
-3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\
4.0 & -2.0 & 5.0 & 7.0 & 3.0
\end{bmatrix} \\
\rightarrow \quad \text{MatrixOrthogonal} &= \begin{bmatrix}
-0.5303 & -0.4419 & 0.2652 & -0.2652 & -0.6187 \\
0.2613 & -0.2920 & -0.8443 & -0.2432 & -0.2729 \\
-0.4277 & 0.6383 & -0.2059 & -0.6008 & 0.0799 \\
-0.5566 & 0.1727 & -0.3961 & 0.7000 & -0.1160 \\
-0.3972 & -0.5312 & -0.1326 & -0.1400 & 0.7231
\end{bmatrix} \\
\text{MatrixTriangular} &= \begin{bmatrix}
-11.3137 & 0 & 0 & 0 & 0 \\
-1.5910 & -14.7129 & 0 & 0 & 0 \\
-3.6239 & -5.1135 & -7.9824 & 0 & 0
\end{bmatrix}
\end{align*}
\]

Example for \texttt{DecompositionType} = 'lq' and \texttt{OutputMatricesType} = 'reduced':

\[
\begin{align*}
\text{Matrix} &= \begin{bmatrix}
6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\
-3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\
4.0 & -2.0 & 5.0 & 7.0 & 3.0
\end{bmatrix} \\
\rightarrow \quad \text{MatrixOrthogonal} &= \begin{bmatrix}
-0.5303 & -0.4419 & 0.2652 & -0.2652 & -0.6187 \\
0.2613 & -0.2920 & -0.8443 & -0.2432 & -0.2729 \\
-0.4277 & 0.6383 & -0.2059 & -0.6008 & 0.0799
\end{bmatrix}
\end{align*}
\]
MatrixTriangular = \[
\begin{bmatrix}
-11.3137 & 0 & 0 \\
-1.5910 & -14.7129 & 0 \\
-3.6239 & -5.1135 & -7.9824
\end{bmatrix}
\]

It should be noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

### Parameters

- **MatrixID** (input_control) 
  Matrix handle of the input matrix.
- **DecompositionType** (input_control) 
  Method of decomposition.
  - Default value: 'qr'
  - List of values: DecompositionType ∈ {'qr', 'rq', 'ql', 'lq'}
- **OutputMatricesType** (input_control) 
  Type of output matrices.
  - Default value: 'full'
  - List of values: OutputMatricesType ∈ {'full', 'reduced'}
- **ComputeOrthogonal** (input_control) 
  Computation of the orthogonal matrix.
  - Default value: 'true'
  - List of values: ComputeOrthogonal ∈ {'true', 'false'}
- **MatrixOrthogonalID** (output_control) 
  Matrix handle with the orthogonal part of the decomposed input matrix.
- **MatrixTriangularID** (output_control) 
  Matrix handle with the triangular part of the decomposed input matrix.

### Result

If the parameters are valid, the operator *orthogonal_decompose_matrix* returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- `create_matrix`

### Possible Successors

- `get_full_matrix`, `get_value_matrix`
- `decompose_matrix`, `solve_matrix`

### References

### Module

- `svd_matrix` ( : : MatrixID, SVDType, 
  ComputeSingularVectors : MatrixUID, MatrixSID, MatrixVID )

*Compute the singular value decomposition of a matrix.*
The operator `svd_matrix` computes a full or reduced singular value decomposition (SVD) of the Matrix defined by the matrix handle `MatrixID`. The operator returns the matrix handle `MatrixSID` of the matrix `MatrixS` with singular values in descending order. Optionally, the matrices `MatrixU` with the left and `MatrixV` with the right singular vectors are computed and the matrix handles `MatrixUID` and `MatrixVID` are returned. Access to the elements of the matrices is possible e.g. with the operator `get_full_matrix`. The SVD is written

\[ \text{Matrix} = \text{MatrixU} \cdot \text{MatrixS} \cdot \text{MatrixV}^T. \]

For `SVDType = 'full'`, a full SVD is computed.

Example:

\[
\begin{pmatrix}
6.0 & -5.0 \\
10.0 & 4.0 \\
-3.0 & 5.0
\end{pmatrix}
\]

\[ SVDType = 'full' \quad \text{ComputeSingularVectors} = 'both' \]

\[
\begin{pmatrix}
-0.5228 & 0.5691 & 0.6346 \\
-0.8070 & -0.5702 & -0.1535 \\
0.2745 & -0.5924 & 0.7574
\end{pmatrix}
\]

\[
\begin{pmatrix}
12.0547 & 0 \\
0 & 8.1046 \\
0 & 0
\end{pmatrix}
\]

\[
\begin{pmatrix}
-0.9980 & -0.0629 \\
0.0629 & -0.9980
\end{pmatrix}
\]

For `SVDType = 'reduced'`, a reduced SVD is computed.

Example:

\[
\begin{pmatrix}
6.0 & -5.0 \\
10.0 & 4.0 \\
-3.0 & 5.0
\end{pmatrix}
\]

\[ SVDType = 'reduced' \quad \text{ComputeSingularVectors} = 'both' \]

\[
\begin{pmatrix}
-0.5228 & 0.5691 \\
-0.8070 & -0.5702 \\
0.2745 & -0.5924
\end{pmatrix}
\]

\[
\begin{pmatrix}
12.0547 & 0 \\
0 & 8.1046
\end{pmatrix}
\]

\[
\begin{pmatrix}
-0.9980 & -0.0629 \\
0.0629 & -0.9980
\end{pmatrix}
\]

For `ComputeSingularVectors = 'left'`, the matrix `MatrixU` with the left singular vectors is computed. For `ComputeSingularVectors = 'right'`, the matrix `MatrixV` with the right singular vectors is computed. For `ComputeSingularVectors = 'both'`, the matrices `MatrixU` and `MatrixV` with the left and right singular vectors are computed.

For `ComputeSingularVectors = 'none'`, no matrices with the singular vectors are computed. The matrix `MatrixS` is a matrix with \(n\) rows and one column, where the number \(n = \min(\text{number of rows of the input Matrix, number of columns of the input Matrix})\).

Example:

\[
\begin{pmatrix}
6.0 & -5.0 \\
10.0 & 4.0 \\
-3.0 & 5.0
\end{pmatrix}
\]

\[ SVDType = 'reduced' \text{ or } 'full' \quad \text{ComputeSingularVectors} = 'none' \]

\[
\begin{pmatrix}
12.0547 \\
8.1046
\end{pmatrix}
\]

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.
Parameters

- **MatrixID** (input_control) ............................. matrix  ~ handle
  Matrix handle of the input matrix.

- **SVDType** (input_control) ............................. string  ~ string
  Type of computation.
  Default value: ‘full’
  List of values: SVDType ∈ {‘full’, ‘reduced’}

- **ComputeSingularVectors** (input_control) ............ string  ~ string
  Computation of singular values.
  Default value: ‘both’
  List of values: ComputeSingularVectors ∈ {‘none’, ‘left’, ‘right’, ‘both’}

- **MatrixUID** (output_control) ........................... matrix  ~ handle
  Matrix handle with the left singular vectors.

- **MatrixSID** (output_control) ........................... matrix  ~ handle
  Matrix handle with singular values.

- **MatrixVID** (output_control) ........................... matrix  ~ handle
  Matrix handle with the right singular vectors.

Result

If the parameters are valid, the operator `svd_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

19.5 Eigenvalues

```c
eigenvalues_general_matrix ( : : MatrixID,
    ComputeEigenvectors : EigenvaluesRealID, EigenvaluesImagID,
    EigenvectorsRealID, EigenvectorsImagID )
```

Compute the eigenvalues and optionally the eigenvectors of a general matrix.

The operator `eigenvalues_general_matrix` computes all eigenvalues and, optionally, the left or right eigenvectors of a square, general `Matrix`. The matrix is defined by the matrix handle `MatrixID`. The computed eigenvectors have the norm 1.

The operator generates the new matrices `EigenvaluesReal` and `EigenvaluesImag` with the real and the imaginary parts of the computed eigenvalues. Each matrix has one column and \(n\) rows, where \(n\) is the number of rows of the input `Matrix`. In contrast to the operator `eigenvalues_symmetric_matrix`, the order of the eigenvalues is not defined. The operator returns the matrix handles `EigenvaluesRealID` and `EigenvaluesImagID`. If desired, the real and imaginary parts of the computed eigenvectors are stored in the
new matrices $\text{EigenvectorsReal}$ and $\text{EigenvectorsImag}$. For this, the operator returns valid matrix handles $\text{EigenvectorsRealID}$ and $\text{EigenvectorsImagID}$. Access to the elements of the matrix is possible e.g. with the operator $\text{get\_full\_matrix}$. The computation type of eigenvectors can be selected via the parameter $\text{ComputeEigenvectors}$. If $\text{ComputeEigenvectors} = 'none'$, no eigenvectors are computed. If 'left' is selected, the left eigenvalues are computed. If 'right' is selected, the right eigenvalues are computed.

Example:

$$\text{Matrix} = \begin{bmatrix} 6.0 & 4.0 & -8.0 \\ 5.0 & 7.0 & 3.0 \\ 4.0 & -1.0 & 4.0 \end{bmatrix} \quad \text{ComputeEigenvectors} = 'right'$$

$$\Rightarrow \text{EigenvaluesReal} = \begin{bmatrix} 3.3110 \\ 3.3110 \\ 10.3781 \end{bmatrix} \quad \text{EigenvaluesImag} = \begin{bmatrix} 5.4143 \\ 5.4143 \\ 0.0 \end{bmatrix}$$

$$\text{EigenvectorsReal} = \begin{bmatrix} 0.6353 & 0.6353 & 0.4813 \\ -0.4764 & -0.4764 & 0.8605 \\ -0.0246 & -0.0246 & 0.1669 \end{bmatrix}$$

$$\text{EigenvectorsImag} = \begin{bmatrix} 0.0 & 0.0 & 0.0 \\ -0.2485 & 0.2485 & 0.0 \\ -0.5542 & 0.5542 & 0.0 \end{bmatrix}$$

Parameters

- **MatrixID** (input_control) ......................................................... matrix $\rightsquigarrow$ handle
  Matrix handle of the input matrix.

- **ComputeEigenvectors** (input_control) ........................................ string $\rightsquigarrow$ string
  Computation of the eigenvectors.

  Default value: 'none'

  List of values: ComputeEigenvectors $\in \{ 'none', 'left', 'right' \}$

- **EigenvaluesRealID** (output_control) ........................................... matrix $\rightsquigarrow$ handle
  Matrix handle with the real parts of the eigenvalues.

- **EigenvaluesImagID** (output_control) ........................................... matrix $\rightsquigarrow$ handle
  Matrix handle with the imaginary parts of the eigenvalues.

- **EigenvectorsRealID** (output_control) ........................................... matrix $\rightsquigarrow$ handle
  Matrix handle with the real parts of the eigenvectors.

- **EigenvectorsImagID** (output_control) ........................................... matrix $\rightsquigarrow$ handle
  Matrix handle with the imaginary parts of the eigenvectors.

Result

If the parameters are valid, the operator $\text{eigenvalues\_general\_matrix}$ returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

HALCON 20.11.0.0
References

Module
eigenvalues_symmetric_matrix ( : : MatrixID, ComputeEigenvectors : EigenvaluesID, EigenvectorsID )

Compute the eigenvalues and optionally eigenvectors of a symmetric matrix.

The operator eigenvalues_symmetric_matrix computes all eigenvalues and, optionally, eigenvectors of the symmetric Matrix. The matrix is defined by the matrix handle MatrixID. On output, a new matrix Eigenvalues with the eigenvalues in ascending order and, optionally, a new matrix Eigenvectors with the eigenvectors is created. The operator returns the matrix handles EigenvaluesID and EigenvectorsID of the matrices Eigenvalues and Eigenvectors. Access to the elements of the matrices is possible e.g. with the operator get_full_matrix.

The computation of eigenvectors can be selected via ComputeEigenvectors = 'true' or ComputeEigenvectors = 'false'.

Example:

Matrix = [ 6.0 5.0 3.0  
 5.0 7.0 3.0  
 3.0 3.0 4.0 ]

ComputeEigenvectors = 'true'

→Eigenvalues = [ 1.4195  
 2.1507  
 13.4298 ]

Eigenvectors = [ 0.7842 0.0626 0.6174  
 −0.5667 0.4776 0.6714  
 −0.2529 −0.8763 0.4100 ]

Attention
The upper triangular part of the input Matrix must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. If the referenced part of the input Matrix is not of the specified type, an exception is raised.

Parameters

▷ MatrixID (input_control) .................................................. matrix ∼ handle
Matrix handle of the input matrix.

▷ ComputeEigenvectors (input_control) ................................ string ∼ string
Computation of the eigenvectors.

Default value: 'false'
List of values: ComputeEigenvectors ∈ {'true', 'false'}

▷ EigenvaluesID (output_control) ........................................ matrix ∼ handle
Matrix handle with the eigenvalues.

▷ EigenvectorsID (output_control) ...................................... matrix ∼ handle
Matrix handle with the eigenvectors.

Result

If the parameters are valid, the operator eigenvalues_symmetric_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

generalized_eigenvalues_general_matrix ( : : MatrixAID, MatrixBID, ComputeEigenvectors : EigenvaluesRealID, EigenvaluesImagID, EigenvectorsRealID, EigenvectorsImagID )

Compute the generalized eigenvalues and optionally the generalized eigenvectors of general matrices.

The operator generalized_eigenvalues_general_matrix computes all generalized eigenvalues and, optionally, the left or right generalized eigenvectors of the square, general matrices MatrixA and MatrixB. Both matrices must have identical dimensions. The matrices are defined by the matrix handles MatrixAID and MatrixBID. The computed eigenvectors have the norm 1.

The operator generates the new matrices EigenvaluesReal and EigenvaluesImag with the real and the imaginary parts of the computed eigenvalues. Each matrix has one column and \( n \) rows, where \( n \) is the number of rows or columns of the input matrices. In contrast to the operator generalized_eigenvalues_symmetric_matrix, the order of the generalized eigenvalues is not defined. The operator returns the matrix handles EigenvaluesRealID and EigenvaluesImagID. If desired, the real and imaginary parts of the respective eigenvectors are stored in the new matrices EigenvectorsReal and EigenvectorsImag. Here, the \( j \)th column of the matrices of eigenvectors contains the related eigenvector to the \( j \)th eigenvalue. For this, the operator returns additionally the matrix handles EigenvectorsRealID and EigenvectorsImagID. Access to the elements of the matrix is possible, e.g., with the operator get_full_matrix or get_sub_matrix.

The computation type of eigenvectors can be selected via the parameter ComputeEigenvectors. If ComputeEigenvectors = 'none', no eigenvectors are computed and the operator is faster. For this, the matrix handles EigenvectorsRealID and EigenvectorsImagID are invalid. If 'right' is selected, the right generalized eigenvalues are computed. The formula for the calculation of the result is

\[
\text{MatrixA} \cdot x_j = \lambda_j \cdot \text{MatrixB} \cdot x_j,
\]

with \( \lambda_j \) representing the \( j \)th (complex) eigenvalue and \( x_j \) represents the corresponding (complex) eigenvector.

If 'left' is selected, the left generalized eigenvalues are computed. The formula for the calculation of the result is

\[
x_j^H \cdot \text{MatrixA} \cdot x_j^H = \lambda_j \cdot x_j^H \cdot \text{MatrixB},
\]

with \( x_j^H \) represents the conjugate-transposed of \( x_j \).

Example:

\[
\begin{bmatrix}
6.0 & 4.0 & -8.0 \\
5.0 & 7.0 & 3.0 \\

19.5. EIGENVALUES

\texttt{generalized\_eigenvalues\_symmetric\_matrix} ( : : \text{MatrixAID}, \text{MatrixBID, ComputeEigenvectors : EigenvaluesID, EigenvectorsID} )

**Compute the generalized eigenvalues and optionally generalized eigenvectors of symmetric input matrices.**

The operator \texttt{generalized\_eigenvalues\_symmetric\_matrix} computes all generalized eigenvalues and, optionally, generalized eigenvectors of the symmetric matrix \text{MatrixA} and the symmetric positive definite matrix \text{MatrixB}. Both matrices must have identical dimensions. The matrices are defined by the matrix handles \text{MatrixAID} and \text{MatrixBID}. On output, a new matrix \text{Eigenvalues} with the generalized eigenvalues in ascending order and, optionally, a new matrix \text{Eigenvectors} with the generalized eigenvectors is created. Each \(j\)th column of the matrix \text{Eigenvectors} contains the related eigenvector to the \(j\)th eigenvalue. The operator returns the matrix handles \text{EigenvaluesID} and \text{EigenvectorsID} of the matrices \text{Eigenvalues} and \text{Eigenvectors}. Access to the elements of the matrices is possible, e.g., with the operator \text{get\_full\_matrix} or \text{get\_sub\_matrix}.

The computation of generalized eigenvectors can be selected via \text{ComputeEigenvectors} = 'true'. The formula for the calculation of the result is

\[
\text{MatrixA} \cdot x_j = \lambda_j \cdot \text{MatrixB} \cdot x_j,
\]

with \(\lambda_j\) representing the \(j\)th eigenvalue and \(x_j\) represents the corresponding eigenvector.

If \text{ComputeEigenvectors} = 'false', no generalized eigenvectors are computed. For this, the matrix handle \text{EigenvectorsID} is invalid.

**Example:**

\[
\begin{bmatrix}
4.0 & -3.0 & 2.0 \\
-3.0 & 1.0 & 4.0 \\
2.0 & 4.0 & 8.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
6.0 & 5.0 & 3.0 \\
5.0 & 7.0 & 3.0 \\
3.0 & 4.0 & 3.0
\end{bmatrix}
\]

\text{ComputeEigenvectors} = 'true' \Rightarrow \text{Eigenvalues} = \begin{bmatrix} -0.4463 & 1.8747 & 4.5472 \end{bmatrix}

\text{Eigenvectors} = \begin{bmatrix}
-0.1579 & 0.1851 & -0.6358 \\
-0.3377 & -0.2568 & 0.4311 \\
0.2382 & 0.5065 & 0.3185
\end{bmatrix}

**Attention**

The upper triangular parts of the input matrices \text{MatrixA} and \text{MatrixB} must contain the relevant information of the matrices. The strictly lower triangular parts of the matrices are not referenced. If the referenced parts of the input matrices \text{MatrixA} or \text{MatrixB} are not of the specified type, an exception is raised.

**Parameters**

\begin{itemize}
\item \text{MatrixAID} (input_control) \hspace{1cm} \text{Matrix handle of the symmetric input matrix A.}
\item \text{MatrixBID} (input_control) \hspace{1cm} \text{Matrix handle of the symmetric positive definite input matrix B.}
\item \text{ComputeEigenvectors} (input_control) \hspace{1cm} \text{Computation of the eigenvectors.}
\end{itemize}

**Default value:** 'false'

**List of values:** \text{ComputeEigenvectors} \in \{ 'true', 'false' \}

**EigenvaluesID** (output_control) \hspace{1cm} \text{Matrix handle with the eigenvalues.}

**EigenvectorsID** (output_control) \hspace{1cm} \text{Matrix handle with the eigenvectors.}

**Result**

If the parameters are valid, the operator \text{generalized\_eigenvalues\_symmetric\_matrix} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

HALCON 20.11.0.0
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

### 19.6 Features

#### `determinant_matrix` ( : : MatrixID, MatrixType : Value )

Compute the determinant of a matrix.

The operator `determinant_matrix` computes the determinant of the input `Matrix` given by the matrix handle `MatrixID`. The type of the input `Matrix` can be selected via the parameter `MatrixType`. The following values are supported: ‘general’ for general, ‘symmetric’ for symmetric, ‘positive_definite’ for symmetric positive definite, ‘tridiagonal’ for tridiagonal, ‘upper_triangular’ for upper triangular, ‘permuted_upper_triangular’ for permuted upper triangular, ‘lower_triangular’ for lower triangular, and ‘permuted_lower_triangular’ for permuted lower triangular matrices. The formula for the calculation of the result is:

\[ \text{Value} = \det \text{Matrix}. \]

Example:

\[
\begin{bmatrix}
3.0 & 1.0 & 2.0 \\
-5.0 & 7.0 & 2.0 \\
-9.0 & -4.0 & 1.0
\end{bmatrix}
\rightarrow \text{Value} = -134.0
\]

#### Parameters

- **MatrixID** (input_control) .......................... matrix ~> handle
  Matrix handle of the input matrix.
- **MatrixType** (input_control) .......................... string ~> string
  The type of the input matrix.

  **Default value:** ‘general’

19.6. FEATURES

- **Value** (output_control) ................................................................. real → real
  Determinant of the input matrix.

  **Result**
  If the parameters are valid, the operator **determinant_matrix** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

  **Execution Information**
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

- **create_matrix**
  **References**

- **get_size_matrix** ( : : MatrixID : Rows, Columns )
  **Module**
  Get the size of a matrix.
  The operator **get_size_matrix** returns the number of rows **Rows** and columns **Columns** of the input **Matrix**. The input **Matrix** is defined by the matrix handle **MatrixID**.

  **Parameters**
  - **MatrixID** (input_control) ......................................................... matrix → handle
    Matrix handle of the input matrix.
  - **Rows** (output_control) .............................................................. integer → integer
    Number of rows of the matrix.
  - **Columns** (output_control) ........................................................ integer → integer
    Number of columns of the matrix.

  **Result**
  If the parameters are valid, the operator **get_size_matrix** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

  **Execution Information**
  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Processed without parallelization.

- **create_matrix**
  **Possible Predecessors**

- **clear_matrix**
  **Possible Successors**

- **max_matrix** ( : : MatrixID, MaxType : MatrixMaxID )
  **Module**
  Returns the elementwise maximum of a matrix.
The operator \texttt{max\_matrix} returns the maximum values of the elements of the \texttt{Matrix} defined by the matrix handle \texttt{MatrixID}. A new matrix \texttt{MatrixMax} is generated with the result and the matrix handle \texttt{MatrixMaxID} of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator \texttt{get\_full\_matrix}.

The type of maximum determination of the matrix can be selected via the parameter \texttt{MaxType}:

- \textit{'columns'}: The maximum is returned for each column of the \texttt{Matrix} separately. The resulting matrix \texttt{MatrixMax} has one row and the identical number of columns as the input matrix.
  
  Example:
  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0 \\
  \end{bmatrix}
  \quad \text{MaxType} = \text{'columns'}
  \rightarrow \text{MatrixMax} = \begin{bmatrix}
  8.0 & 4.0 & 7.0 \\
  \end{bmatrix}
  \]

- \textit{'rows'}: The maximum is returned for each row of the \texttt{Matrix} separately. The resulting matrix \texttt{MatrixMax} has the identical number of rows as the input matrix and one column.
  
  Example:
  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0 \\
  \end{bmatrix}
  \quad \text{MaxType} = \text{'rows'}
  \rightarrow \text{MatrixMax} = \begin{bmatrix}
  8.0 \\
  7.0 \\
  \end{bmatrix}
  \]

- \textit{'full'}: The maximum is returned using all elements of the \texttt{Matrix}. The resulting matrix \texttt{MatrixMax} has one row and one column.
  
  Example:
  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0 \\
  \end{bmatrix}
  \quad \text{MaxType} = \text{'full'}
  \rightarrow \text{MatrixMax} = \begin{bmatrix}
  8.0 \\
  \end{bmatrix}
  \]

\textbf{Parameters}

\begin{itemize}
  \item \texttt{MatrixID} (input\_control) \texttt{matrix \_handle} \texttt{Matrix handle of the input matrix.}
  \item \texttt{MaxType} (input\_control) \texttt{string \_string} \texttt{Type of maximum determination.}
    \textbf{Default value:} \texttt{'columns'}
    \textbf{List of values:} \texttt{MaxType} \texttt{\in} \{\texttt{'columns'}, \texttt{'rows'}, \texttt{'full'}\}
  \item \texttt{MatrixMaxID} (output\_control) \texttt{matrix \_handle} \texttt{Matrix handle with the maximum values of the input matrix.}
\end{itemize}

\textbf{Result}

If the parameters are valid, the operator \texttt{max\_matrix} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

\textbf{Execution Information}

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

The operator \texttt{mean\_matrix} returns the mean values of the elements of the \texttt{Matrix} defined by the matrix handle \texttt{MatrixID}. A new matrix \texttt{MatrixMean} is generated with the result and the matrix handle \texttt{MatrixMeanID} of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator \texttt{get\_full\_matrix}.

The type of mean determination of the matrix can be selected via the parameter \texttt{MeanType}:

- 'columns': The mean is returned for each column of the \texttt{Matrix} separately. The resulting matrix \texttt{MatrixMean} has one row and the identical number of columns as the input matrix.

  Example:

  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0 
  \end{bmatrix}
  \quad \text{MeanType} = '\text{columns'}
  \]

  \[
  \rightarrow \quad \text{MatrixMean} = \begin{bmatrix}
  1.0 \\
  3.0 \\
  2.0 
  \end{bmatrix}
  \]

- 'rows': The mean is returned for each row of the \texttt{Matrix} separately. The resulting matrix \texttt{MatrixMean} has the identical number of rows as the input matrix and one column.

  Example:

  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0 
  \end{bmatrix}
  \quad \text{MeanType} = '\text{rows'}
  \]

  \[
  \rightarrow \quad \text{MatrixMean} = \begin{bmatrix}
  3.0 \\
  1.0 
  \end{bmatrix}
  \]

- 'full': The mean is returned using all elements of the \texttt{Matrix}. The resulting matrix \texttt{MatrixMean} has one row and one column.

  Example:

  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0 
  \end{bmatrix}
  \quad \text{MeanType} = '\text{full'}
  \]

  \[
  \rightarrow \quad \text{MatrixMean} = \begin{bmatrix}
  2.0 
  \end{bmatrix}
  \]

\begin{verbatim}
MeanType (input_control) : string
  Type of mean determination.
  Default value: 'columns'
  List of values: MeanType ∈ \{'columns', 'rows', 'full'\}
\end{verbatim}

### min_matrix ( : : MatrixID, MinType : MatrixMinID )

Returns the elementwise minimum of a matrix.

The operator `min_matrix` returns the minimum values of the elements of the `Matrix` defined by the matrix handle `MatrixID`. A new matrix `MatrixMin` is generated with the result and the matrix handle `MatrixMinID` of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

The type of minimum determination of the matrix can be selected via the parameter `MinType`:

- **'columns'**: The minimum is returned for each column of the `Matrix` separately. The resulting matrix `MatrixMin` has one row and the identical number of columns as the input matrix.

  Example:

  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0
  \end{bmatrix}
  \text{MinType} = 'columns'
  \]

  \[
  \rightarrow \text{MatrixMin} = \begin{bmatrix}
  -6.0 & 2.0 & -3.0
  \end{bmatrix}
  \]

- **'rows'**: The minimum is returned for each row of the `Matrix` separately. The resulting matrix `MatrixMin` has the identical number of rows as the input matrix and one column.

  Example:

  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0
  \end{bmatrix}
  \text{MinType} = 'rows'
  \]

  \[
  \rightarrow \text{MatrixMin} = \begin{bmatrix}
  -3.0 \\
  -6.0
  \end{bmatrix}
  \]

- **'full'**: The minimum is returned using all elements of the `Matrix`. The resulting matrix `MatrixMin` has one row and one column.

  Example:

  \[
  \text{Matrix} = \begin{bmatrix}
  8.0 & 4.0 & -3.0 \\
  -6.0 & 2.0 & 7.0
  \end{bmatrix}
  \text{MinType} = 'full'
  \]

  \[
  \rightarrow \text{MatrixMin} = \begin{bmatrix}
  -6.0
  \end{bmatrix}
  \]

#### Parameters

- **MatrixID** (input_control) .......................... matrix  \( \rightarrow \) handle
  Matrix handle of the input matrix.
- **MinType** (input_control) .......................... string  \( \rightarrow \) string
  Type of minimum determination.
  **Default value**: 'columns'
  **List of values**: MinType \( \in \{ \text{'columns'}, \text{'rows'}, \text{'full'} \} \)
- **MatrixMinID** (output_control) .......................... matrix  \( \rightarrow \) handle
  Matrix handle with the minimum values of the input matrix.
Result

If the parameters are valid, the operator `min_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Module

Foundation

`norm_matrix (: : MatrixID, NormType : Value )`

Norm of a matrix.

The operator `norm_matrix` computes the norm of the elements of the matrix defined by the matrix handle `MatrixID`. The return value is a floating point number.

The type of norming of the matrix can be selected via the parameter `NormType`:

'frobenius-norm': The Frobenius norm is computed. The formula for the calculation of the result is:

\[ Value = \sqrt{\sum_{i=0}^{m-1} \sum_{j=0}^{n-1} |Matrix_{ij}|^2} \]

with \( m \) = number of rows and \( n \) = number of columns of the matrix.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\end{bmatrix}
\rightarrow Value = 10.0
\]

'infinity-norm': The infinity norm is computed. The result is the largest value of the sum of the absolute values of the elements of the rows. The formula for the calculation is:

\[ Value = \max_{i=0,m-1} \left( \sum_{j=0}^{n-1} |Matrix_{ij}| \right) \]

with \( m \) = number of rows and \( n \) = number of columns of the matrix.

Example:

\[
\begin{bmatrix}
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\end{bmatrix}
\rightarrow Value = 11.0
\]

'1-norm': The 1-norm is computed. The result is the largest value of the sum of the absolute values of the elements of the columns. The formula for the calculation is:
\[
\text{Value} = \max_{j=0, n-1} \sum_{i=0}^{m-1} |\text{Matrix}_{ij}|
\]

with \(m\) = number of rows and \(n\) = number of columns of the Matrix.

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\end{bmatrix} \Rightarrow \text{Value} = 14.0
\]

'2-norm': The 2-norm is computed. The result is the largest singular value of the Matrix. The formula for the calculation of the result is:

\[
\text{Value} = \max(\text{singular values (Matrix)})
\]

Example:

\[
\text{Matrix} = \begin{bmatrix}
3.0 & 1.0 \\
4.0 & -3.0 \\
-7.0 & 4.0
\end{bmatrix} \Rightarrow \text{Value} = 9.7006
\]

**Parameters**

- **MatrixID** (input_control) 
  Matrix handle of the input matrix.

- **NormType** (input_control)
  Type of norm.
  Default value: '2-norm'
  List of values: NormType ∈ {'2-norm', '1-norm', 'infinity-norm', 'frobenius-norm'}

- **Value** (output_control)
  Norm of the input matrix.

**Result**

If the parameters are valid, the operator `norm_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Module**

`sum_matrix ( : : MatrixID, SumType : MatrixSumID )`

Returns the elementwise sum of a matrix.
The operator `sum_matrix` returns the sum of the elements of the Matrix defined by the matrix handle `MatrixID`. A new matrix `MatrixSum` is generated with the result and the matrix handle `MatrixSumID` of this matrix is returned. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`. The type of sum determination of the matrix can be selected via the parameter `SumType`:

'columns': The sum is returned for each column of the Matrix separately. The resulting matrix `MatrixSum` has one row and the identical number of columns as the input matrix.

Example:

\[
\begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}
\]

`SumType = 'columns'`

\[
\begin{bmatrix}
2.0 & 6.0 & 4.0
\end{bmatrix}
\]

'rows': The sum is returned for each row of the Matrix separately. The resulting matrix `MatrixSum` has the identical number of rows as the input matrix and one column.

Example:

\[
\begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}
\]

`SumType = 'rows'`

\[
\begin{bmatrix}
9.0 \\
3.0
\end{bmatrix}
\]

'full': The sum is returned using all elements of the Matrix. The resulting matrix `MatrixSum` has one row and one column.

Example:

\[
\begin{bmatrix}
8.0 & 4.0 & -3.0 \\
-6.0 & 2.0 & 7.0
\end{bmatrix}
\]

`SumType = 'full'`

\[
\begin{bmatrix}
12.0
\end{bmatrix}
\]

### Parameters

- `MatrixID` (input_control) ................................. matrix  \(\rightarrow\) handle
  Matrix handle of the input matrix.

- `SumType` (input_control) ................................. string  \(\rightarrow\) string
  Type of summation.
  
  **Default value:** 'columns'
  
  **List of values:** `SumType` \(\in\) \{'columns', 'rows', 'full'\}

- `MatrixSumID` (output_control) ............................ matrix  \(\rightarrow\) handle
  Matrix handle with the sum of the input matrix.

### Result

If the parameters are valid, the operator `sum_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

19.7 File

```cpp
deserialize_matrix ( : : SerializedItemHandle : MatrixID )
```

Deserialize a serialized matrix.

deserialize_matrix deserializes a matrix, that was serialized by `serialize_matrix` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized matrix is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created matrix with the handle `MatrixID`. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

**Parameters**

- `SerializedItemHandle` (input_control) serialized_item ~ handle
  Handle of the serialized item.
- `MatrixID` (output_control) matrix ~ handle
  Matrix handle.

**Result**

If the parameters are valid, the operator `deserialize_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`get_full_matrix`

Module

Foundation

```cpp
read_matrix ( : : FileName : MatrixID )
```

Read a matrix from a file.

The operator `read_matrix` reads a matrix, which has been written to the file with `write_matrix`, from the file `FileName`. The default HALCON file extension for the matrix is ‘.mtx’. The format of the file can be binary or ascii. Each row of the file contains one row of a matrix with a number of columns. The columns are separated with white spaces or tabs. Each row must have the same number of columns. Empty lines are ignored.

The reading results are stored in the matrix `Matrix`. The operator returns the matrix handle `MatrixID` of this matrix. Access to the elements of the matrix is possible e.g. with the operator `get_full_matrix`.

**Parameters**

- `FileName` (input_control) `.filename.read` ~ string
  File name.
  **File extension:** `.mtx`
- `MatrixID` (output_control) matrix ~ handle
  Matrix handle.

**Result**

If the file name is valid, the operator `read_matrix` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

**Execution Information**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

get_full_matrix

Module

Foundation

```
serialize_matrix ( : : MatrixID : SerializedItemHandle )
```

Serializes a matrix.

serialize_matrix serializes the data of a matrix (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_matrix is converted to a serialized item. The matrix is defined by the handle MatrixID. The serialized matrix is returned by the handle SerializedItemHandle and can be deserialized by deserialize_matrix.

Parameters

▷ MatrixID (input_control) ......................................................... matrix  \( \sim \) handle
  Matrix handle.
▷ SerializedItemHandle (output_control) ...............................serialized_item  \( \sim \) handle
  Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_matrix returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Possible Predecessors

create_matrix

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_matrix

Module

Foundation

```
write_matrix ( : : MatrixID, FileFormat, FileName : )
```

Write a matrix to a file.

The operator write_matrix writes a matrix to the file FileName. The matrix can be read with read_matrix. The default HALCON file extension for the matrix is 'mtx'. The format of the file can be selected via the parameter FileFormat. The following values are supported: 'binary' for a binary file format, and 'ascii' for an ascii text format. In the text format each row of the file contains one row of the matrix. The columns are separated with white spaces. The advantage of using the binary file format instead of the ascii text format is a smaller size of the output file.
Parameters

- **MatrixID** (input_control)  
  Matrix handle of the input matrix.

- **FileFormat** (input_control)  
  Format of the file.
  
  Default value: 'binary'
  
  List of values: FileFormat ∈ {'binary', 'ascii'}

- **FileName** (input_control)  
  File name.
  
  File extension: .mtx

Result

If the file name is valid (write permission), the operator write_matrix returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 20

Morphology

20.1 Gray Values

This chapter describes operators of gray value morphology.

Concept of Gray Value Morphology

Gray value morphology provides a set of operators that allow the non-linear manipulation of gray values in an image, depending on their pixel neighborhood. For instance, morphological gray value operators can be used to smooth or emphasize structural features in images. Unlike the binary operations in Morphology / Region, morphological gray value operators deal with input images that contain pixels with a range of more than one bit. Therefore gray value morphology can be seen as a generalization of region morphology. In the following paragraphs, we will take a closer look at the morphological gray value operators.

Dilation and Erosion of a Grayscale Image

To perform a dilation or erosion, each pixel of the image is assigned a gray value depending on its neighborhood. Area and shape of the neighborhood affecting each pixel are defined by the chosen structuring element with the current pixel being the reference point. Implementing a dilation, every pixel of the input image is assigned the maximum gray value of its neighborhood, respectively the minimum gray value for an erosion. Accordingly, bright areas of the input image are enlarged by gray value dilation, whereas gray value erosion emphasizes dark areas.

These operators can be used to dilate or erode an image:

<table>
<thead>
<tr>
<th>Morphological Operator</th>
<th>Structuring Element</th>
</tr>
</thead>
<tbody>
<tr>
<td>gray_dilation</td>
<td>gray_erosion</td>
</tr>
<tr>
<td>gray_dilation_rect</td>
<td>gray_erosion_rect</td>
</tr>
<tr>
<td>gray_dilation_shape</td>
<td>gray_erosion_shape</td>
</tr>
</tbody>
</table>

1) Original gray value image, 2) structuring element with reference point in the origin, 3) result of eroding the input image, 4) result of dilating the input image.
Morphological grayscale operations are often part of the preprocessing of images before information can be extracted properly. The following example displays a case where a gray value erosion is necessary to read data code symbols. In order to fit a data model used for decoding, the gaps between the code elements in the image need to be reduced by enlarging local minima in a square shape. Therefore a gray value erosion is performed, using an adequately sized rectangle as the structuring element. The rectangle size depends on the data model created with `create_data_code_2d_model`, where the acceptable module gap size is determined.

(1) Image of coded object, (2) erosion with square structuring element, (3) applying data model for decoding.
These images are from the example program `2d_data_codes_minimize_module_gaps.hdev`.

Opening and Closing
Gray value opening and gray value closing operators each are a combination of the operators explained above. Closing is a dilation followed by an erosion, while for an opening an erosion precedes a dilation operation. As seen in the example images, `gray_closing` reduces or even removes parts of the image that are darker than their neighborhood whereas `gray_opening` reduces lighter areas. Furthermore, using a suited structuring element you can preserve shapes while removing unwanted image artifacts.

(1) Original gray value image, (2) structuring element with reference point in the origin, (3) result of closing the input image, (4) result of opening the input image.

Further Operators
To take a closer look at areas that are affected by gray value opening or closing, you can perform a `gray_tophat` or `gray_bothat` transformation. The resulting image displays the difference between the original image and the opening respectively closing of an image. You can also use these operators to detect structures that match the shape of the structuring element.

The `gray_range_rect` operator gives you the opportunity to detect fine structures on homogeneous surfaces by visualizing the extent of local variations in pixel values.
20.1. Gray Values

By applying the `gray_range_rect` operator you can perform a mitigated form of a gray value opening or closing operation. You can control the transformation by adjusting the parameter `ModePercent`.

Dual rank operations: (1) `ModePercent = 0` (equals opening), (2) `ModePercent = 25`, (3) `ModePercent = 50` (equals median), (4) `ModePercent = 75`, (5) `ModePercent = 100` (equals closing).

Glossary

In the following list, the most important terms that are used in the context of Morphology are described.

**Non-linear operator** Operator which does not necessarily preserve structures of the input image

**Structuring element** Region which is used to scan the input image.

```
dual_rank(Image : ImageRank : MaskType, Radius, ModePercent, Margin : )
```

*Opening, Median and Closing with circle or rectangle mask.*

The operator `dual_rank` carries out a non-linear transformation of the gray values of all input images (`Image`). Circles or squares can be used as structuring elements. The operator `dual_rank` effects two consecutive calls of `rank_image`. At the first call the range gray value is calculated with the indicated range (`ModePercent`). The result of this calculation is the input of a further call of `rank_image`, this time using the range value `100−ModePercent`.

When filtering different parameters for border treatment (`Margin`) can be chosen:

- **gray value** Pixels outside of the image edges are assumed to be constant (with the indicated gray value).
- **'continued'** Continuation of edge pixels.
- **'cyclic'** Cyclic continuation of image edges.
- **'mirrored'** Reflection of pixels at the image edges.
A range filtering is calculated according to the following scheme: The indicated mask is put over the image to be filtered in such a way that the center of the mask touches all pixels once. For each of these pixels all neighboring pixels covered by the mask are sorted in an ascending sequence corresponding to their gray values. Each sorted sequence of gray values contains the same number of gray values like the mask has image points. The n-th highest element, (\(=\) ModePercent, rank values between 0...100 in percent) is selected and set as result gray value in the corresponding result image.

If ModePercent is 0, then the operator equals to the gray value opening (\(gray\_opening\)). If ModePercent is 50, the operator results in the median filter, which is applied twice (\(median\_image\)). The ModePercent 100 in dual_rank means that it calculates the gray value closing (\(gray\_closing\)). Choosing parameter values inside this range results in a smooth transformation of these operators.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention
Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) .................. (multichannel-image-array) \(\sim\) object : byte / int2 / uint2 / int4 / real
  Image to be filtered.
- **ImageRank** (output_object) ............ multichannel-image-array \(\sim\) object : byte / int2 / uint2 / int4 / real
  Filtered Image.
- **MaskType** (input_control) .................. string \(\sim\) string
  Shape of the mask.
  Default value: 'circle'
  List of values: MaskType \(\in\) {'circle', 'square'}
- **Radius** (input_control) .................. integer \(\sim\) integer
  Radius of the filter mask.
  Default value: 1
  Suggested values: Radius \(\in\) {1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 15, 19, 25, 31, 39, 47, 59}
  Typical range of values: \(1 \leq\) Radius \(\leq\) 101
  Minimum increment: 1
  Recommended increment: 2
- **ModePercent** (input_control) .................. integer \(\sim\) integer
  Filter Mode: 0 corresponds to a gray value opening , 50 corresponds to a median and 100 to a gray values closing.
  Default value: 10
  Suggested values: ModePercent \(\in\) {0, 2, 5, 10, 15, 20, 40, 50, 60, 80, 85, 90, 95, 98, 100}
  Typical range of values: \(0 \leq\) ModePercent \(\leq\) 100
  Minimum increment: 1
  Recommended increment: 2
- **Margin** (input_control) .................. string \(\sim\) string / integer / real
  Border treatment.
  Default value: 'mirrored'
  Suggested values: Margin \(\in\) {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Example

```
read_image(Image,'fabrik')
dual_rank(Image,ImageOpening,'circle',10,10,'mirrored')
dev_display(ImageOpening)
```

Complexity
For each pixel: \(O(\sqrt{F} \times 10)\) with \(F\) = area of the structuring element.

Result
If the parameter values are correct the operator dual_rank returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system (‘no_object_result’,<Result>). If necessary an exception is raised.

Execution Information

HALCON/HDevelop Reference Manual, 2020-11-10

Module

```
gen_disc_se ( : SE : Type, Width, Height, Smax : )
```

Generate ellipsoidal structuring elements for gray morphology.

gen_disc_se generates an ellipsoidal structuring element (SE) for gray morphology of images. The parameter Type determines the image type. It must match the image type of the image to be processed in subsequent operator calls using this structuring element. The parameters Width and Height determine the length of the two major axes of the ellipse. The value of Smax determines the maximum gray value of the structuring element. For the generation of arbitrary structuring elements, see read_gray_se. The structuring element can be saved as image with the help of the operator write_image. However, take care to use an image format that supports alpha channels to save the shape of the structuring element such as ‘tiff’, ‘jp2’ or ‘png’. These files can then be loaded again with the operator read_image.

Parameters

- **SE** (output_object) ................................. image  ~> object : byte / uint2 / real
  Generated structuring element.
- **Type** (input_control) ............................... string  ~> string
  Pixel type.
  Default value: 'byte'
  List of values: Type ∈ {'byte', 'uint2', 'real'}
- **Width** (input_control) .............................. integer  ~> integer
  Width of the structuring element.
  Default value: 5
  Suggested values: Width ∈ {0, 1, 2, 3, 4, 5, 10, 15, 20}
  Typical range of values: 0 ≤ Width ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1
- **Height** (input_control) ............................ integer  ~> integer
  Height of the structuring element.
  Default value: 5
  Suggested values: Height ∈ {0, 1, 2, 3, 4, 5, 10, 15, 20}
  Typical range of values: 0 ≤ Height ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1
Smax (input_control) .............................................. number \(\sim\) real / integer
Maximum gray value of the structuring element.

Default value: 0

Suggested values: \(\text{Smax} \in \{0, 1, 2, 5, 10, 20, 30, 40\}\)

\[
\text{Foundation}
\]

\[
\text{gray_bothat} \quad (\text{Image}, \text{SE} : \text{ImageBotHat} : : )
\]

Perform a gray value bottom hat transformation on an image.

gray_bothat applies a gray value bottom hat transformation to the input image \text{Image} with the structuring element \text{SE}. The image type of the structuring element \text{SE} must match the image type of the input image \text{Image}. The gray value bottom hat transformation of an image \(i\) with a structuring element \(s\) is defined as

\[
\text{bothat}(i, s) = (i \ast s) - i,
\]

i.e., the difference of the closing of the image with \(s\) and the image (see \text{gray_closing}). For the generation of structuring elements, see \text{read_gray_se}.

The gray value erosion is particularly fast for flat structuring elements, i.e. structuring elements with a constant gray level within their domain.

Possible Predecessors

read_gray_se, gen_disc_se, read_image

Possible Successors

threshold

Alternatives

gray_closing

See also

gray_tophat, top_hat, gray_erosion_rect, sub_image

Module

gray_closing ( Image, SE : ImageClosing : : )

Perform a gray value closing on an image.

gray_closing applies a gray value closing to the input image Image with the structuring element SE. The image type of the structuring element SE must match the image type of the input image Image. The gray value closing of an image i with a structuring element s is defined as

\[ i \ast s = (i \oplus s) \ominus \bar{s}, \]

i.e., a dilation of the image with s followed by an erosion with the transposed structuring element (see gray_dilation and gray_erosion). For the generation of structuring elements, see read_gray_se.

The gray value closing is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

Parameters

- **Image** (input_object) .................. (multichannel-image-array) \( \sim \) object : byte / uint2 / real
  Input image.
- **SE** (input_object) .................. singlechannelimage \( \sim \) object : byte / uint2 / real
  Structuring element.
- **ImageClosing** (output_object) .................. (multichannel-image-array) \( \sim \) object : byte / uint2 / real
  Gray-closed image.

Result

gray_closing returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Possible Predecessors

closing, gray_dilation, gray_erosion

Module

Foundation
gray_closing_rect ( Image : ImageClosing : MaskHeight, MaskWidth : )

Perform a gray value closing with a rectangular mask.

gray_closing_rect applies a gray value closing to the input image Image with a rectangular mask of size (MaskHeight, MaskWidth). The resulting image is returned in ImageClosing. If the parameters MaskHeight or MaskWidth are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

The gray value closing of an image $i$ with a rectangular structuring element $s$ is defined as

$$ i \circ s = (i \oplus s) \ominus s , $$

i.e., a dilation of the image with $s$ followed by an erosion with $s$ (see gray_dilation_rect and gray_erosion_rect).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) ........ (multichannel-)image(-array) $\sim$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Input image.

- **ImageClosing** (output_object) ........ (multichannel-)image(-array) $\sim$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Gray-closed image.

- **MaskHeight** (input_control) ..........................................................extent.y $\sim$ integer
  
  Height of the filter mask.

  Default value: 11

  Suggested values: $\text{MaskHeight} \in \{3, 5, 7, 9, 11, 13, 15\}$

  Typical range of values: $3 \leq \text{MaskHeight} \leq 511$

  Minimum increment: 2

  Recommended increment: 2

  Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2

- **MaskWidth** (input_control) ..........................................................extent.x $\sim$ integer
  
  Width of the filter mask.

  Default value: 11

  Suggested values: $\text{MaskWidth} \in \{3, 5, 7, 9, 11, 13, 15\}$

  Typical range of values: $3 \leq \text{MaskWidth} \leq 511$

  Minimum increment: 2

  Recommended increment: 2

  Restriction: odd(MaskWidth) && MaskWidth < width(Image) * 2

Result

gray_closing_rect returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(’no_object_result’,<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

gray_closing, gray_closing_shape
See also  
closing_rectangle, gray_dilation_rect, gray_erosion_rect

Module Foundation

gray_closing_shape ( Image : ImageClosing : MaskHeight, MaskWidth, MaskShape : )

Perform a gray value closing with a selected mask.

gray_closing_shape applies a gray value closing to the input image Image with the structuring element of shape MaskShape. The mask’s offset values are 0 and its horizontal and vertical size is defined by MaskHeight and MaskWidth. The resulting image is returned in ImageClosing.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageClosing is interpolated from the two intermediate images. Therefore, note that gray_closing_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values ‘rhombus’ and ‘octagon’ for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value ’octagon’ for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

The gray value closing of an image $i$ with a structuring element $s$ is defined as

$$ i \ast s = (i \ast s) \ominus s , $$

i.e., a dilation of the image with $s$ followed by an erosion with $s$ (see gray_dilation_shape and gray_erosion_shape).

Attention

Note that gray_closing_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_closing_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) ......................................................... (multichannel-)image(-array)  \( \sim \) object : byte / uint2
  Image for which the minimum gray values are to be calculated.

- **ImageClosing** (output_object) ............................................ (multichannel-)image(-array)  \( \sim \) object : byte / uint2
  Image containing the minimum gray values.

- **MaskHeight** (input_control) .............................................. extent.y  \( \sim \) real / integer
  Height of the filter mask.
  Default value: 11
  Suggested values: MaskHeight ∈ \{3, 5, 7, 9, 11, 13, 15\}
  Typical range of values: 1.0 ≤ MaskHeight ≤ 511.0

- **MaskWidth** (input_control) .............................................. extent.x  \( \sim \) real / integer
  Width of the filter mask.
  Default value: 11
  Suggested values: MaskWidth ∈ \{3, 5, 7, 9, 11, 13, 15\}
  Typical range of values: 1.0 ≤ MaskWidth ≤ 511.0

- **MaskShape** (input_control) ............................................ string  \( \sim \) string
  Shape of the mask.
  Default value: ’octagon’
  List of values: MaskShape ∈ \{’rectangle’, ’rhombus’, ’octagon’\}
**Result**

`gray_closing_shape` returns 2 (H_MSG_TRUE) if all parameters are correct.

**Execution Information**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

**Alternatives**

`gray_closing`  
See also `gray_dilation_shape`, `gray_erosion_shape`, `closing`  

**Module**

Foundation

```plaintext
gray_dilation ( Image, SE : ImageDilation : : )
```

**Perform a gray value dilation on an image.**

`gray_dilation` applies a gray value dilation to the input image `Image` with the structuring element `SE`. The image type of the structuring element `SE` must match the image type of the input image `Image`. The gray value dilation of an image `i` with a structuring element `s` at the pixel position `x` is defined as:

\[
(i \oplus s)(x) = \max \left\{ f(x - z) + s(z) \mid z \in S \right\}
\]

Here, `S` is the domain of the structuring element `s` (see `read_gray_se`).

The gray value dilation is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

**Parameters**

- `Image` (input_object) (multichannel-image-array) \~ object : byte / uint2 / real  
  Input image.
- `SE` (input_object) (singlechannel-image) \~ object : byte / uint2 / real  
  Structuring element.
- `ImageDilation` (output_object) (multichannel-image-array) \~ object : byte / uint2 / real  
  Gray-dilated image.

**Result**

`gray_dilation` returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

---

### gray_dilation_rect

| Image | ImageMax | MaskHeight, MaskWidth |

Determine the maximum gray value within a rectangle.

gray_dilation_rect calculates the maximum gray value of the input image `Image` within a rectangular mask of size `(MaskHeight, MaskWidth)` for each image point. The resulting image is returned in `ImageMax`. If the parameters `MaskHeight` or `MaskWidth` are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

**Attention**

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

**Parameters**

- **Image** (input_object) 
  
  (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Image for which the maximum gray values are to be calculated.

- **ImageMax** (output_object) 
  
  (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Image containing the maximum gray values.

- **MaskHeight** (input_control) 
  
  Height of the filter mask.

  **Default value:** 11

  **Suggested values:** `MaskHeight` $\in \{3, 5, 7, 9, 11, 13, 15\}$

  **Typical range of values:** $3 \leq MaskHeight \leq 511$

  **Minimum increment:** 2

  **Recommended increment:** 2

  **Restriction:** `odd(MaskHeight) && MaskHeight < height(Image) * 2`

- **MaskWidth** (input_control) 
  
  Width of the filter mask.

  **Default value:** 11

  **Suggested values:** `MaskWidth` $\in \{3, 5, 7, 9, 11, 13, 15\}$

  **Typical range of values:** $3 \leq MaskWidth \leq 511$

  **Minimum increment:** 2

  **Recommended increment:** 2

  **Restriction:** `odd(MaskWidth) && MaskWidth < width(Image) * 2`

**Result**

`gray_dilation_rect` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system(‘no_object_result’, <Result>)`. If necessary, an exception is raised.

**Execution Information**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on domain level.

Module Foundation

gray_dilation_shape ( Image : ImageMax : MaskHeight, MaskWidth, MaskShape : )

Determine the maximum gray value within a selected mask.

gray_dilation_shape calculates the maximum gray value of the input image Image within a mask of shape MaskShape, vertical size MaskHeight and horizontal size MaskWidth for each image point. The resulting image is returned in ImageMax.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageMax is interpolated from the two intermediate images. Therefore, note that gray_dilation_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values ’rhombus’ and ’octagon’ for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value ’octagon’ for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

Attention Note that gray_dilation_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_dilation_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ Image (input_object) ..............................................(multichannel-)image(-array) \( \leadsto \) object : byte / uint2
Image for which the maximum gray values are to be calculated.

▷ ImageMax (output_object) .................................(multichannel-)image(-array) \( \leadsto \) object : byte / uint2
Image containing the maximum gray values.

▷ MaskHeight (input_control) ..............................extent.y \( \leadsto \) real / integer
Height of the filter mask.
    Default value: 11
    Suggested values: MaskHeight \( \in \{3, 5, 7, 9, 11, 13, 15\} \)
    Typical range of values: \( 1.0 \leq \) MaskHeight

▷ MaskWidth (input_control) ..............................extent.x \( \leadsto \) real / integer
Width of the filter mask.
    Default value: 11
    Suggested values: MaskWidth \( \in \{3, 5, 7, 9, 11, 13, 15\} \)
    Typical range of values: \( 1.0 \leq \) MaskWidth

▷ MaskShape (input_control) .......................................................... string \( \leadsto \) string
Shape of the mask.
    Default value: ’octagon’
    List of values: MaskShape \( \in \{ ’rectangle’, ’rhombus’, ’octagon’ \} \)
gray_dilation_shape returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

• Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on domain level.

Module

Foundation

gray_erosion ( Image, SE : ImageErosion : )

Perform a gray value erosion on an image.

gray_erosion applies a gray value erosion to the input image Image with the structuring element SE. The image type of the structuring element SE must match the image type of the input image Image. The gray value erosion of an image \( i \) with a structuring element \( s \) at the pixel position \( x \) is defined as:

\[
(i \ominus s)(x) = \min\{f(x+z) - s(z)|z \in S\}
\]

Here, \( S \) is the domain of the structuring element \( s \) (see read_gray_se).

The gray value erosion is particularly fast for flat structuring elements, i.e., structuring elements with a constant gray level within their domain.

Parameters

\( \triangleright \) Image (input_object) ....................... (multichannel-)image(-array) \( \rightsquigarrow \) object : byte / uint2 / real
Input image.
\( \triangleright \) SE (input_object) ................................. singlechannelimage \( \rightsquigarrow \) object : byte / uint2 / real
Structuring element.
\( \triangleright \) ImageErosion (output_object) ............... (multichannel-)image(-array) \( \rightsquigarrow \) object : byte / uint2 / real
Gray-eroded image.

Result

gray_erosion returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.
• Automatically parallelized on channel level.
• Automatically parallelized on internal data level.
**gray_erosion_rect** ( Image : ImageMin : MaskHeight, MaskWidth : )

Determine the minimum gray value within a rectangle.

gray_erosion_rect calculates the minimum gray value of the input image Image within a rectangular mask of size (MaskHeight, MaskWidth) for each image point. The resulting image is returned in ImageMin. If the parameters MaskHeight or MaskWidth are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

**Attention**

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

**Parameters**

- **Image** (input_object) ...... (multichannel-)image(-array) ~ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  Image for which the minimum gray values are to be calculated.

- **ImageMin** (output_object) ...... (multichannel-)image(-array) ~ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  Image containing the minimum gray values.

- **MaskHeight** (input_control) .......................................................... extent.y ~ integer
  Height of the filter mask.
  **Default value:** 11
  **Suggested values:** MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}
  **Typical range of values:** 3 ≤ MaskHeight ≤ 511 (lin)
  **Minimum increment:** 2
  **Recommended increment:** 2
  **Restriction:** odd(MaskHeight) && MaskHeight < height(Image) * 2

- **MaskWidth** (input_control) .......................................................... extent.x ~ integer
  Width of the filter mask.
  **Default value:** 11
  **Suggested values:** MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}
  **Typical range of values:** 3 ≤ MaskWidth ≤ 511 (lin)
  **Minimum increment:** 2
  **Recommended increment:** 2
  **Restriction:** odd(MaskWidth) && MaskWidth < width(Image) * 2

**Result**

gray_erosion_rect returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

**Execution Information**

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

**gray_opening_rect** ( Image : ImageOpening : MaskHeight, 
MaskWidth : )

Perform a gray value opening with a rectangular mask.

gray_opening_rect applies a gray value opening to the input image Image with a rectangular mask of size (MaskHeight, MaskWidth). The resulting image is returned in ImageOpening. If the parameters MaskHeight or MaskWidth are even, they are changed to the next larger odd value. At the border of the image the gray values are mirrored.

The gray value opening of an image $i$ with a rectangular structuring element $s$ is defined as

$$i \circ s = (i \ominus s) \oplus s,$$

i.e., an erosion of the image with $s$ followed by a dilation with $s$ (see gray_erosion_rect and gray_dilation_rect).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- **Image** (input_object) ...... (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Input image.

- **ImageOpening** (output_object) ...... (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / uint2 / int2 / int4 / real
  
  Gray-opened image.

- **MaskHeight** (input_control) .............................................................. extent.y $\leadsto$ integer
  
  Height of the filter mask.
  
  **Default value:** 11
  
  **Suggested values:** MaskHeight $\in$ {3, 5, 7, 9, 11, 13, 15}
  
  **Typical range of values:** $3 \leq$ MaskHeight $\leq$ 511
  
  **Minimum increment:** 2
  
  **Recommended increment:** 2
  
  **Restriction:** odd(MaskHeight) && MaskHeight < height(Image) * 2

- **MaskWidth** (input_control) .............................................................. extent.x $\leadsto$ integer
  
  Width of the filter mask.
  
  **Default value:** 11
  
  **Suggested values:** MaskWidth $\in$ {3, 5, 7, 9, 11, 13, 15}
  
  **Typical range of values:** $3 \leq$ MaskWidth $\leq$ 511
  
  **Minimum increment:** 2
  
  **Recommended increment:** 2
  
  **Restriction:** odd(MaskWidth) && MaskWidth < width(Image) * 2

Result

gray_opening_rect returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(‘no_object_result’,<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).

**gray_opening_shape** ( Image : ImageOpening : MaskHeight, MaskWidth, MaskShape : )

*Perform a gray value opening with a selected mask.*

gray_opening_shape applies a gray value opening to the input image Image with the structuring element of shape MaskShape. The mask’s offset values are 0 and its horizontal and vertical size is defined by MaskHeight and MaskWidth. The resulting image is returned in ImageOpening.

If the parameters MaskHeight or MaskWidth are of the type integer and are even, they are changed to the next larger odd value. In contrast, if at least one of the two parameters is of the type float, the input image Image is transformed with both the next larger and the next smaller odd mask size, and the output image ImageOpening is interpolated from the two intermediate images. Therefore, note that gray_opening_shape returns different results for mask sizes of, e.g., 4 and 4.0!

In case of the values ‘rhombus’ and ‘octagon’ for the MaskShape control parameter, MaskHeight and MaskWidth must be equal. The parameter value ‘octagon’ for MaskShape denotes an equilateral octagonal mask which is a suitable approximation for a circular structure. At the border of the image the gray values are mirrored.

The gray value opening of an image \(i\) with a structuring element \(s\) is defined as

\[i \circ s = (i \ominus s) \oplus s,\]

i.e., an erosion of the image with \(s\) followed by a dilation with \(s\) (see gray_erosion_shape and gray_dilation_shape).

---

**Attention**

Note that gray_opening_shape requires considerably more time for mask sizes of type float than for mask sizes of type integer. This is especially true for rectangular masks with different width and height!

gray_opening_shape can be executed on OpenCL devices. In case of mask sizes of type float the result can vary slightly from the CPU as the interpolation is calculated in single precision on the OpenCL device.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

### gray_range_rect ( Image : ImageResult : MaskHeight, MaskWidth : )

Determine the gray value range within a rectangle.

\(\text{gray_range_rect}\) calculates the gray value range, i.e., the difference \((\max - \min)\) of the maximum and minimum gray values, of the input image \(\text{Image}\) within a rectangular mask of size \((\text{MaskHeight}, \text{MaskWidth})\) for each image point. The resulting image is returned in \(\text{ImageResult}\). If the parameters \(\text{MaskHeight}\) or \(\text{MaskWidth}\) are even, they are changed to the next smaller odd value. At the border of the image the gray values are mirrored.

**Attention**

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter **Filters**.

**Parameters**

- **Image** (input_object) ............ (multichannel-image-array)  \(\sim\) object : byte / cyclic / uint2 / int2 / int4 / real
  Image for which the gray value range is to be calculated.

- **ImageResult** (output_object) ....... (multichannel-image-array)  \(\sim\) object : byte / cyclic / uint2 / int2 / int4 / real
  Image containing the gray value range.

- **MaskHeight** (input_control) ................................................................. extent.y  \(\sim\) integer
  Height of the filter mask.
  Default value: 11
  Suggested values: \(\text{MaskHeight} \in \{3, 5, 7, 9, 11, 13, 15\}\)
  Typical range of values: \(3 \leq \text{MaskHeight} \leq 511\) (lin)
  Minimum increment: 2
  Recommended increment: 2
  Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2
**MaskWidth** (input_control) ...................................................... extent.x  \(\sim\) integer
Width of the filter mask.

Default value: 11

Suggested values: \(\text{MaskWidth} \in \{3, 5, 7, 9, 11, 13, 15\}\)

Typical range of values: \(3 \leq \text{MaskWidth} \leq 511\) (lin)

Minimum increment: 2

Recommended increment: 2

Restriction: \(\text{odd(MaskWidth)} \&\& \text{MaskWidth} < \text{width(Image)} \times 2\)

**gray_range_rect** returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

---

**Execution Information**

---

**Foundation**

---

---

**gray_tophat** ( Image, SE : ImageTopHat : : )

Perform a gray value top hat transformation on an image.

gray_tophat applies a gray value top hat transformation to the input image *Image* with the structuring element *SE*. The image type of the structuring element *SE* must match the image type of the input image *Image*. The gray value top hat transformation of an image \(i\) with a structuring element \(s\) is defined as

\[
\text{tophat}(i, s) = i - (i \circ s),
\]

i.e., the difference of the image and its opening with \(s\) (see *gray_opening*). For the generation of structuring elements, see *read_gray_se*.

The top hat transformation is particularly fast for flat structuring elements, i.e. structuring elements with a constant gray level within their domain.

---

**Parameters**

- **Image** (input_object) ........................................... (multichannel-image-array) \(\sim\) object : byte / uint2 / real
Input image.
- **SE** (input_object) .................................................... singlechannelimage \(\sim\) object : byte / uint2 / real
Structuring element.
- **ImageTopHat** (output_object) ........................... (multichannel-image-array) \(\sim\) object : byte / uint2 / real
Top hat image.

---

gray_tophat returns 2 (H_MSG_TRUE) if the structuring element is not the empty region. Otherwise, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module
Foundation

read_gray_se ( : SE : FileName : )

Load a structuring element for gray morphology.

read_gray_se loads a structuring element for gray morphology from a file. The file names of these structuring elements must end in '.gse' (for gray-scale structuring element). This suffix is automatically appended by read_gray_se to the passed file name, and thus must not be passed. The structuring element’s data must be contained in the file in the following format: The first line specifies the data type of the structuring element as 'byte', 'uint2' or 'real' (without enclosing quotes). It must match the image type of the image to be processed in subsequent operator calls using this structuring element. The following two numbers in the file determine the width and height of the structuring element and determine a rectangle enclosing the structuring element. Both values must be greater than 0. Then the number of chords of the region to be defined follows. Then the chords themselves follow: Each chord is defined by the row of the chord (L), the column begin (CB) and the column end (CE), separated by a space between them. Then values follow that are regarded as the corresponding values for gray morphology (their number depends on the defined width and height of the structuring element). Values that will not be part of the region of the structuring element (because no chord is defined for this points) must not be omitted. Nevertheless they will be ignored in the resulting structuring element. Structuring elements are stored internally as images with the data type specified above. Normal images can also be used as structuring elements, where the region of the image defines the shape of the structuring element. However, take care not to use too large images, since the runtime is proportional to the area of the image multiplied by the area of the structuring element. Flat structuring elements (i.e. elements with constant gray values) will be executed particularly fast though. The origin of the structuring element lies at half of the defined width and height. For even dimensions the origin will be rounded towards the upper left corner. The structuring element can be saved as image with the help of the operator write_image. However, take care to use an image format that supports alpha channels to save the shape of the structuring element such as 'tiff', 'jp2' or 'png'. These files can then be loaded again with the operator read_image.

Parameters

▷ SE (output_object) ................................................. image ~ object : byte / uint2 / real
Generated structuring element.

▷ FileName (input_control) ........................................ filename.read ~ string
Name of the file containing the structuring element.

File extension: .gse

Example

* Load a byte structuring element of width 3 and height 3 that
* consists of 3 chords at lines 0 (from x=1 to x=1), 1 (from x=0
to x=2) and 2 (from x=1 to x=1). The (used) grayvalues are
* 0, 0, 1, 0, 0 .

HALCON 20.11.0.0
* contents of file 'isod4.gse':

* byte
*   3 3
*   3
*   0 1 1
*   1 0 2
*   2 1 1
*   -1 0 -1
*   0 1 0
*   -1 0 -1

read_gray_se (SE, environment('HALCONROOT')+'/filter/isod4')

---

Result

read_gray_se returns 2 (H_MSG_TRUE) if all parameters are correct. Otherwise, an exception is raised.

---

Execution Information

20.2 Region

This chapter describes operators of region morphology.

Concept of Region Morphology

Region morphology provides a set of morphological operators that allow to modify or describe the shape of a region. The morphological operators can be used, for example, to connect or disconnect adjacent regions or to smooth the boundary of a region. In the following, we will take a closer look at the morphological operators.

Dilation and Erosion

To dilate or erode an input region, a structuring element is applied to the input region. This structuring element is scanned over the image line-by-line. During dilation the reference point of the structuring element is added to the resulting region whenever the structuring element and the input region have at least one pixel in common. This results in an enlarged region, as shown in the image below. Erosion reduces the area of the input region because the reference point is only added to the resulting region if the structuring element lies completely within the input region. As a result, erosion can alternatively be used to find objects.
20.2. REGION

(1) Image with input region, (2) structuring element with reference point in the origin, (3) result of dilating the input region, (4) result of eroding the input region.

These operators can be used to dilate or erode a region:

</table>

Note that Minkowski addition and dilation are identical if the structuring element is symmetric. The same applies to Minkowski subtraction and erosion. Erosion can be used to separate objects that are attached to each other. In the following, the steps that are required to separate objects are described briefly.

First, the objects of the image must be segmented, for example by using the operator threshold. Next, the operator connection is used to get multiple regions instead of a single region. As you can see in the image (3) below, the result of the connection is unsatisfactory because several objects are merged.

This problem can be solved using erosion. As mentioned above, erosion reduces the area of the input region. Thus, if erosion is applied prior to the operator connection, the regions are separated as desired. Lastly, dilation is applied on the separated regions to approximately get the original shape back.
Opening and Closing

Both operators generate the resulting region by combining dilation and erosion. Opening is an erosion followed by a dilation. It is useful to eliminate small unwanted structures. Closing is the opposite of opening, i.e., a dilation followed by an erosion. The closing operator is able to close small gaps, as shown below.

These operators can be used to open or close a region:

Further Operators

In addition to the operators mentioned above, you can use top_hat to get the difference between the input region and the result of the opening, or bottom_hat to get the difference between the result of the closing and the input region. Furthermore, you can calculate the boundary of a region with the operator boundary.

Glossary

In the following list, the most important terms that are used in the context of Morphology are described.

- **input region** Region which is modified by morphological operators.
- **structuring element** Region which is used to scan the input region.

```
bottom_hat ( Region, StructElement : RegionBottomHat : )
```

Compute the bottom hat of regions.
bottom_hat computes the closing of Region with StructElement. The difference between the result of the closing and the original region is called the bottom hat. In contrast to closing, which merges regions under certain circumstances, bottom_hat computes the regions generated by such a merge.

The position of StructElement is meaningless, since a closing operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- Region (input_object) ................................. region(-array)  ~ object
  Regions to be processed.
- StructElement (input_object) ........................ region  ~ object
  Structuring element (position independent).
- RegionBottomHat (output_object) .................... region(-array)  ~ object
  Result of the bottom hat operator.

Example

read_image (Image, 'brake_disk/brake_disk_bike_01')
threshold (Image, Regions, 128, 255)
gen_circle (Circle, 40, 40, 20)
bottom_hat (Regions, Circle, RegionBottomHat)

Result

bottom_hat returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm,
gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region,
gen_region_points, gen_region_polygon_filled

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

closing, difference

Module

Foundation
boundary ( Region : RegionBorder : BoundaryType : )

Reduce a region to its boundary.
boundary computes the boundary of each input region in Region and returns them in RegionBorder. The parameter BoundaryType determines the type of boundary computation.

The contour computation is done using morphological operations. The resulting output regions consist only of the minimal border of the input regions. Their positions depend on the value of BoundaryType, accepting the following values:

- 'inner': The contour lies within the original region.
- 'inner_filled': The contour lies within the original region, holes in the interior of the input region are suppressed. Due to algorithm optimization this contours may slightly differ from corresponding ones obtained with 'inner'.
- 'outer': The contour is one pixel outside of the original region.

Parameters

- **Region** (input_object) region(-array) ~ object
  Regions for which the boundary is to be computed.
- **RegionBorder** (output_object) region(-array) ~ object
  Resulting boundaries.
- **BoundaryType** (input_control) string ~ string
  Boundary type.
  Default value: 'inner'
  List of values: BoundaryType ∈ {'inner', 'outer', 'inner_filled'}

Example

```cpp
#include "HalconCpp.h"
using namespace Halcon;

main()
{
  HWindow w;
  HRegion circ1 = HRegion::GenCircle (20, 10, 10.5);

  circ1.Display (w);
  w.Click ();

  HRegion marg1 = circ1.Boundary ("inner");
  w.SetColor ("red");
  marg1.Display (w);
  w.Click ();
  return(0);
}
```

Complexity

Let \( A \) be the area of the input region. Then the runtime complexity for one region is

\[ O(3\sqrt{A}) \.

Result

boundary returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  `set_system('no_object_result',<RegionResult>)`
• empty region:
  
```
  set_system('empty_region_result',<RegionResult>)
```

Otherwise, an exception is raised.

**Module**

Foundation

---

**closing** ( Region, StructElement : RegionClosing : : )

Close a region.

A closing operation is defined as a dilation followed by a Minkowski subtraction. By applying closing to a region, larger structures remain mostly intact, while small gaps between adjacent regions and holes smaller than StructElement are closed, and the regions’ boundaries are smoothed. All closing variants share the property that separate regions are not merged, but remain separate objects. The position of StructElement is meaningless, since a closing operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

---

**Attention**

Closing is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

---

**Parameters**

- **Region** (input_object) .............................. region(-array) ~ object
  Regions to be closed.

- **StructElement** (input_object) ......................... region ~ object
  Structuring element (position-invariant).

- **RegionClosing** (output_object) ....................... region(-array) ~ object
  Closed regions.

---

**Example**

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
```
cout << "Reproduction of 'closing ()' using " << endl;
cout << "'dilation()' and 'minkowski_sub1()'" << endl;

HByteImage img("monkey");
HWindow w;

HRegion circ = HRegion::GenCircle (10, 10, 1.5);
HRegionArray regs = (img >= 128).Connection();

HRegionArray dilreg = regs.Dilation1 (circ, 1);
HRegionArray minsub = dilreg.MinkowskiSub1 (circ, 1);

img.Display (w); w.Click ();
w.SetColor ("red"); regs.Display (w); w.Click ();
w.SetColor ("green"); dilreg.Display (w); w.Click ();
w.SetColor ("blue"); minsub.Display (w); w.Click ();

return(0);

Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F_1} \cdot \sqrt{F_2})$$

Result

closing returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

* no region:
  set_system('no_object_result',<RegionResult>)
* empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm,
gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region,
gen_region_points, gen_region_polygon_filled

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

closing_circle

Module

Foundation
**closing_circle** ( Region : RegionClosing : Radius : )

**Close a region with a circular structuring element.**

closing_circle behaves analogously to **closing**, i.e., the regions’ boundaries are smoothed and holes within a region which are smaller than the circular structuring element of radius **Radius** are closed. The **closing_circle** operation is defined as a dilation followed by a Minkowski subtraction, both with the same circular structuring element.

**Attention**
closing_circle is applied to each input region separately. If gaps between different regions are to be closed, **union1** or **union2** has to be called first.

**Parameters**

- **Region** (input_object) region(-array) \( \sim \) object
  - Regions to be closed.
- **RegionClosing** (output_object) region(-array) \( \sim \) object
  - Closed regions.
- **Radius** (input_control) real \( \sim \) real / integer
  - Radius of the circular structuring element.
  - Default value: 3.5
  - Suggested values: **Radius** \( \in \{1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5\} \)
  - Typical range of values: \( 0.5 \leq \text{Radius} \leq 511.5 \) (lin)
  - Minimum increment: 1.0
  - Recommended increment: 1.0

**Example**

```c
my_closing_circle(Hobject In, double Radius, Hobject *Out)
{
    Hobject tmp, StructElement;
    gen_circle(StructElement,100.0,100.0,Radius);
    dilation1(In,StructElement,&tmp,1);
    minkowski_sub1(tmp,StructElement,Out,1);
}
```

**Complexity**

Let \( F_1 \) be the area of the input region. Then the runtime complexity for one region is:

\[
O(4 \cdot \sqrt{F_1} \cdot \text{Radius})
\]

**Result**

closing_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:**
  
  ```c
  set_system('no_object_result',<RegionResult>)
  ```

- **empty region:**
  
  ```c
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module
\texttt{Foundation}

\begin{verbatim}
\textbf{closing\_rectangle1 ( Region : RegionClosing : Width, Height : )}
\end{verbatim}

Close a region with a rectangular structuring element.

closing\_rectangle1 performs a \texttt{dilation\_rectangle1} followed by an \texttt{erosion\_rectangle1} on the input region \texttt{Region}. The size of the rectangular structuring element is determined by the parameters \texttt{Width} and \texttt{Height}. As is the case for all closing variants, regions’ boundaries are smoothed and holes within a region which are smaller than the rectangular structuring element are closed.

\textbf{Attention}

closing\_rectangle1 is applied to each input region separately. If gaps between different regions are to be closed, \texttt{union1} or \texttt{union2} has to be called first.

\textbf{Parameters}

\begin{itemize}
  \item \textbf{Region} (input\_object) \texttt{region\_array} \texttt{object}  
  Regions to be closed.
  \item \textbf{RegionClosing} (output\_object) \texttt{region\_array} \texttt{object}  
  Closed regions.
  \item \textbf{Width} (input\_control) \texttt{extent.x} \texttt{integer}  
  Width of the structuring rectangle.
  \textbf{Default value:} 10
  \textbf{Suggested values:} \texttt{Width} \in \{1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200\}
  \textbf{Typical range of values:} 1 \leq \texttt{Width} \leq 511 (lin)
  \textbf{Minimum increment:} 1
  \textbf{Recommended increment:} 1
  \item \textbf{Height} (input\_control) \texttt{extent.y} \texttt{integer}  
  Height of the structuring rectangle.
  \textbf{Default value:} 10
  \textbf{Suggested values:} \texttt{Height} \in \{1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200\}
  \textbf{Typical range of values:} 1 \leq \texttt{Height} \leq 511 (lin)
  \textbf{Minimum increment:} 1
  \textbf{Recommended increment:} 1
\end{itemize}

\textbf{Complexity}

Let \(F1\) be the area of an input region and \(H\) be the height of the rectangle. Then the runtime complexity for one region is:

\[O(2 \cdot \sqrt{F1} \cdot \log_2(H))\ .\]

\textbf{Result}

closing\_rectangle1 returns \texttt{2 (H\_MSG\_TRUE)} if all parameters are correct. The behavior in case of empty or no input region can be set via:

\begin{itemize}
  \item no region:
    \texttt{set\_system(‘no\_object\_result’,<RegionResult>)}
\end{itemize}
• empty region:

```cpp
def set_system('empty_region_result', RegionResult)
```

Otherwise, an exception is raised.

**Module**

**dilation1** ( Region, StructElement : RegionDilation : Iterations : )

---

**Dilate a region.**

The function `dilation1` dilates the input regions with a structuring element. By applying `dilation1` to a region, its boundary gets smoothed. In the process, the area of the region is enlarged. Furthermore, disconnected regions may be merged. Such regions, however, remain logically distinct region. The dilation is a set-theoretic region operation. It uses the union operation.

Let $M$ (StructElement) and $R$ (Region) be two regions, where $M$ is the structuring element and $R$ is the region to be processed. Furthermore, let $m$ be a point in $M$. Then the displacement vector $\vec{v}_m = (dx, dy)$ is defined as the difference of the center of gravity of $M$ and the vector $m$. Let $t_{\vec{v}_m}(R)$ denote the translation of a region $R$ by a vector $\vec{v}$. Then

```
\text{dilation1}(R, M) := \bigcup_{m \in M} t_{-\vec{v}_m}(R)
```

For each point $m$ in $M$ a translation of the region $R$ is performed. The union of all these translations is the dilation of $R$ with $M$. `dilation1` is similar to the operator `minkowski_add1`, the difference is that in `dilation1` the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of $M$.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration $n$. From the above definition it follows that an empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as `gen_circle`, `gen_rectangle1`, `gen_rectangle2`, `genellipse`, `draw_region`, `gen_region_polygon`, `gen_region_points`, etc.

---

**Attention**

A dilation always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator `union1` has to be called first.
**Parameters**

- **Region** (input_object) ~ object
  Regions to be dilated.
- **StructElement** (input_object) ~ object
  Structuring element.
- **RegionDilation** (output_object) ~ object
  Dilated regions.
- **Iterations** (input_control) ~ integer
  Number of iterations.

  **Default value:** 1
  **Suggested values:** Iterations ∈ \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
  **Typical range of values:** 1 ≤ Iterations (lin)
  **Minimum increment:** 1
  **Recommended increment:** 1

**Complexity**

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})
\]

**Result**

dilation1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

**Module**

Foundation

```c
dilation2 ( Region, StructElement : RegionDilation : Row, Column,
            Iterations : )
```

**Dilate a region (using a reference point).**

dilation2 dilates the input regions with a structuring element (StructElement) having the reference point (Row,Column). dilation2 has a similar effect as dilation1, the difference is that the reference point of the
structuring element can be chosen arbitrarily. The parameter \textit{Iterations} determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \).

An empty region is generated in case of an empty structuring element.

Structuring elements (\textit{StructElement}) can be generated with operators such as \textit{gen_circle}, \textit{gen_rectangle1}, \textit{gen_rectangle2}, \textit{gen_ellipse}, \textit{draw_region}, \textit{gen_region_polygon}, \textit{gen_region_points}, etc.

\begin{itemize}
  \item \textbf{Attention}\hfill

Module
Foundation

dilation_circle ( Region : Region : RegionDilation : Radius : )

Dilate a region with a circular structuring element.

dilation_circle applies a Minkowski addition with a circular structuring element to the input regions Region. Because the circular mask is symmetrical, this is identical to a dilation. The size of the circle used as structuring element is determined by Radius.

The operator results in enlarged regions, smoothed region boundaries, and the holes smaller than the circular mask in the interior of the region are closed. It is useful to select only values like 3.5, 5.5, etc. for Radius in order to avoid a translation of a region, because integer radii result in the circle having a non-integer center of gravity which is rounded to the next integer.

Attention
dilation_circle is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

Parameters

- Region (input_object) .................................................. region(-array) \(\sim\) object
  Regions to be dilated.
- RegionDilation (output_object) .............................................. region(-array) \(\sim\) object
  Dilated regions.
- Radius (input_control) ...................................................... real \(\sim\) real / integer
  Radius of the circular structuring element.
  Default value: 3.5
  Suggested values: Radius \(\in\) \{1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5\}
  Typical range of values: 0.5 \(\leq\) Radius \(\leq\) 511.5 (lin)
  Minimum increment: 1.0
  Recommended increment: 1.0

Example

```cpp
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
    cout << "Reproduction of 'dilation_circle ()'" << endl;
    cout << "First = original image " << endl;
    cout << "Blue = after dilation " << endl;
    cout << "Red = before dilation " << endl;
    
    HALCON/HDevelop Reference Manual, 2020-11-10
```
HByteImage img("monkey");
HWindow w;

HRegion circ = HRegion::GenCircle (10, 10, 1.5);
HRegionArray regs = (img >= 128).Connection();
HRegionArray minadd = regs.MinkowskiAdd1 (circ, 1);

img.Display (w); w.Click ();
w.SetColor ("blue"); minadd.Display (w); w.Click ();
w.SetColor ("red"); regs.Display (w); w.Click ();

return(0);

---

Complexity

Let $F_1$ be the area of an input region. Then the runtime complexity for one region is:

$$O(2 \cdot \text{Radius} \cdot \sqrt{F_1})$$

---

Result

dilation_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

**dilation_rectangle1** ( Region : RegionDilation : Width, Height : )

*Dilate a region with a rectangular structuring element.*

dilation_rectangle1 applies a dilation with a rectangular structuring element to the input regions Region. The size of the structuring rectangle is Width $\times$ Height. The operator results in enlarged regions, and the holes smaller than the rectangular mask in the interior of the regions are closed.
dilation_rectangle1 is a very fast operation because the height of the rectangle enters only logarithmically into the runtime complexity, while the width does not enter at all. This leads to excellent runtime efficiency, even in the case of very large rectangles (edge length $> 100$).

Attention

dilation_rectangle1 is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

To enlarge a region by the same amount in all directions, Width and Height must be odd. If this is not the case, the region is dilated by a larger amount at the right or at the bottom, respectively, than at the left or at the top.

Parameters

- **Region** (input_object) ............................... region(-array) $\sim$ object
Regions to be dilated.
- **RegionDilation** (output_object) ................ region(-array) $\sim$ object
Dilated regions.
- **Width** (input_control) ............................... extent.x $\sim$ integer
Width of the structuring rectangle.
  Default value: 11
  Suggested values: $\text{Width} \in \{1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201\}$
  Typical range of values: $1 \leq \text{Width} \leq 511$ (lin)
  Minimum increment: 1
  Recommended increment: 10
- **Height** (input_control) ............................... extent.y $\sim$ integer
Height of the structuring rectangle.
  Default value: 11
  Suggested values: $\text{Height} \in \{1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201\}$
  Typical range of values: $1 \leq \text{Height} \leq 511$ (lin)
  Minimum increment: 1
  Recommended increment: 10

Example

```cpp
#include "HIOStream.h"
#ifndef USE_IOSTREAM_H
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
    cout << "Reproduction of 'dilation_rectangle ()'" << endl;
    cout << "First = original image " << endl;
    cout << "Blue = after dilation " << endl;
    cout << "Red = after segmentation " << endl;

    HByteImage img("monkey");
    HWindow w;

    HRegionArray regs = (img >= 220).Connection();
    HRegionArray dilreg = regs.DilationRectangle1 (2, 4);

    img.Display (w); w.Click ();
    w.SetColor ("blue"); dilreg.Display (w); w.Click ();
    w.SetColor ("red"); regs.Display (w); w.Click ();

    return(0);
}
```

Complexity

Let $F_1$ be the area of an input region and $H$ be the height of the rectangle. Then the runtime complexity for one region is:
\[ O(\sqrt{F} \cdot \text{ld}(H)) \].

dilation_rectangle: returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  \[ \text{set_system('no_object_result',<RegionResult>)} \]

- empty region:
  
  \[ \text{set_system('empty_region_result',<RegionResult>)} \]

Otherwise, an exception is raised.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

### Possible Predecessors

#### erosion1 ( Region, StructElement : RegionErosion : Iterations : )

**Erode a region.**

erosion1 erodes the input regions with a structuring element. By applying erosion1 to a region, its boundary gets smoothed. In the process, the area of the region is reduced. Furthermore, connected regions may be split. Such regions, however, remain logically one region. The erosion is a set-theoretic region operation. It uses the intersection operation.

Let \( M \) (StructElement) and \( R \) (Region) be two regions, where \( M \) is the structuring element and \( R \) is the region to be processed. Furthermore, let \( m \) be a point in \( M \). Then the displacement vector \( \vec{v}_m = (dx, dy) \) is defined as the difference of the center of gravity of \( M \) and the vector \( \vec{m} \). Let \( t_{\vec{v}_m}(R) \) denote the translation of a region \( R \) by a vector \( \vec{v}_m \). Then

\[
\text{erosion1}(R,M) := \bigcap_{m \in M} t_{-\vec{v}_m}(R).
\]

For each point \( m \) in \( M \) a translation of the region \( R \) is performed. The intersection of all these translations is the erosion of \( R \) with \( M \). erosion1 is similar to the operator minkowski_sub1, the difference is that in erosion1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of \( M \).

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \). From the above definition it follows that the maximum region is generated in case of an empty structuring element.
Structuring elements (StructElement) can be generated with operators such as \texttt{gen\_circle}, \texttt{gen\_rectangle1}, \texttt{gen\_rectangle2}, \texttt{gen\_ellipse}, \texttt{draw\_region}, \texttt{gen\_region\_polygon}, \texttt{gen\_region\_points}, etc.

---

**Parameters**

- **Region** (input\_object) \begin{itemize} \item \texttt{region(-array)} \rightarrow \texttt{object} \end{itemize} Regions to be eroded.

- **StructElement** (input\_object) \begin{itemize} \item \texttt{region} \rightarrow \texttt{object} \end{itemize} Structuring element.

- **RegionErosion** (output\_object) \begin{itemize} \item \texttt{region(-array)} \rightarrow \texttt{object} \end{itemize} Eroded regions.

- **Iterations** (input\_control) \begin{itemize} \item \texttt{integer} \rightarrow \texttt{integer} \end{itemize} Number of iterations.

  Default value: 1

  Suggested values: \texttt{Iterations} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}

  Typical range of values: \texttt{1 \leq Iterations (lin)}

  Minimum increment: 1

  Recommended increment: 1

---

**Complexity**

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})
\]

---

**Result**

\texttt{erosion1} returns 2 (\texttt{H\_MSG\_TRUE}) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  \begin{verbatim}
  set_system('no_object_result',<RegionResult>)
  \end{verbatim}

- empty region:
  \begin{verbatim}
  set_system('empty_region_result',<RegionResult>)
  \end{verbatim}

Otherwise, an exception is raised.

---

**Execution Information**

**Module**

Foundation
erosion2 ( Region, StructElement : RegionErosion : Row, Column, Iterations : )

Erode a region (using a reference point).

erosion2 erodes the input regions with a structuring element (StructElement) having the reference point (Row,Column). erosion2 has a similar effect as erosion1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration $n$.

A maximum region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

### Parameters

- **Region** (input_object) ... region(-array) $\rightarrow$ object
  - Regions to be eroded.
- **StructElement** (input_object) ... region(-array) $\rightarrow$ object
  - Structuring element.
- **RegionErosion** (output_object) ... region(-array) $\rightarrow$ object
  - Eroded regions.
- **Row** (input_control) ... point/y $\rightarrow$ integer
  - Row coordinate of the reference point.
  - Default value: 0
  - Typical range of values: $0 \leq \text{Row} \leq 511$ (lin)
  - Minimum increment: 1
  - Recommended increment: 1
- **Column** (input_control) ... point/x $\rightarrow$ integer
  - Column coordinate of the reference point.
  - Default value: 0
  - Typical range of values: $0 \leq \text{Column} \leq 511$ (lin)
  - Minimum increment: 1
  - Recommended increment: 1
- **Iterations** (input_control) ... integer $\rightarrow$ integer
  - Number of iterations.
  - Default value: 1
  - Suggested values: $\text{Iterations} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}$
  - Typical range of values: $1 \leq \text{Iterations}$ (lin)
  - Minimum increment: 1
  - Recommended increment: 1

### Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations}) .$$

### Result

erosion2 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- **no region:**
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- **empty region:**
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors

transpose_region, gen_circle, gen_rectangle2, gen_region_polygon

Foundation

**erosion_circle** ( Region : RegionErosion : Radius : )

Erode a region with a circular structuring element.

erosion_circle applies a Minkowski subtraction with a circular structuring element to the input regions Region. Because the circular mask is symmetrical, this is identical to an erosion. The size of the circle used as structuring element is determined by Radius.

The operator results in reduced regions, smoothed region boundaries, and the regions smaller than the circular mask are eliminated. It is useful to select only values like 3.5, 5.5, etc. for Radius in order to avoid a translation of a region, because integer radii result in a circle having a non-integer center of gravity which is rounded to the next integer.

Parameters

▷ Region (input_object) .......................................................... region(-array)  \sim object
Regions to be eroded.

▷ RegionErosion (output_object) .................................................. region(-array)  \sim object
Eroded regions.

▷ Radius (input_control) .......................................................... real  \sim real / integer
Radius of the circular structuring element.

Default value: 3.5

Suggested values: Radius \in \{1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5\}

Typical range of values: 0.5 \leq \text{Radius} \leq 511.5 \text{ (lin)}

Minimum increment: 1.0

Recommended increment: 1.0

Example

```c++
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
    cout << "Simulation of 'erosion_circle ()'" << endl;
    cout << "First = original image " << endl;
    cout << "Red = after segmentation " << endl;
    cout << "Blue = after erosion " << endl;
```
HByteImage img("monkey");
HWindow w;

HRegion circ = HRegion::GenCircle (10, 10, 1.5);
HRegionArray regs = (img >= 128).Connection();
HRegionArray minsub = regs.MinkowskiSub1 (circ, 1);

img.Display (w); w.Click ();
w.SetColor ("red"); regs.Display (w); w.Click ();
w.SetColor ("blue"); minsub.Display (w); w.Click ();

return(0);
}

Complexity

Let $F_1$ be the area of an input region. Then the runtime complexity for one region is:

$$O(2 \cdot \text{Radius} \cdot \sqrt{F_1}) .$$

Result

erosion_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system('no_object_result',<RegionResult>)
- empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

erosion_rectangle1 ( Region : RegionErosion : Width, Height : )

Erode a region with a rectangular structuring element.

erosion_rectangle1 applies an erosion with a rectangular structuring element to the input regions Region. The size of the structuring rectangle is Width $\times$ Height. The operator results in reduced regions, and the areas smaller than the rectangular mask are eliminated.
erosion_rectangle1 is a very fast operation because the height of the rectangle enters only logarithmically into the runtime complexity, while the width does not enter at all. This leads to excellent runtime efficiency, even in the case of very large rectangles (edge length > 100).

Regions containing small connecting strips between large areas are separated only seemingly. They remain logically one region.

Attention

To reduce a region by the same amount in all directions, \texttt{Width} and \texttt{Height} must be odd. If this is not the case, the region is eroded by a larger amount at the right or at the bottom, respectively, than at the left or at the top.

Parameters

\begin{itemize}
\item \textbf{Region} (input\_object) \hspace{2cm} region(-array) \sim object
\end{itemize}

Regions to be eroded.

\begin{itemize}
\item \textbf{RegionErosion} (output\_object) \hspace{2cm} region(-array) \sim object
\end{itemize}

Eroded regions.

\begin{itemize}
\item \textbf{Width} (input\_control) \hspace{2cm} extent.x \sim integer
\end{itemize}

Width of the structuring rectangle.

Default value: 11

Suggested values: \texttt{Width} \in \{1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201\}

Typical range of values: \(1 \leq \text{Width} \leq 511\) (lin)

Minimum increment: 1

Recommended increment: 1

\begin{itemize}
\item \textbf{Height} (input\_control) \hspace{2cm} extent.y \sim integer
\end{itemize}

Height of the structuring rectangle.

Default value: 11

Suggested values: \texttt{Height} \in \{1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201\}

Typical range of values: \(1 \leq \text{Height} \leq 511\) (lin)

Minimum increment: 1

Recommended increment: 1

Complexity

Let \(F1\) be the area of an input region and \(H\) be the height of the rectangle. Then the runtime complexity for one region is:

\[
O(\sqrt{F1} \cdot \log(H))
\]

Result

erosion_rectangle1 returns 2 (H\_MSG\_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- \texttt{no region:}
  
  \begin{verbatim}
  set_system(‘no\_object\_result’,<RegionResult>)
  \end{verbatim}

- \texttt{empty region:}
  
  \begin{verbatim}
  set_system(‘empty\_region\_result’,<RegionResult>)
  \end{verbatim}

Otherwise, an exception is raised.

Module
Foundation

hit_or_miss ( Region, StructElement1, StructElement2 : RegionHitMiss : Row, Column : )

Hit-or-miss operation for regions.

hit_or_miss performs the hit-or-miss-transformation. First, an erosion with the structuring element StructElement1 is done on the input region Region. Then an erosion with the structuring element StructElement2 is performed on the complement of the input region. The intersection of the two resulting regions is the result RegionHitMiss of hit_or_miss.

The hit-or-miss-transformation selects precisely the points for which the conditions given by the structuring elements StructElement1 and StructElement2 are fulfilled. StructElement1 determines the condition for the foreground pixels, while StructElement2 determines the condition for the background pixels. In order to obtain sensible results, StructElement1 and StructElement2 must fit like key and lock. In any case, StructElement1 and StructElement2 must be disjunct. Row and Column determine the reference point of the structuring elements.

Structuring elements (StructElement1, StructElement2) can be generated by calling operators like gen_region_points, etc.

Parameters

- Region (input_object) region(-array) \( \leadsto \) object
  Regions to be processed.
- StructElement1 (input_object) region \( \leadsto \) object
  Erosion mask for the input regions.
- StructElement2 (input_object) region \( \leadsto \) object
  Erosion mask for the complements of the input regions.
- RegionHitMiss (output_object) region(-array) \( \leadsto \) object
  Result of the hit-or-miss operation.
- Row (input_control) point.y \( \leadsto \) integer
  Row coordinate of the reference point.
    Default value: 16
    Suggested values: Row \( \in \{0, 16, 32, 128, 256\} \)
    Typical range of values: \( 0 \leq \text{Row} \leq 511 \) (lin)
    Minimum increment: 1
    Recommended increment: 1
- Column (input_control) point.x \( \leadsto \) integer
  Column coordinate of the reference point.
    Default value: 16
    Suggested values: Column \( \in \{0, 16, 32, 128, 256\} \)
    Typical range of values: \( 0 \leq \text{Column} \leq 511 \) (lin)
    Minimum increment: 1
    Recommended increment: 1

Complexity

Let \( F \) be the area of an input region, \( F1 \) the area of the structuring element 1, and \( F2 \) the area of the structuring element 2. Then the runtime complexity for one object is:

\[
O \left( \sqrt{F} \cdot \left( \sqrt{F1} + \sqrt{F2} \right) \right).
\]

Result

hit_or_miss returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:
• no region:
  set_system('no_object_result',<RegionResult>)
• empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

```c
minkowski_add1 ( Region,
    StructElement : RegionMinkAdd : Iterations : )
```

Perform a Minkowski addition on a region.

minkowski_add1 dilates the input regions with a structuring element. By applying minkowski_add1 to a region, its boundary gets smoothed. In the process, the area of the region is enlarged. Furthermore, disconnected regions may be merged. Such regions, however, remain logically distinct region. The Minkowski addition is a set-theoretic region operation. It is based on translations and union operations.

Let \( M \) (StructElement) and \( R \) (Region) be two regions, where \( M \) is the structuring element and \( R \) is the region to be processed. Furthermore, let \( m \) be a point in \( M \). Then the displacement vector \( \vec{v}_m = (dx, dy) \) is defined as the difference of the center of gravity of \( M \) and the vector \( \vec{m} \). Let \( t_{\vec{v}_m}(R) \) denote the translation of a region \( R \) by a vector \( \vec{v} \). Then

\[
minkowski_add1(R, M) := \bigcup_{m \in M} t_{\vec{v}_m}(R)
\]

For each point \( m \) in \( M \) a translation of the region \( R \) with \( M \) is performed. The union of all these translations is the Minkowski addition of \( R \) with \( M \). minkowski_add1 is similar to the operator dilation1, the difference is that in dilation1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of \( M \).

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n-1 \) is used as input for iteration \( n \). From the above definition it follows that an empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

--- Attention ---
A Minkowski addition always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.
Parameters

- **Region** (input_object)  
  Regions to be dilated.
- **StructElement** (input_object)  
  Structuring element.
- **RegionMinkAdd** (output_object)  
  Dilated regions.
- **Iterations** (input_control)  
  Number of iterations.

**Default value:** 1

**Suggested values:** Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}

**Typical range of values:** 1 ≤ Iterations (lin)

**Minimum increment:** 1

**Recommended increment:** 1

Complexity

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})
\]

Result

`minkowski_add1` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

```
minkowski_add2 ( Region, StructElement : RegionMinkAdd : Row, Column, Iterations : )
```

Dilate a region (using a reference point).
minkowski_add2 computes the Minkowski addition of the input regions with a structuring element (StructElement) having the reference point (Row,Column). minkowski_add2 has a similar effect as minkowski_add1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \).

An empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Attention

A Minkowski addition always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.

### Parameters

- **Region** (input_object) .................................................. region(-array) \( \sim \) object
  - Regions to be dilated.
- **StructElement** (input_object) ........................................ region \( \sim \) object
  - Structuring element.
- **RegionMinkAdd** (output_object) ..................................... region(-array) \( \sim \) object
  - Dilated regions.
- **Row** (input_control) .................................................. point.y \( \sim \) integer
  - Row coordinate of the reference point.
  - Typical range of values: \( 1 \leq \text{Row} \leq 511 \) (lin)
  - Minimum increment: 1
  - Recommended increment: 1
- **Column** (input_control) ................................................ point.x \( \sim \) integer
  - Column coordinate of the reference point.
  - Typical range of values: \( 1 \leq \text{Column} \leq 511 \) (lin)
  - Minimum increment: 1
  - Recommended increment: 1
- **Iterations** (input_control) ............................................ integer \( \sim \) integer
  - Number of iterations.
  - Default value: 1
  - Suggested values: \( \text{Iterations} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\} \)
  - Typical range of values: \( 1 \leq \text{Iterations} \) (lin)
  - Minimum increment: 1
  - Recommended increment: 1

### Complexity

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations})
\]

### Result

minkowski_add2 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  - set_system(’no_object_result’,<RegionResult>)
- empty region:
  - set_system(’empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

**Module**
Foundation

```hcon
minkowski_sub1 ( Region, StructElement : RegionMinkSub : Iterations : )
```

Erode a region.

*minkowski_sub1* computes the Minkowski subtraction of the input regions with a structuring element. By applying *minkowski_sub1* to a region, its boundary gets smoothed. In the process, the area of the region is reduced. Furthermore, connected regions may be split. Such regions, however, remain logically one region. The Minkowski subtraction is a set-theoretic region operation. It uses the intersection operation.

Let \( M \) (\( \text{StructElement} \)) and \( R \) (\( \text{Region} \)) be two regions, where \( M \) is the structuring element and \( R \) is the region to be processed. Furthermore, let \( m \) be a point in \( M \). Then the displacement vector \( \vec{v}_m = (dx, dy) \) is defined as the difference of the center of gravity of \( M \) and the vector \( \vec{m} \). Let \( t_{\vec{v}_m}(R) \) denote the translation of a region \( R \) by a vector \( \vec{v} \). Then

\[
minkowski_sub1(R,M) := \bigcap_{m \in M} t_{\vec{v}_m}(R)
\]

For each point \( m \) in \( M \) a translation of the region \( R \) is performed. The intersection of all these translations is the Minkowski subtraction of \( R \) with \( M \). \( minkowski_sub1 \) is similar to the operator *erosion1*, the difference is that in *erosion1* the structuring element is mirrored at the origin. The position of \( \text{StructElement} \) is meaningless, since the displacement vectors are determined with respect to the center of gravity of \( M \).

The parameter \( \text{Iterations} \) determines the number of iterations which are to be performed with the structuring element. The result of iteration \( n - 1 \) is used as input for iteration \( n \). From the above definition it follows that the maximum region is generated in case of an empty structuring element.

Structuring elements (\( \text{StructElement} \)) can be generated with operators such as *gen_circle*, *gen_rectangle1*, *gen_rectangle2*, *gen_ellipse*, *draw_region*, *gen_region_polygon*, *gen_region_points*, etc.

**Parameters**

- **Region** (input_object) ................................................ region(-array) \( \sim \) object
  Regions to be eroded.
- **StructElement** (input_object) ................................................ region \( \sim \) object
  Structuring element.
- **RegionMinkSub** (output_object) ........................................... region(-array) \( \sim \) object
  Eroded regions.
Iterations (input_control) .......................... integer  ~ integer
Number of iterations.

Default value: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Typical range of values: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot \text{Iterations}).$$

minkowski_sub1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  `set_system('no_object_result',<RegionResult>)`
- empty region:
  `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

**Module**

Foundation

minkowski_sub2 ( Region, StructElement : RegionMinkSub : Row,
Column, Iterations : )

Erode a region (using a reference point).

minkowski_sub2 computes the Minkowski subtraction of the input regions with a structuring element (StructElement) having the reference point (Row,Column). minkowski_sub2 has a similar effect as minkowski_sub1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration $n$.

A maximum region is generated in case of an empty structuring element.
Structuring elements (*StructElement*) can be generated with operators such as *gen_circle*, *gen_rectangle1*, *gen_rectangle2*, *gen_ellipse*, *draw_region*, *gen_region_polygon*, *gen_region_points*, etc.

### Parameters

- **Region** (input_object)  
  Regions to be eroded.

- **StructElement** (input_object)  
  Structuring element.

- **RegionMinkSub** (output_object)  
  Eroded regions.

- **Row** (input_control)  
  Row coordinate of the reference point.
  - Default value: 0
  - Suggested values: $Row \in \{0, 10, 16, 32, 64, 100, 128\}$
  - Typical range of values: $0 \leq Row \leq 511$ (lin)
  - Minimum increment: 1
  - Recommended increment: 1

- **Column** (input_control)  
  Column coordinate of the reference point.
  - Default value: 0
  - Suggested values: $Column \in \{0, 10, 16, 32, 64, 100, 128\}$
  - Typical range of values: $0 \leq Column \leq 511$ (lin)
  - Minimum increment: 1
  - Recommended increment: 1

- **Iterations** (input_control)  
  Number of iterations.
  - Default value: 1
  - Suggested values: $Iterations \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}$
  - Typical range of values: $1 \leq Iterations$ (lin)
  - Minimum increment: 1
  - Recommended increment: 1

### Complexity

Let $F_1$ be the area of the input region, and $F_2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F_1} \cdot \sqrt{F_2} \cdot Iterations).$$

### Result

*minkowski_sub2* returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```

- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

### Possible Predecessors

```
threshold, regiongrowing, watersheds, class_ndim_norm, gen_circle, gen_ellipse,
```
opening ( Region, StructElement : RegionOpening : : )

Open a region.
An opening operation is defined as an erosion followed by a Minkowski addition. By applying opening to a region, larger structures remain mostly intact, while small structures like lines or points are eliminated. In contrast, a closing operation results in small gaps being retained or filled up (see closing).

opening serves to eliminate small regions (smaller than StructElement) and to smooth the boundaries of a region. The position of StructElement is meaningless, since an opening operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- **Region** (input_object) region(-array) ↦ object
  Regions to be opened.
- **StructElement** (input_object) region ↦ object
  Structuring element (position-invariant).
- **RegionOpening** (output_object) region(-array) ↦ object
  Opened regions.

Example

* Large regions in an aerial picture (beech trees or meadows):
read_image(Image,'forest_road')
threshold(Image,Light,160,255)
gen_circle(StructElement,100,100,10)
* selecting the large regions
opening(Light,StructElement,Large)

* Selecting of edges with certain orientation:
read_image(Image,'fabrik')
sobel_amp(Image,Sobel,'sum_abs',3)
threshold(Sobel,Edges,10,255)
gen_rectangle2(StructElement,100,100,3.07819,20,1)
opening(Edges,StructElement,Direction)

Complexity

Let \( F_1 \) be the area of the input region, and \( F_2 \) be the area of the structuring element. Then the runtime complexity for one region is:

\[
O(2 \cdot \sqrt{F_1} \cdot \sqrt{F_2}) .
\]

Result

opening returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:
• no region:
  set_system('no_object_result',<RegionResult>)
• empty region:
  set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

---

**Execution Information**

**Module**

---

```plaintext
opening_circle ( Region : RegionOpening : Radius : )
```

Open a region with a circular structuring element.

*opening_circle* is defined as an erosion followed by a Minkowski addition with a circular structuring element (see example). *opening* serves to eliminate small regions (smaller than the circular structuring element) and to smooth the boundaries of a region.

---

**Parameters**

- **Region** (input_object)  
  region(-array)  \(\rightarrow\)  object
  Regions to be opened.

- **RegionOpening** (output_object)  
  region(-array)  \(\rightarrow\)  object
  Opened regions.

- **Radius** (input_control)  
  real  \(\rightarrow\)  real / integer
  Radius of the circular structuring element.

  **Default value:** 3.5

  **Suggested values:** \(\text{Radius} \in \{1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5\}\)

  **Typical range of values:** \(0.5 \leq \text{Radius} \leq 511.5\) (lin)

  **Minimum increment:** 1.0

  **Recommended increment:** 1.0

---

**Example**

* Large regions in an aerial picture (beech trees or meadows):*
  read_image (Image, 'forest_road')
  threshold (Image, Region, 120, 255)
* Close the small gaps.
  closing_circle (Region, RegionClosing, 3.5)
* Select the large regions.
  opening_circle (RegionClosing, RegionOpening, 19.5)
CHAPTER 20 MORPHOLOGY

Complexity

Let $F_1$ be the area of the input region. Then the runtime complexity for one region is:

$$O(4 \cdot \sqrt{F_1 \cdot \text{Radius}}).$$

Result

`opening_circle` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  ```
  set_system('no_object_result',<RegionResult>)
  ```
- empty region:
  ```
  set_system('empty_region_result',<RegionResult>)
  ```

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Foundation

`opening_rectangle1 ( Region : RegionOpening : Width, Height : )`

Open a region with a rectangular structuring element.

`opening_rectangle1` performs an `erosion_rectangle1` followed by a `dilation_rectangle1` on the input region `Region`. The size of the rectangular structuring element is determined by the parameters `Width` and `Height`. As is the case for all `opening` variants, larger structures are preserved, while small regions like lines or points are eliminated.

Parameters

- **Region** (input_object)  
  Regions to be opened.
- **RegionOpening** (output_object)  
  Opened regions.
- **Width** (input_control)  
  Width of the structuring rectangle.
  Default value: 10
  Suggested values: Width ∈ {1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200}
  Typical range of values: 1 ≤ Width ≤ 511 (lin)
  Minimum increment: 1
  Recommended increment: 1
20.2. REGION

Height (input_control)                          extent.y \sim integer
Height of the structuring rectangle.
Default value: 10
Suggested values: Height \in \{1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200\}
Typical range of values: 1 \leq Height \leq 511 (lin)
Minimum increment: 1
Recommended increment: 1

 Complexity

Let \( F_1 \) be the area of an input region and \( H \) be the height of the rectangle. Then the runtime complexity for one region is:

\[ O(2 \cdot \sqrt{F_1} \cdot \log(H)) \]

 Result

opening_rectangle1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  set_system(‘no_object_result’,<RegionResult>)
- empty region:
  set_system(‘empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

 Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

 Possible Predecessors

threshold, regiongrowing, watersheds, class_ndim_norm

 Possible Successors

reduce_domain, select_shape, area_center, connection

 Alternatives

opening, gen_rectangle1, dilation_rectangle1, erosion_rectangle1

 Module

Foundation

pruning ( Region : RegionPrune : Length : )

Prune the branches of a region.
pruning removes branches from a skeleton (Region) having a length less than Length. All other branches are preserved.

 Parameters

- Region (input_object)                          region(-array) \sim object
  Regions to be processed.
- RegionPrune (output_object)                    region(-array) \sim object
  Result of the pruning operation.
- Length (input_control)                         integer \sim integer
  Length of the branches to be removed.
Default value: 2
Suggested values: Length \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}
Typical range of values: 1 \leq Length \leq 511 (lin)
Minimum increment: 1
Recommended increment: 1
Complexity

Let $F$ be the area of the input region. Then the runtime complexity for one region is

$$O(\text{Length} \cdot 3 \cdot \sqrt{F})$$.

Result

pruning returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region:
  
  ```
  set_system(‘no_object_result’,<RegionResult>)
  ```

- empty region:
  
  ```
  set_system(‘empty_region_result’,<RegionResult>)
  ```

Otherwise, an exception is raised.

Module

Foundation

```python
top_hat ( Region, StructElement : RegionTopHat : : )
```

Compute the top hat of regions.

top_hat computes the **opening** of Region with StructElement. The difference between the original region and the result of the opening is called the top hat. In contrast to opening, which splits regions under certain circumstances, top_hat computes the regions removed by such a splitting.

The position of StructElement is meaningless, since an opening operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

- **Region** (input_object) ................................................. region(-array) $\rightarrow$ object
  Regions to be processed.
- **StructElement** (input_object) .............................................. region $\rightarrow$ object
  Structuring element (position independent).
- **RegionTopHat** (output_object) .......................................... region(-array) $\rightarrow$ object
  Result of the top hat operator.

Result

top_hat returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:
• no region:
  set_system(‘no_object_result’,<RegionResult>)
• empty region:
  set_system(‘empty_region_result’,<RegionResult>)

Otherwise, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Chapter 21

OCR

21.1 Convolutional Neural Networks

\texttt{clear\_ocr\_class\_cnn ( : : OCRHandle : )}

Clear an CNN-based OCR classifier.

\texttt{clear\_ocr\_class\_cnn} clears the OCR classifier given by \texttt{OCRHandle} that was read with \texttt{read\_ocr\_class\_cnn} and frees all memory required for the classifier. After calling \texttt{clear\_ocr\_class\_cnn}, the classifier can no longer be used. The handle \texttt{OCRHandle} becomes invalid.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{OCRHandle} (input_control) \hspace{1cm} \texttt{ocr\_cnn(-array) \sim handle}
    Handle of the OCR classifier.
\end{itemize}

\textbf{Result}

If \texttt{OCRHandle} is valid, the operator \texttt{clear\_ocr\_class\_cnn} returns the value 2 (H\_MSG\_TRUE). If necessary, an exception is raised.

\textbf{Execution Information}

\begin{itemize}
  \item Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  \item Multithreading scope: global (may be called from any thread).
  \item Processed without parallelization.
\end{itemize}

This operator modifies the state of the following input parameter:

\begin{itemize}
  \item \texttt{OCRHandle}
\end{itemize}

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

\textbf{Possible Predecessors}

\begin{itemize}
  \item \texttt{do\_ocr\_single\_class\_cnn, do\_ocr\_multi\_class\_cnn, do\_ocr\_word\_cnn}
\end{itemize}

\textbf{See also}

\begin{itemize}
  \item \texttt{read\_ocr\_class\_cnn}
\end{itemize}

\textbf{Module}

OCR/OCV

\texttt{deserialize\_ocr\_class\_cnn ( : : SerializedItemHandle : OCRHandle )}

Deserializes a serialized CNN-based OCR classifier.
deserialize_ocr_class_cnn deserializes a CNN-based OCR classifier, that was serialized by serialize_ocr_class_cnn (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

Parameters

- **SerializedItemHandle** (input_control) serialized_item ~ handle
  Handle of the serialized item.
- **OCRHandle** (output_control) ocr_cnn ~ handle
  Handle of the OCR classifier.

Result

If the parameters are valid, the operator deserialize_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_ocr_class_cnn

Possible Successors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn

Module

OCR/OCV

**do_ocr_multi_class_cnn** ( Character, Image : : OCRHandle : Class, Confidence )

Classify multiple characters with an CNN-based OCR classifier.

do_ocr_multi_class_cnn computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence.

In contrast to do_ocr_single_class_cnn, do_ocr_multi_class_cnn can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_cnn to classify single characters. However, do_ocr_multi_class_cnn can only return the best class of each character. Because the confidences can be interpreted as probabilities, it is easier to check whether a character has been classified with too much uncertainty. This is usually not a disadvantage, except in cases where the classes overlap so much that in many cases the second best class must be examined to be able to decide the class of the character. In these cases, do_ocr_single_class_cnn should be used.

A string of the number ’\032’ (alternatively displayed as ’\0x1A’) in Class signifies that the region has been classified as rejection class.

Parameters

- **Character** (input_object) region(-array) ~ object
  Characters to be recognized.
- **Image** (input_object) singlechannelimage ~ object : byte / uint2
  Gray values of the characters.
- **OCRHandle** (input_control) ocr_cnn ~ handle
  Handle of the OCR classifier.
- **Class** (output_control) string(-array) ~ string
  Result of classifying the characters with the CNN.

Number of elements: Class == Character
21.1. CONVOLUTIONAL NEURAL NETWORKS

Confidence (output_control) .................................................. real(-array) \( \sim \) real
Confidence of the class of the characters.

Number of elements: Confidence == Character

Result

If the parameters are valid, the operator do_ocr_multi_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

Possible Predecessors

read_ocr_class_cnn

Alternatives

do_ocr_word_cnn, do_ocr_single_class_cnn

Module

OCR/OCV

Classify a single character with an CNN-based OCR classifier.

do_ocr_single_class_cnn computes the best classification for the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the best Num classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Because multiple classes may be returned by do_ocr_single_class_cnn, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_cnn must be used.

In most cases, do_ocr_multi_class_cnn should be preferred over do_ocr_single_class_cnn, since do_ocr_multi_class_cnn is typically faster than a loop with do_ocr_single_class_cnn. Furthermore, the resulting confidences can be interpreted as probabilities. They indicate the uncertainty of a character’s classification result. The operator do_ocr_single_class_cnn has to be used if the nth-best class has to be examined explicitly for n greater than one.

A string of the number ‘\032’ (alternatively displayed as ‘\0r1A’) in Class signifies that the region has been classified as rejection class.

Parameters

• Character (input_object) ............................................. region \( \sim \) object
 Character to be recognized.

• Image (input_object) ................................................ singlechannelimage \( \sim \) object : byte / uint2
 Gray values of the character.

• OCRHandle (input_control) ................................. ocr_cnn \( \sim \) handle
Handle of the OCR classifier.

• Num (input_control) .............................................. integer-array \( \sim \) integer
Number of best classes to determine.

Default value: 1
Suggested values: Num \( \in \) \{1, 2, 3, 4, 5\}

• Class (output_control) ............................................ string(-array) \( \sim \) string
Result of classifying the character with the CNN.

• Confidence (output_control) .................................... real(-array) \( \sim \) real
Confidence(s) of the class(es) of the character.
Example

read_image(Image, 'bottle2')
OffsetRow := 100
OffsetCol := 108
read_ocr_class_cnn('Universal_0-9_NoRej.occ', OCRHandle)
* Select each digit and use do_ocr_single_class_cnn to apply OCR
gen_rectangle1(ROI_Date, OffsetRow, OffsetCol, OffsetRow, OffsetCol)
for I := 1 to 6 by 1
  Offset := I % 2 * 10
  smallest_rectangle1(ROI_Date, Row1, Col1, Row2, Col2)
  gen_rectangle1(ROI_Date, OffsetRow, Offset + Col2, OffsetRow + 42, 
                Col2 + Offset + 31)
  do_ocr_single_class_cnn(ROI_Date, Image, OCRHandle, 1, Class, Confidence)
endfor

Result
If the parameters are valid, the operator do_ocr_single_class_cnn returns the value 2 (H_MSG_TRUE).
If necessary, an exception is raised.

Execution Information

* Multithreading type: reentrant (runs in parallel with non-exclusive operators).
* Multithreading scope: global (may be called from any thread).
* Processed without parallelization.

Alternatives

do_ocr_multi_class_cnn

Module

OCR/OCV

**do_ocr_word_cnn** ( Character, Image : : OCRHandle, Expression,
NumAlternatives, NumCorrections : Class, Confidence, Word,
Score )

Classify a related group of characters with an CNN-based OCR classifier.

do_ocr_word_cnn works like do_ocr_multi_class_cnn insofar as it computes the best class for each of
the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle,
and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence.

In contrast to do_ocr_multi_class_cnn, do_ocr_word_cnn treats the group of characters as an entity
which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed
classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or
import_lexicon, or by specifying the name of the lexicon in angular brackets as in '<mylexicon>'. If the Expression
is of any other form, it is interpreted as a regular expression with the same syntax as specified for
tuple_regexp_match. Note that you will usually want to use an expression of the form '^...$' when using
variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to
tuple_regexp_match, do_ocr_word_cnn does not support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_cnn
attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives
used are identical to those returned by do_ocr_single_class_cnn for a single character. It does so by testing
all possible corrections for which the classification result is changed for at most NumCorrections character
regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

\[
\text{Score} = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\begin{align*}
\text{PenaltyCorrections} &= \alpha \times \text{num_corr} \\
\text{PenaltyAlternatives} &= \alpha \times \beta \times \text{num_alt}
\end{align*}
\]

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

\[
\begin{align*}
\alpha &= \frac{1}{\text{NumCorrections} + 1} \\
\beta &= \frac{1}{\text{NumCorrections} \times (\text{NumAlternatives} - 1) + 2}
\end{align*}
\]

Note that this is a combinatorial score which does not reflect the original Confidence of the best Class.

A string of the number '032' (alternatively displayed as '0x1A') in Class signifies that the region has been classified as rejection class.

--------- Parameters ---------

- **Character** (input_object) ... region(-array) \( \sim \) object
  Characters to be recognized.

- **Image** (input_object) ... singlechannelimage \( \sim \) object : byte / uint2
  Gray values of the characters.

- **OCRHandle** (input_control) ... ocr_cnn \( \sim \) handle
  Handle of the OCR classifier.

- **Expression** (input_control) ... string \( \sim \) string
  Expression describing the allowed word structure.

- **NumAlternatives** (input_control) ... integer \( \sim \) integer
  Number of classes per character considered for the internal word correction.
  **Default value:** 3
  **Suggested values:** NumAlternatives \( \in \) \{3, 4, 5\}
  **Typical range of values:** 1 \( \leq \) NumAlternatives

- **NumCorrections** (input_control) ... integer \( \sim \) integer
  Maximum number of corrected characters.
  **Default value:** 2
  **Suggested values:** NumCorrections \( \in \) \{1, 2, 3, 4, 5\}
  **Typical range of values:** 0 \( \leq \) NumCorrections

- **Class** (output_control) ... string(-array) \( \sim \) string
  Result of classifying the characters with the CNN.
  **Number of elements:** Class == Character

- **Confidence** (output_control) ... real(-array) \( \sim \) real
  Confidence of the class of the characters.
  **Number of elements:** Confidence == Character

- **Word** (output_control) ... string \( \sim \) string
  Word text after classification and correction.
The complexity of checking all possible corrections is of magnitude \( O((n \times a)^{\min(c,n)}) \), where \( a \) is the number of alternatives, \( n \) is the number of character regions, and \( c \) is the number of allowed corrections. However, to guard against a near-infinite loop in case of large \( n \), \( c \) is internally clipped to 5, 3, or 1 if \( a \times n \geq 30 \), 60, or 90, respectively.

If the parameters are valid, the operator do_ocr_word_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

- read_ocr_class_cnn

### Alternatives

- do_ocr_multi_class_cnn

### Module

OCR/OCV

### get_params_ocr_class_cnn

```cpp
get_params_ocr_class_cnn ( : : OCRHandle, GenParamName : GenParamValue )
```

Return the parameters of a CNN-based OCR classifier.

get_params_ocr_class_cnn returns the parameters GenParamName of an OCR classifier OCRHandle in GenParamValue. This is particularly useful if the classifier was read with read_ocr_class_cnn. The output of get_params_ocr_class_cnn can, for example, be used to check whether a character to be read is contained in the classifier.

Possible values for GenParamName are:

- 'characters': Returns a list of all trained symbols which may be recognized by the CNN-based OCR classifier.

  Note that if 'characters' is specified then no other generic parameter is allowed. Otherwise an exception is thrown.

### Parameters

- **OCRHandle** (input_control) .......................... ocr_cnn \( \rightarrow \) handle
  Handle of the OCR classifier.

- **GenParamName** (input_control) ...................... string(-array) \( \rightarrow \) string
  A tuple of generic parameter names.

  **Default value:** 'characters'

  **List of values:** GenParamName \( \in \) ['characters']

- **GenParamValue** (output_control) .................... string(-array) \( \rightarrow \) integer / string
  A tuple of generic parameter values.

### Result

If the parameters are valid, the operator get_params_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
21.1. CONVOLUTIONAL NEURAL NETWORKS

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

query_params_ocr_class_cnn ( : : OCRHandle : GenParamName )

Get the names of the parameters that can be used in get_params_ocr_class_cnn for a given CNN-based OCR classifier.

The operator query_params_ocr_class_cnn returns the parameter names that can be used to query all parameters for a given CNN-based OCR classifier. The resulting parameter names can be used as input parameter when calling get_params_ocr_class_cnn.

Parameters

- **OCRHandle** (input_control) .................. ocr_cnn ~ handle
  Handle of OCR classifier.
- **GenParamName** (output_control) ................. string(-array) ~ string
  Names of the generic parameters.

Result

The operator query_params_ocr_class_cnn returns the value 2 (H_MSG_TRUE) if the given handle for the OCR classifier is correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_ocr_class_cnn ( : : FileName : OCRHandle )

Read an CNN-based OCR classifier from a file.

read_ocr_class_cnn reads a pretrained OCR classifier based on a convolutional neural network (CNN).

The CNN-based OCR classifier is read with read_ocr_class_cnn and subsequently used for classification with either do_ocr_single_class_cnn, do_ocr_multi_class_cnn, or do_ocr_word_cnn.

HALCON provides a number of pretrained OCR classifiers (see "Solution Guide I", chapter 'OCR', section 'Pretrained OCR Fonts'). These pretrained OCR classifiers make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Note that the pretrained OCR classifiers were trained with symbols that are printed dark on light.
Parameters

- **FileName** (input_control) ......................... filename.read \(\sim\) string
  File name.
  Default value: 'Universal_Rej.occ'
- **OCRHandle** (output_control) .................. ocr_cnn \(\sim\) handle
  Handle of the OCR classifier.

Result

If the parameters are valid, the operator `read_ocr_class_cnn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

- `do_ocr_single_class_cnn`, `do_ocr_multi_class_cnn`, `do_ocr_word_cnn`
- `get_params_ocr_class_cnn`

See also

Module

**serialize_ocr_class_cnn** ( : : OCRHandle : SerializedItemHandle )

Serialize a CNN-based OCR classifier

`serialize_ocr_class_cnn` serializes a CNN-based OCR classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The OCR classifier is defined by the handle `OCRHandle`. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr_class_cnn`.

Parameters

- **OCRHandle** (input_control) ......................... ocr_cnn \(\sim\) handle
  Handle of the OCR classifier.
- **SerializedItemHandle** (output_control) .................... serialized_item \(\sim\) handle
  Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr_class_cnn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
21.2 Deep OCR

**Possible Successors**
clear_ocr_class_cnn, fwrite_serialized_item, send_serialized_item, deserialize_ocr_class_cnn

Module

21.2 Deep OCR

|apply_deep_ocr ( Image : : DeepOcrHandle, Mode : DeepOcrResult )|

Apply a Deep OCR model on a set of images for inference.

*apply_deep_ocr* applies the Deep OCR model given by *DeepOcrHandle* on the tuple of input images *Image*. The operator returns *DeepOcrResult*, a tuple with a result dictionary for every input image.

The operator *apply_deep_ocr* poses requirements on the input *Image*:

- Image type: byte or real.
- Number of channels: Depending on the *Mode*
  - `'auto'`: 1 or 3
  - `'detection'`: 1 or 3
  - `'recognition'`: 1

Further, the operator *apply_deep_ocr* will preprocess the given *Image* to match the model specifications. This means, the input image will be converted to type real. Byte images will also be normalized. Further, for *Mode* = *'auto'* or *'detection'* the input image *Image* is padded to the model input dimensions and, in case it has only one channel, converted into a three-channel image.

The parameter *Mode* specifies a mode and with it, which component is executed. Supported values:

- `'auto'` (A): Perform both parts, detection of the word and its recognition.
- `'detection'` (DET): Perform only the detection part. Hence, the model will merely localize the word regions within the image.
- `'recognition'` (REC): Perform only the recognition part. Hence, the model requires that the image contains solely a tight crop of the word.

Note, the model must have been created with the desired component, see *create_deep_ocr*.

The output dictionary *DeepOcrResult* can have entries according to the applied *Mode* (marked by its abbreviation):

- **image** (A, DET, REC): Preprocessed image.
- **score_maps** (A, DET): Scores given as image with four channels:
  - Character score: Score for the character detection.
  - Link score: Score for the connection of detected character centers to a connected word.
  - Orientation 1: Sine component of the predicted word orientation.
  - Orientation 2: Cosine component of the predicted word orientation.
- **words** (A, DET): Dictionary containing the following entries. Thereby, the entries are tuples with a value for every found word.
  - **word** (A): Recognized word.
  - **word_image** (A): Preprocessed image part containing the word.
  - **row** (A, DET): Localized word: Center point, row coordinate.
  - **col** (A, DET): Localized word: Center point, column coordinate.
  - **phi** (A, DET): Localized word: Angle phi.
  - **length1** (A, DET): Localized word: Half length of edge 1.
  - **length2** (A, DET): Localized word: Half length of edge 2.
- `line_index` (A, DET): Line index of localized word if 'detection_sort_by_line' set to 'true'.

The word localization is given by the parameters of an oriented rectangle, see `gen_rectangle2` for further information.

**word** (REC): Recognized word.

---

Attention

System requirements: To run this operator on GPU (see `get_deep_ocr_param`), cuDNN and cuBLAS are required. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods". Alternatively, this operator can also be run on CPU.

---

### Parameters

- **Image** (input_object) .................................................. (multichannel-)image(-array) `object : byte / real`
  - Input image.
- **DeepOcrHandle** (input_control) .......................................................... deep_ocr `handle`
  - Handle of the Deep OCR model.
- **Mode** (input_control) .......................................................... string `string`
  - Inference mode.
    - **Default value:** `[]`
    - **List of values:** `Mode ∈ ['auto', 'recognition', 'detection']`
- **DeepOcrResult** (output_control) ........................................... dict(-array) `handle`
  - Tuple of result dictionaries.

---

### Result

If the parameters are valid, the operator `apply_deep_ocr` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

---

### Possible Predecessors

- `get_deep_ocr_param`, `set_deep_ocr_param`, `create_deep_ocr`

OCR/OCV

---

```cpp
create_deep_ocr ( : : GenParamName, GenParamValue : DeepOcrHandle )
```

Create a Deep OCR model.

create_deep_ocr creates a Deep OCR model out of pretrained components and returns its handle in DeepOcrHandle. The handle states all parameters needed to run an inference.

A Deep OCR model usually consists of two components:

- `'detection_model'`: detects words (connected characters) in the image.
- `'recognition_model'`: recognizes the word in the detected image part.

The following options may be set using `GenParamName` and according `GenParamValue`:

- `'mode'`: Specify a mode and with it, which component is executed. Supported values:
  - `'detection'`: Perform only the detection part. Hence, the model will merely localize the word regions within the image.
'recognition': Perform only the recognition part. Hence, the model requires that the image contains solely a tight crop of the word.

'auto': Perform both parts, detection of the words and their recognition.

Default: 'auto'.

The character set, which the model can recognize through its recognition component, can be retrieved using get_deep_ocr_param with 'recognition_alphabet'.

---

Parameters

apply_deep_ocr, get_deep_ocr_param, set_deep_ocr_param, clear_handle

---

Module

OCR/OCV

---

get_deep_ocr_param ( : : DeepOcrHandle,
                     GenParamName : GenParamValue )

Return the parameters of a Deep OCR model.

get_deep_ocr_param returns the parameter values GenParamValue of GenParamName for the Deep OCR model DeepOcrHandle.

Parameters can apply to the whole model or be specific for a given component. The following table gives an overview, which parameters can be set and which ones retrieved as well as for which model part they apply.
The parameters and abbreviations denote the following:

- 's': The parameter can be set using `set_deep_ocr_param`.
- 'g': The parameter can be retrieved using `get_deep_ocr_param`.
- '-': The parameter is not applicable.
- Model: Entire Deep OCR model with all its components.
- Det. comp.: Detection component.
- Recog. comp.: Recognition component.

In the following the parameters are described, sorted according to the part of the model they apply to:

### Entire model:

'device':
Handle of the device on which the model will be executed. To get a tuple of handles of all available potentially Deep-OCR-capable compute devices use `query_available_dl_devices`. Note, the device can be reset for an individual component, in which case only the possibly remaining part of the model (e.g., the remaining component) will be executed on the device of this handle.

Default: Handle of the default device, thus the GPU with index 0 when querying a list using `get_system` with 'cuda_devices'. If no device is available, this is an empty tuple.

### Detection component:

detection_device':
This parameter will set the device on which the detection component of the Deep OCR model is executed. For a further description, see 'device'.

Default: The same value as for 'device'.

detection_image_dimensions':
Tuple containing the image dimensions ('detection_image_width', 'detection_image_height', number of channels) the detection component will process.

Default: [1024, 1024, 3]
'detection_image_height':
   Height of the images the detection component will process. This means, the network will first zoom the input image to this height before processing it. Thus this size can influence the results.
   The model architecture requires that the height is a multiple of two. If this is not the case, the height is rounded up to the nearest integer multiple of two.
   Typical values: 768, 1024, 1280
   Default: 1024

'detection_image_width':
   Width of the images the detection component will process. This means, the network will first zoom the input image to this width before processing it. Thus this size can influence the results.
   The model architecture requires that the width is a multiple of two. If this is not the case, the width is rounded up to the nearest integer multiple of two.
   Typical values: 768, 1024, 1280
   Default: 1024

'detection_min_character_score':
   The parameter 'detection_min_character_score' specifies the lower threshold used for the character score map to estimate the dimensions of the characters. By adjusting the parameter, suggested instances can be split up or neighboring instances can be merged.
   Range: ∈ [0, 1].
   Default: 0.5

'detection_min_link_score':
   The parameter 'detection_min_link_score' defines the minimum link score required between two localized characters to recognize these characters as coherent word.
   Range: ∈ [0, 1].
   Default: 0.3

'detection_min_word_area':
   The parameter 'detection_min_word_area' defines the minimum size that a localized word must have in order to be suggested. This parameter can be used to filter suggestions that are too small.
   Range: ≥ 0.
   Default: 10.

'detection_min_word_score':
   The parameter 'detection_min_word_score' defines the minimum score a localized instance must contain to be suggested as valid word. With this parameter uncertain words can be filtered out.
   Range: ∈ [0, 1].
   Default: 0.7

'detection_model':
   Handle of the Deep OCR model component for word detection.

'detection_orientation':
   This parameter allows to set a predefined orientation angle for the word detection. To revert to default behavior using the internal orientation estimation, 'detection_orientation' is set to 'auto'.
   Range: (-\pi, \pi].
   Default: 'auto'

'detection_sort_by_line':
   The words are sorted line-wise based on the orientation of the localized word instances. If a sorting in row and column direction is preferred, the parameter 'detection_sort_by_line' has to be set to 'false'.
   Default: 'true'

Recognition component:

'recognition_alphabet':
   The character set with which the Deep OCR model has been trained, thus the characters the model can recognize.

'recognition_device':
   This parameter will set the device on which the recognition component of the Deep OCR model is executed. For a further description, see 'device'.
   Default: The same value as for 'device'.

'recognition_image_dimensions':
   Tuple containing the image dimensions ('recognition_image_width', 'recognition_image_height', number of channels) the recognition component will process.
Default: [100, 32, 1]

'recognition_image_height':
  Height of the images the recognition component will process. This means, the network will first zoom
  the input image part to this height before processing it.
  Default: 32

'recognition_image_width':
  Width of the images the recognition component will process. This means, the network will first zoom
  the input image part to this width before processing it.
  Default: 100

'recognition_model':
  Handle of the Deep OCR model component for word recognition.

Parameters

- **DeepOcrHandle** (input_control) .............................................. deep_ocr ~ handle
  Handle of the Deep OCR model.

- **GenParamName** (input_control) .............................................. attribute.name ~ string
  Name of the generic parameter.
  Default value: 'recognition_model'
  List of values: GenParamName ∈ {'detection_device', 'detection_image_dimensions',
  'detection_image_height', 'detection_image_width', 'detection_min_character_score',
  'detection_min_link_score', 'detection_min_word_area', 'detection_min_word_score', 'detection_model',
  'detection_orientation', 'detection_sort_by_line', 'recognition_alphabet', 'recognition_device',
  'recognition_image_dimensions', 'recognition_image_height', 'recognition_image_width',
  'recognition_model'}

- **GenParamValue** (output_control) ......................... attribute.value(-array) ~ integer / handle / string / real
  Value of the generic parameter.

Result

If the parameters are valid, the operator *get_deep_ocr_param* returns the value 2 (H_MSG_TRUE). If neces-

sary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

OCR/OCV

**read_deep_ocr** ( : : FileName : DeepOcrHandle )

Read a Deep OCR model from a file.

The operator *read_deep_ocr* reads a Deep OCR model. Such models have to be in the HALCON format. As a
result, the handle DeepOcrHandle is returned.

The model is loaded from the file FileName. This file is thereby searched in the directory $HALCONROOT/dl/
as well as in the currently used directory. The default HALCON file extension for Deep OCR models is '.hdo'.
Please note that the values of runtime specific parameters are not written to file, see `write_deep_ocr`. As a consequence when reading a model these parameters are initialized with their default value, see `get_deep_ocr_param`.

**Parameters**

- **FileName** (input_control) 
  
  File extension: .hdo

- **DeepOcrHandle** (output_control) 
  
  Handle of the Deep OCR model.

**Result**

If the parameters are valid, the operator `read_deep_ocr` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Successors**

**Module**

OCR/OCV

```haskell
set_deep_ocr_param ( : : DeepOcrHandle, GenParamName, GenParamValue : )
```

Set the parameters of a Deep OCR model.

The possible parameters are listed and described in `get_deep_ocr_param`.

**Attention**

System requirements: To successfully set ‘gpu’ parameters, cuDNN and cuBLAS are required, i.e., to set the parameter `GenParamName 'device'` to a GPU. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

**Parameters**

- **DeepOcrHandle** (input_control) 
  
  Handle of the Deep OCR model.

- **GenParamName** (input_control) 
  
  Name of the generic parameter.

  Default value: 'detection_image_width'

  List of values: GenParamName ∈ {'device', 'detection_device', 'detection_image_height', 'detection_image_width', 'detection_min_character_score', 'detection_min_link_score', 'detection_min_word_area', 'detection_min_word_score', 'detection_orientation', 'detection_sort_by_line', 'recognition_device', 'recognition_image_width'}

- **GenParamValue** (input_control) 
  
  Value of the generic parameter.

  Default value: 1024

  Suggested values: GenParamValue ∈ {0, 10, 50, 100, 200, 512, 768, 1024, 1280, 0.3, 0.4, 0.5, 0.6, 0.7, 'true', 'false', 'auto'}
If the parameters are valid, the operator `set_deep_ocr_param` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

#### clear_ocr_class_knn

| : : OCRHandle : : |

Clear an OCR classifier.

---

HALCON/HDevelop Reference Manual, 2020-11-10
clear_ocr_class_knn clears the OCR classifier given by OCRHandle that was created with create_ocr_class_knn and frees all memory required for the classifier. After calling clear_ocr_class_knn, the classifier can no longer be used. The handle OCRHandle becomes invalid.

---

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OCRHandle</td>
<td>Handle of the OCR classifier.</td>
</tr>
</tbody>
</table>

**Result**

If OCRHandle is valid, the operator clear_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **OCRHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**create_ocr_class_knn**

create_ocr_class_knn ( : : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, GenParamName, GenParamValue : OCRHandle )

Create an OCR classifier using a k-Nearest Neighbor (k-NN) classifier.

create_ocr_class_knn creates an OCR classifier that uses a k-Nearest Neighbor (k-NN). The handle of the k-NN classifier is returned in OCRHandle.

For a description on how a k-NN works, see create_class_knn.

The length of the feature vector of the k-NN is determined from the features that are used for the OCR, which are passed in Features. The features are described below. The number of classes is determined from the names of the characters which are passed in Characters.

Features can contain a tuple of several feature names. Each of these names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., ‘pixel_invar’). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by WidthCharacter and HeightCharacter. The interpolation to be used for the transformation is determined by Interpolation. It has the same meaning as in affine_trans_image. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, Interpolation = ’constant’ should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, large sizes will cause small segmentation errors to have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, which results in characters are zoomed differently than the characters in the training set. In most applications, sizes between 6 × 8 and 10 × 14 should be used.

The parameter Features can contain the following feature names for the classification of the characters.
'default': 'ratio' and 'pixel_invar' are selected.

'pixel:' Gray values of the character ($Width_{Character} \times Height_{Character}$ features).

'pixel_invar:' Gray values of the character with maximum scaling of the gray values ($Width_{Character} \times Height_{Character}$ features).

'pixel_binary:' Region of the character as a binary image zoomed to a size of $Width_{Character} \times Height_{Character}$ ($Width_{Character} \times Height_{Character}$ features).

'gradient_8dir:' Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a $5 \times 5$ grid are extracted from each channel. These samples are used as features (200 features).

'projection_horizontal:' Horizontal projection of the gray values (see gray_projections, $Height_{Character}$ features).

'projection_horizontal_invar:' Maximally scaled horizontal projection of the gray values ($Height_{Character}$ features).

'projection_vertical:' Vertical projection of the gray values (see gray_projections, $Width_{Character}$ features).

'projection_vertical_invar:' Maximally scaled vertical projection of the gray values ($Width_{Character}$ features).

'ratio:' Aspect ratio of the character (see $height_width_{ratio}$, 1 feature).

'anisometry:' Anisometry of the character (see eccentricity, 1 feature).

'width:' Width of the character before scaling the character to the standard size (not scale-invariant, see $height_width_{ratio}$, 1 feature).

'height:' Height of the character before scaling the character to the standard size (not scale-invariant, see $height_width_{ratio}$, 1 feature).

'zoom_factor:' Difference in size between the character and the values $Width_{Character}$ and $Height_{Character}$ (not scale-invariant, 1 feature).

'foreground:' Fraction of pixels in the foreground (1 feature).

'foreground_grid_9:' Fraction of pixels in the foreground in a $3 \times 3$ grid within the smallest enclosing rectangle of the character (9 features).

'foreground_grid_16:' Fraction of pixels in the foreground in a $4 \times 4$ grid within the smallest enclosing rectangle of the character (16 features).

'compactness:' Compactness of the character (see compactness, 1 feature).

'convexity:' Convexity of the character (see convexity, 1 feature).

'moments_region_2nd_invar:' Normalized 2nd moments of the character (see moments_region_2nd_invar, 3 features).

'moments_region_2nd_rel_invar:' Normalized 2nd relative moments of the character (see moments_region_2nd_rel_invar, 2 features).

'moments_region_3rd_invar:' Normalized 3rd moments of the character (see moments_region_3rd_invar, 4 features).

'moments_central:' Normalized central moments of the character (see moments_region_central, 4 features).

'moments_gray_plane:' Normalized gray value moments and the angle of the gray value plane (see moments_gray_plane, 4 features).

'phi:' Sinus and cosinus of the orientation (angle) of the character (see elliptic_axis, 2 feature).

'num_connect:' Number of connected components (see connect_and_holes, 1 feature).

'num_holes:' Number of holes (see connect_and_holes, 1 feature).

'cooc:' Values of the binary cooccurrence matrix (see gen_cooc_matrix, 8 features).

'numRuns:' Number of runs in the region normalized by the height (1 feature).

'chord_histo:' Frequency of the runs per row (not scale-invariant, $Height_{Character}$ features).
After the classifier has been created, it is trained using `trainf_ocr_class_knn`. After this, the classifier can be saved using `write_ocr_class_knn`. Alternatively, the classifier can be used immediately after training to classify characters using `do_ocr_single_class_knn` or `do_ocr_multi_class_knn`.

A comparison of the k-NN and the support vector machine (SVM) (see `create_ocr_class_svm`) typically shows that SVMs are generally slower at training, especially for huge training sets, but achieve slightly better recognition rates than k-NNs. Please note that this guideline assumes optimal tuning of the parameters of the SVM.

```plaintext
Parameters

- **WidthCharacter** (input_control) .................................................. integer ➔ integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 8
  Suggested values: `WidthCharacter` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
  Typical range of values: `4 ≤ WidthCharacter ≤ 20`

- **HeightCharacter** (input_control) .................................................. integer ➔ integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 10
  Suggested values: `HeightCharacter` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
  Typical range of values: `4 ≤ HeightCharacter ≤ 20`

- **Interpolation** (input_control) .................................................. string ➔ string
  Interpolation mode for the zooming of the characters.
  Default value: 'constant'
  List of values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

- **Features** (input_control) .................................................. string(-array) ➔ string
  Features to be used for classification.
  Default value: 'default'
  List of values: `Features` ∈ {'default', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir',
  'projection_horizontal', 'projection_horizontal_invar', 'projection_vertical', 'projection_vertical_invar',
  'ratio', 'anisometry', 'width', 'height', 'zoom_factor', 'foreground', 'foreground_grid_9',
  'foreground_grid_16', 'compactness', 'convexity', 'moments_region_2nd_invar',
  'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'moments_gray_plane',
  'phi', 'num_connect', 'num_holes', 'cooc', 'num_runs', 'chord_histo'}

- **Characters** (input_control) .................................................. string-array ➔ string
  All characters of the character set to be read.
  Default value: ['0', '1', '2', '3', '4', '5', '6', '7', '8', '9']

- **GenParamName** (input_control) .................................................. string-array ➔ string
  This parameter is not yet supported.
  Default value: []
  List of values: `GenParamName` ∈ []

- **GenParamValue** (input_control) .................................................. number-array ➔ integer / string
  This parameter is not yet supported.
  Default value: []
  List of values: `GenParamValue` ∈ []

- **OCRHandle** (output_control) .................................................. ocr_knn ➔ handle
  Handle of the k-NN classifier.
```

---

**Example**

```plaintext
read_image (Image, 'letters')
  * Segment the image.
  binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
  dilation_circle (Region, RegionDilation, 3.5)
  connection (RegionDilation, ConnectedRegions)
  intersection (ConnectedRegions, Region, RegionIntersection)
  sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
  * Generate the training file.
  count_obj (Characters, Number)
  Classes := []
```

**HALCON 20.11.0.0**
for J := 0 to 25 by 1
    Classes := [Classes, gen_tuple_const(20, chr(ord('a')+J))]
endfor
Classes := [Classes, gen_tuple_const(20, '.')]
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_knn (8, 10, 'constant', 'default', CharacterNames, \[
    [], [], OCRHandle\]
trainf_ocr_class_knn (OCRHandle, 'letters.trf', [\], [[]])
* Re-classify the characters in the image.
do_ocr_multi_class_knn (Characters, Image, OCRHandle, Class, Confidence)

If the parameters are valid, the operator create_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

deserialize_ocr_class_knn ( : : SerializedItemHandle : OCRHandle )

Deserialize a serialized k-NN-based OCR classifier.

deserialize_ocr_class_knn deserializes a k-NN-based OCR classifier, that was serialized by serialize_ocr_class_knn (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

Parameters

- **SerializedItemHandle** (input_control) .......................... serialized_item => handle
  Handle of the serialized item.
- **OCRHandle** (output_control) .............................. ocr_knn => handle
  Handle of the OCR classifier.

Result

If the parameters are valid, the operator deserialize_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
21.3. K-NEAREST NEIGHBORS

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

\[ \text{do_ocr_multi_class_knn} \ ( \text{Character}, \ \text{Image} : : \ \text{OCRHandle} : \ \text{Class}, \ \text{Confidence} ) \]

Classify multiple characters with an k-NN classifier.

do_ocr_multi_class_knn computes the best class for each of the characters given by the regions Character and the gray values Image with the k-NN classifier OCRHandle and returns the classes in Class and the corresponding confidence of the classes in Confidence. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification of the single characters. In contrast to do_ocr_single_class_knn, do_ocr_multi_class_knn can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_knn to classify single characters. However, do_ocr_multi_class_knn can only return the best class of each character.

Before calling do_ocr_multi_class_knn, the classifier must be trained with trainf_ocr_class_knn.

Parameters

- **Character**: (input_object) region(-array) \( \sim \) object
  - Characters to be recognized.
- **Image**: (input_object) singlechannelimage \( \sim \) object: byte / uint2
  - Gray values of the characters.
- **OCRHandle**: (input_control) ocr_knn \( \sim \) handle
  - Handle of the k-NN classifier.
- **Class**: (output_control) string(-array) \( \sim \) string
  - Result of classifying the characters with the k-NN.
  - **Number of elements**: Class == Character
- **Confidence**: (output_control) real(-array) \( \sim \) real
  - Confidence of the class of the characters.
  - **Number of elements**: Confidence == Character

Result

If the parameters are valid, the operator do_ocr_multi_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

- trainf_ocr_class_knn
- read_ocr_class_knn

Alternatives

- do_ocr_single_class_knn
Classify a single character with an OCR classifier.

do_ocr_single_class_knn uses the OCR-k-NN classifier OCRHandle to determine the best training samples for the features of the character given by the region Character and the gray values Image and returns their classes in Class and the corresponding confidences in Confidence. If the first NumNeighbors training vectors have different classes, maximally NumClasses classes are returned sorted by frequency and weighted distance. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification. The confidence can be only computed robustly if NumNeighbors is large enough.

Because multiple classes may be returned by do_ocr_single_class_knn, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_knn must be used. Before calling do_ocr_single_class_knn, the classifier must be trained with trainf_ocr_class_knn or select_feature_set_trainf_knn. If all NumNeighbors neighbors are of the same class, only one class is returned.

### Parameters

- **Character** (input_object) .................................................. region ~ object
  Character to be recognized.
- **Image** (input_object) ................................................. singlechannelimage ~ object : byte / uint2
  Gray values of the character.
- **OCRHandle** (input_control) ............................................ ocr_knn ~ handle
  Handle of the k-NN classifier.
- **NumClasses** (input_control) ........................................ integer-array ~ integer
  Number of maximal classes to determine.
  Default value: 1
  Suggested values: NumClasses ∈ {1, 2, 3, 4, 5}
- **NumNeighbors** (input_control) ....................................... integer-array ~ integer
  Number of neighbors to consider.
  Default value: 1
  Suggested values: NumNeighbors ∈ {1, 2, 3, 4, 5}
- **Class** (output_control) .............................................. string(-array) ~ string
  Results of classifying the character with the k-NN.
- **Confidence** (output_control) ......................................... real(-array) ~ real
  Confidence(s) of the class(es) of the character.

### Result

If the parameters are valid, the operator do_ocr_single_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

trainf_ocr_class_knn, read_ocr_class_knn

#### do_ocr_word_knn

*Classify a related group of characters with an OCR classifier.*

The function `do_ocr_word_knn` works similarly to `do_ocr_multi_class_knn` insofar as it computes the best class for each of the characters given by the regions `Character` and the gray values `Image` with the OCR classifier `OCRHandle`, and returns the classes in `Class` and the corresponding confidences of the classes in `Confidence`. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification of the single characters.

In contrast to `do_ocr_multi_class_knn`, `do_ocr_word_knn` treats the group of characters as an entity which yields a `Word` by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an `Expression` describing the expected word.

The `Expression` may restrict the word to belong to a predefined lexicon created using `create_lexicon` or `import_lexicon`, by specifying the name of the lexicon in angular brackets as in `'<mylexicon>'`. If the `Expression` is of any other form, it is interpreted as a regular expression with the same syntax as specified for `tuple_regexp_match`. Note that you will usually want to use an expression of the form `'^...$'` when using variable quantifiers like `'*'`, to ensure that the entire word is used in the expression. Also note that in contrast to `tuple_regexp_match`, `do_ocr_word_knn` does not support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the `Expression`, `do_ocr_word_knn` attempts to correct it by considering the `NumAlternatives` best classes for each character. The alternatives used are identical to those returned by `do_ocr_single_class_knn` for a single character. It does so by testing all possible corrections for which the classification result is changed for at most `NumCorrections` character regions. Note that `NumAlternatives` and `NumCorrections` affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the `Expression` is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than `NumCorrections` edit operations for the correction (see `suggest_lexicon`).

The resulting word is graded by a `Score` between 0.0 (no correction found) and 1.0 (original word correct). The `Score` is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the `Expression`:

\[
\text{Score} = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\text{PenaltyCorrections} = \alpha \times \text{num_corr}
\]

\[
\text{PenaltyAlternatives} = \alpha \times \beta \times \text{num_alt}
\]

with `num_corr` being the actual number of applied corrections and `num_alt` the total number of discarded alternatives.

\[
\alpha = \frac{1}{\text{NumCorrections} + 1}
\]

\[
\beta = \frac{1}{\text{NumCorrections} \times (\text{NumAlternatives} - 1) + 2}
\]

Note that this is a combinatorial score which does **not** reflect the original `Confidence` of the best `Class`. 
Parameters

- **Character** (input_object) .......................... region(-array) ~ object
  Characters to be recognized.
- **Image** (input_object) ............................. singlechannelimage ~ object : byte / uint2
  Gray values of the characters.
- **OCRHandle** (input_control) ........................ ocr_knn ~ handle
  Handle of the OCR classifier.
- **Expression** (input_control) ........................ string ~ string
  Expression describing the allowed word structure.
- **NumAlternatives** (input_control) ................ integer ~ integer
  Number of classes per character considered for the internal word correction.
  Default value: 3
  Suggested values: NumAlternatives ∈ {3, 4, 5}
  Typical range of values: 1 ≤ NumAlternatives ≤ 5
- **NumCorrections** (input_control) ................ integer ~ integer
  Maximum number of corrected characters.
  Default value: 2
  Suggested values: NumCorrections ∈ {1, 2, 3, 4, 5}
  Typical range of values: 0 ≤ NumCorrections ≤ 5
- **Class** (output_control) .......................... string(-array) ~ string
  Result of classifying the characters with the k-NN.
  Number of elements: Class == Character
- **Confidence** (output_control) ...................... real(-array) ~ real
  Confidence of the class of the characters.
  Number of elements: Confidence == Character
- **Word** (output_control) .......................... string ~ string
  Word text after classification and correction.
- **Score** (output_control) .......................... real ~ real
  Measure of similarity between corrected word and uncorrected classification results.

Complexity

The complexity of checking all possible corrections is of magnitude $O((n \times a)^{\min(c,n)})$, where $a$ is the number of alternatives, $n$ is the number of character regions, and $c$ is the number of allowed corrections. However, to guard against a near-infinite loop in case of large $n$, $c$ is internally clipped to 5, 3, or 1 if $a \times n \geq 30, 60,$ or $90$, respectively.

Result

If the parameters are valid, the operator `do_ocr_word_knn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV
Compute the features of a character.

get_features_ocr_class_knn computes the features of the character given by Character with the k-NN classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_knn and do_ocr_multi_class_knn, the character is passed as a single image object. Hence, before calling get_features_ocr_class_knn, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_knn for the classifier should be applied (Transform = 'true') or whether the untransformed features should be returned (Transform = 'false'). get_features_ocr_class_knn can be used to inspect the features that are used for the classification.

### Parameters

- **Character** (input_object) singlechannelimage object : byte / uint2
  Input character.
- **OCRHandle** (input_control) ocr_knn handle
  Handle of the k-NN classifier.
- **Transform** (input_control) string
  Should the feature vector be transformed with the preprocessing?
  Default value: 'true'
  List of values: Transform ∈ ['true', 'false']
- **Features** (output_control) real-array real
  Feature vector of the character.

### Result

If the parameters are valid, the operator get_features_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

### Possible Predecessors

trainf_ocr_class_knn

create_ocr_class_knn

Module

OCR/OCV

Return the parameters of an OCR classifier.

get_params_ocr_class_knn returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_knn. This is particularly useful if the classifier was read with read_ocr_class_knn. The output of get_params_ocr_class_knn can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_knn and trainf_ocr_class_knn.
### Parameters

- **OCRHandle** (input_control)  
  Handle of the OCR classifier.
- **WidthCharacter** (output_control)  
  Width of the rectangle to which the gray values of the segmented character are zoomed.
- **HeightCharacter** (output_control)  
  Height of the rectangle to which the gray values of the segmented character are zoomed.
- **Interpolation** (output_control)  
  Interpolation mode for the zooming of the characters.
- **Features** (output_control)  
  Features to be used for classification.
- **Characters** (output_control)  
  Characters of the character set to be read.
- **Preprocessing** (output_control)  
  Type of preprocessing used to transform the feature vectors.
- **NumTrees** (output_control)  
  Number of different trees used during the classification.

If the parameters are valid, the operator **get_params_ocr_class_knn** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**read_ocr_class_knn**  
( : : FileName : OCRHandle )

Read an OCR classifier from a file.

**read_ocr_class_knn** reads an OCR classifier that has been stored with **write_ocr_class_knn**.

### Parameters

- **FileName** (input_control)  
  File name.
  File extension: .onc, .okc, .fnt
- **OCRHandle** (output_control)  
  Handle of the OCR classifier.

If the parameters are valid, the operator **read_ocr_class_knn** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
21.3. K-NEAREST NEIGHBORS

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

OCR/OCV

```
select_feature_set_trainf_knn ( : : TrainingFile, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score )
```

Select an optimal combination of features to classify OCR data.

select_feature_set_trainf_knn selects an optimal combination of features, to classify the data given in the training file TrainingFile with a k-Nearest Neighbor classifier, for details see create_ocr_class_knn.

Possible features are all OCR features listed and explained in create_ocr_class_knn. All candidates which should be tested can be specified in FeatureList. A subset of these features is returned as selected features in FeatureSet.

select_feature_set_trainf_knn is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator select_feature_set_knn.

The selection method SelectionMethod is either a greedy search 'greedy' (iteratively add the feature with highest gain) or the dynamically oscillating search 'greedy_oscillating' (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method 'greedy' is generally preferable, since it is faster. Only in cases when a large training set is available the method 'greedy_oscillating' might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.

The k-NN classifier can be parametrized using the following values in GenParamName and GenParamValue:

'num_neighbors': The number of minimally evaluated nodes, increase this value for high dimensional data.

  Possible values: '1', '2', '5', '10'
  Default value: '1'

'num_trees': Number of search trees in the k-NN classifier

  Possible values: '1', '4', '10'
  Default Value: '4'

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_knn may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.
Parameters

- **TrainingFile** (input_control) ........................................ filename.read(-array) \(\sim\) string
  - Names of the training files.
  - Default value: "
  - File extension: .trf, .otr

- **FeatureList** (input_control) ........................................ string(-array) \(\sim\) string
  - List of features that should be considered for selection.
  - Default value:

- **SelectionMethod** (input_control) .................................. string \(\sim\) string
  - Method to perform the selection.
  - Default value: 'greedy'
  - List of values: SelectionMethod \(\in\) {'greedy', 'greedy_oscillating'}

- **Width** (input_control) .............................................. integer \(\sim\) integer
  - Width of the rectangle to which the gray values of the segmented character are zoomed.
  - Default value: 15

- **Height** (input_control) .............................................. integer \(\sim\) integer
  - Height of the rectangle to which the gray values of the segmented character are zoomed.
  - Default value: 16

- **GenParamName** (input_control) ...................................... string-array \(\sim\) string
  - Names of generic parameters to configure the selection process and the classifier.
  - Default value: []
  - List of values: GenParamName \(\in\) {'num_neighbors'}

- **GenParamValue** (input_control) ...................................... number-array \(\sim\) real / integer / string
  - Values of generic parameters to configure the selection process and the classifier.
  - Default value: []
  - Suggested values: GenParamValue \(\in\) {1, 2, 3}

- **OCRHandle** (output_control) ........................................ ocr_knn \(\sim\) handle
  - Trained OCR-k-NN classifier.

- **FeatureSet** (output_control) ........................................ string-array \(\sim\) string
  - Selected feature set, contains only entries from FeatureList.

- **Score** (output_control) .............................................. real-array \(\sim\) real
  - Achieved score using tow-fold cross-validation.

Result

If the parameters are valid, the operator `select_feature_set_trainf_knn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Alternatives

`select_feature_set_trainf_svm, select_feature_set_trainf_mlp`

Module OCR/OCV

**serialize_ocr_class_knn** ( : : OCRHandle : SerializedItemHandle )

**Serialize a k-NN-based OCR classifier.**

serialize_ocr_class_knn serializes a k-NN-based OCR classifier (see **fwrite_serialized_item** for an introduction of the basic principle of serialization). The same data that is written in a file by **write_ocr_class_knn** is converted to a serialized item. The OCR classifier is defined by the handle **OCRHandle**. The serialized OCR classifier is returned by the handle **SerializedItemHandle** and can be deserialized by **deserialize_ocr_class_knn**.

**Parameters**

- **OCRHandle** (input_control) ................................................................. ocr_knn \(\rightarrow\) handle
  Handle of the OCR classifier.
- **SerializedItemHandle** (output_control) ............................................ serialized_item \(\rightarrow\) handle
  Handle of the serialized item.

**Result**

If the parameters are valid, the operator **serialize_ocr_class_knn** returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

**trainf_ocr_class_knn, read_ocr_class_knn**

**Possible Successors**

create_class_knn, read_ocr_class_knn, deserialize_ocr_class_knn

**References**

Module OCR/OCV

**trainf_ocr_class_knn** ( : : OCRHandle, TrainingFile, GenParamName, GenParamValue : )

**Trains an k-NN classifier for an OCR task.**

trainf_ocr_class_knn trains the k-NN classifier **OCRHandle** with the training characters stored in the OCR training files given by **TrainingFile**. The training files must have been created, e.g., using **write_ocr_trainf**, before calling **trainf_ocr_class_knn**. Please, note that training characters that have no corresponding class in the classifier **OCRHandle** are discarded.

It is possible to set the number of trees via the parameters **GenParamName** and **GenParamValue** by 'num_trees'. The default value for the number of search trees is 4. A higher number of trees improves the accuracy of the search, but also increases the runtime. Normalization can be activated by setting 'normalization' in
GenParamName and and ‘true’ in GenParamValue. This will change the stored training data permanently. Therefore, adding data after the training is not possible.

<table>
<thead>
<tr>

**Example**

* Train an OCR classifier

```plaintext
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_knn (8, 10, 'constant', 'default', CharacterNames, [],
                      [], OCRHandle)
trainf_ocr_class_knn (OCRHandle, 'ocr.trf', [], [])
write_ocr_class_knn (OCRHandle, 'ocr.omc')
```

**Result**

If the parameters are valid, the operator `trainf_ocr_class_knn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

- create_ocr_class_knn, write_ocr_trainf, append_ocr_trainf, write_ocr_trainf_image

**Possible Successors**

**Module**

OCR/OCV
21.4. LEXICA

```cpp
write_ocr_class_knn ( : : OCRHandle, FileName : )
```

Write a k-NN classifier for an OCR task to a file.  

`write_ocr_class_knn` writes the k-NN classifier for an OCR task with the `OCRHandle` to the file given by `FileName`. If a file extension is not specified in `FileName` the default extension `.onc` is appended to `FileName`. `write_ocr_class_knn` is typically called after the classifier has been trained with `trainf_ocr_class_knn`. The classifier can be read with `read_ocr_class_knn`.

```plaintext
Parameters

- **OCRHandle** (input_control) .............................. `ocr_knn` ➔ `handle`  
  Handle of the k-NN classifier for an OCR task.

- **FileName** (input_control) .............................. `filename.write` ➔ `string`  
  File name.
  File extension: `.onc`

Result

If the parameters are valid, the operator `write_ocr_class_knn` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

OCR/OCV

21.4 Lexica

```cpp
clear_lexicon ( : : LexiconHandle : )
```

Clear a lexicon.

`clear_lexicon` clears a lexicon and releases its resources.

```plaintext
Parameters

- **LexiconHandle** (input_control) .............................. `lexicon` ➔ `handle`  
  Handle of the lexicon.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **LexiconHandle**
During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

See also
create_lexicon

Module
OCR/OCV

create_lexicon ( : : Name, Words : LexiconHandle )

Create a lexicon from a tuple of words.

create_lexicon creates a new lexicon based on a tuple of Words. By specifying a unique textual Name, you can later refer to the lexicon from syntax expressions like those used, e.g., by do_ocr_word_mlp.

Note that lexicon support in HALCON is currently not aimed at natural languages. Rather, it is intended as a post-processing step in OCR applications that only need to distinguish between a limited set of not more than a few thousand valid words, e.g., country or product names. MVTec itself does not provide any lexica.

Parameters

- **Name** (input_control) .................................................. string  string
  Unique name for the new lexicon.
  Default value: 'lex1'

- **Words** (input_control) ................................................. string-array  string
  Word list for the new lexicon.
  Default value: ['word1','word2','word3']

- **LexiconHandle** (output_control) .................................. lexicon  handle
  Handle of the lexicon.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

do_ocr_word_mlp, do_ocr_word_svm

Alternatives

import_lexicon

See also
lookup_lexicon, suggest_lexicon

Module
OCR/OCV

import_lexicon ( : : Name, FileName : LexiconHandle )

Create a lexicon from a text file.

import_lexicon creates a new lexicon based on a list of words in the file specified by FileName. The format of the file is a simple text file with one word per line. By specifying a unique textual Name, you can later refer to the lexicon from syntax expressions like those used, e.g., by do_ocr_word_mlp.

Note that lexicon support in HALCON is currently not aimed at natural languages. Rather, it is intended as a post-processing step in OCR applications that only need to distinguish between a limited set of not more than a
few thousand valid words, e.g., country or product names. When the lexicon file contains entries with special, non-ASCII characters, it is expected to be encoded in UTF-8. However, old lexicon files which use the local 8-bit encoding, can still be loaded as long as they contain at least one byte sequence, which cannot be misinterpreted as UTF-8 character. MVTec itself does not provide any lexica.

Parameters

◮ Name (input_control) ............................................................ string ~ string
   Unique name for the new lexicon.
   Default value: 'lex1'
◮ FileName (input_control) .................................................. filename.read ~ string
   Name of a text file containing words for the new lexicon.
   Default value: 'words.txt'
   File extension: .txt
◮ LexiconHandle (output_control) ....................................... lexicon ~ handle
   Handle of the lexicon.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

do_ocr_word_mlp, do_ocr_word_svm
 Alternatives

create_lexicon
 See also
lookup_lexicon, suggest_lexicon
 Module

inspect_lexicon ( : : LexiconHandle : Words )

Query all words from a lexicon.

inspect_lexicon returns a tuple of all words in the lexicon in the parameter Words.

Parameters

◮ LexiconHandle (input_control) ....................................... lexicon ~ handle
   Handle of the lexicon.
◮ Words (output_control) ................................................... string(-array) ~ string
   List of all words.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

Alternatives

lookup_lexicon
 See also
create_lexicon
 Module

OCR/OCV
**lookup_lexicon** ( : : LexiconHandle, Word : Found )

Check if a word is contained in a lexicon.

`lookup_lexicon` checks whether `Word` is contained in the lexicon `LexiconHandle`, and returns 1 in `Found` if the word is found, otherwise 0.

---

**Parameters**

- **LexiconHandle** (input_control) : handle
  Handle of the lexicon.
- **Word** (input_control) : string
  Word to be looked up.
  **Default value:** 'word'
- **Found** (output_control) : integer
  Result of the search.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---

**Alternatives**

`suggest_lexicon`

**See also**

`create_lexicon`

---

**Module**

OCR/OCV

---

**suggest_lexicon** ( : : LexiconHandle, Word : Suggestion,
NumCorrections )

Find a similar word in a lexicon.

`suggest_lexicon` compares `Word` to all words in the lexicon and calculates the minimum number of edit operations `NumCorrections` required to transform `Word` into a word from the lexicon. Valid edit operations are the insertion, deletion and replacement of characters. The most similar word found in the lexicon is returned in `Suggestion`. If there are multiple words with the same minimum number of corrections, only the first of those words is returned.

---

**Parameters**

- **LexiconHandle** (input_control) : handle
  Handle of the lexicon.
- **Word** (input_control) : string
  Word to be looked up.
  **Default value:** 'word'
- **Suggestion** (output_control) : string
  Most similar word found in the lexicon.
- **NumCorrections** (output_control) : integer
  Difference between the words in edit operations.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.
21.5 Neural Nets

| clear_ocr_class_mlp ( : : OCRHandle : ) |

Clear an OCR classifier.

clear_ocr_class_mlp clears the OCR classifier given by OCRHandle that was created with create_ocr_class_mlp and frees all memory required for the classifier. After calling clear_ocr_class_mlp, the classifier can no longer be used. The handle OCRHandle becomes invalid.

Parameters

• OCRHandle (input_control) : ocr_mlp(-array) ~ handle Handle of the OCR classifier.

Result

If OCRHandle is valid, the operator clear_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

OCR/OCV

create_ocr_class_mlp ( : : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, NumHidden, Preprocessing, NumComponents, RandSeed : OCRHandle )

Create an OCR classifier using a multilayer perceptron.

create_ocr_class_mlp creates an OCR classifier that uses a multilayer perceptron (MLP). The handle of the OCR classifier is returned in OCRHandle.
For a description on how an MLP works, see `create_class_mlp`. `create_ocr_class_mlp` creates an MLP with `OutputFunction = 'softmax'`. The length of the feature vector of the MLP (NumInput in `create_class_mlp`) is determined from the features that are used for the OCR, which are passed in `Features`. The features are described below. The number of units in the hidden layer is determined by `NumHidden`. The number of output variables of the MLP (NumOutput in `create_class_mlp`) is determined from the names of the characters to be used in the OCR, which are passed in `Characters`. As described with `create_class_mlp`, the parameters `Preprocessing` and `NumComponents` can be used to specify a preprocessing of the data (i.e., the feature vectors). The OCR already approximately normalizes the features. Hence, `Preprocessing` can typically be set to `none`. The parameter `RandSeed` has the same meaning as in `create_class_mlp`. Furthermore, like for general MLP classifiers (see `create_class_mlp` and `set_regularization_params_class_mlp`), it may be desirable to regularize OCR classifiers. This can be achieved by calling `set_regularization_params_ocr_class_mlp` before training the OCR classifier. In addition, like for general MLP classifiers (see `create_class_mlp` and `set_rejection_params_class_mlp`), it might be desirable to equip the OCR classifiers with the capability to reject unknown characters. The rejection class is by convention an additional symbol chr(26) that must be provided in `Characters`. The parameters of the rejection class can be set by calling `set_rejection_params_ocr_class_mlp` before training the OCR classifier.

The features to be used for the classification are determined by `Features`. `Features` can contain a tuple of several feature names. Each of these feature names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., `'pixel_invar'`). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by `WidthCharacter` and `HeightCharacter`. The interpolation to be used for the transformation is determined by `Interpolation`. It has the same meaning as in `affine_trans_image`. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, `Interpolation = 'constant'` should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, large sizes will lead to the fact that small segmentation errors will have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, which leads to the fact that the character is zoomed differently than the characters in the training set. In most applications, sizes between $6 \times 8$ and $10 \times 14$ should be used.

The parameter `Features` can contain the following feature names for the classification of the characters.

- `'default` 'ratio' and `'pixel_invar` are selected.
- `'pixel'` Gray values of the character (`WidthCharacter × HeightCharacter` features).
- `'pixel_invar'` Gray values of the character with maximum scaling of the gray values (`WidthCharacter × HeightCharacter` features).
- `'pixel_binary'` Region of the character as a binary image zoomed to a size of `WidthCharacter × HeightCharacter` (`WidthCharacter × HeightCharacter` features).
- `'gradient_8dir'` Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a $5 \times 5$ grid are extracted from each channel. These samples are used as features (200 features).
- `'projection_horizontal'` Horizontal projection of the gray values (see `gray_projections`, `HeightCharacter` features).
- `'projection_horizontal_invar'` Maximally scaled horizontal projection of the gray values (`HeightCharacter` features).
- `'projection_vertical'` Vertical projection of the gray values (see `gray_projections`, `WidthCharacter` features).
- `'projection_vertical_invar'` Maximally scaled vertical projection of the gray values (`WidthCharacter` features).
- `'ratio'` Aspect ratio of the character (see `height_width_ratio`, 1 feature).
- `'anisometry'` Anisometry of the character (see `eccentricity`, 1 feature).
- `'width'` Width of the character before scaling the character to the standard size (not scale-invariant, see `height_width_ratio`, 1 feature).
- `'height'` Height of the character before scaling the character to the standard size (not scale-invariant, see `height_width_ratio`, 1 feature).
'zoom_factor' Difference in size between the character and the values of WidthCharacter and HeightCharacter (not scale-invariant, 1 feature).

'foreground' Fraction of pixels in the foreground (1 feature).

'foreground_grid_9' Fraction of pixels in the foreground in a $3 \times 3$ grid within the smallest enclosing rectangle of the character (9 features).

'foreground_grid_16' Fraction of pixels in the foreground in a $4 \times 4$ grid within the smallest enclosing rectangle of the character (16 features).

'compactness' Compactness of the character (see compactness, 1 feature).

'convexity' Convexity of the character (see convexity, 1 feature).

'moments_region_2nd_invar' Normalized 2nd moments of the character (see moments_region_2nd_invar, 3 features).

'moments_region_2nd_rel_invar' Normalized 2nd relative moments of the character (see moments_region_2nd_rel_invar, 2 features).

'moments_region_3rd_invar' Normalized 3rd moments of the character (see moments_region_3rd_invar, 4 features).

'moments_central' Normalized central moments of the character (see moments_region_central, 4 features).

'moments_gray_plane' Normalized gray value moments and the angle of the gray value plane (see moments_gray_plane, 4 features).

'phi' Sinus and cosinus of the orientation (angle) of the character (see elliptic_axis, 2 feature).

'num_connect' Number of connected components (see connect_and_holes, 1 feature).

'num_holes' Number of holes (see connect_and_holes, 1 feature).

'cooc' Values of the binary cooccurrence matrix (see gen_cooc_matrix, 8 features).

'num_runs' Number of runs in the region normalized by the height (1 feature).

'chord_histo' Frequency of the runs per row (not scale-invariant, HeightCharacter features).

After the classifier has been created, it is trained using trainf_ocr_class_mlp. After this, the classifier can be saved using write_ocr_class_mlp. Alternatively, the classifier can be used immediately after training to classify characters using do_ocr_single_class_mlp or do_ocr_multi_class_mlp.

HALCON provides a number of pretrained OCR classifiers (see the "Solution Guide I", chapter 'OCR', section 'Pretrained OCR Fonts'). These pretrained OCR classifiers can be read directly with read_ocr_class_mlp and make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Therefore, it is recommended to try if one of the pretrained OCR classifiers can be used successfully. If this is the case, it is not necessary to create and train an OCR classifier.

A comparison of the MLP and the support vector machine (SVM) (see create_ocr_class_svm) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

**Parameters**

- `WidthCharacter` (input_control) ............................................................ integer $\sim$ integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 8
  Suggested values: $\text{WidthCharacter} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20\}$
  Typical range of values: $4 \leq \text{WidthCharacter} \leq 20$

- `HeightCharacter` (input_control) ............................................................ integer $\sim$ integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 10
  Suggested values: $\text{HeightCharacter} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20\}$
  Typical range of values: $4 \leq \text{HeightCharacter} \leq 20$

- `Interpolation` (input_control) ............................................................. string $\sim$ string
  Interpolation mode for the zooming of the characters.
  Default value: 'constant'
  List of values: $\text{Interpolation} \in \{\text{`nearest_neighbor'}, \text{`bilinear'}, \text{`bicubic'}, \text{`constant'}, \text{`weighted'}\}$
Features (input_control) ................. string(-array)  ~ string
Features to be used for classification.
Default value: 'default'

Characters (input_control) ......................... string-array  ~ string
All characters of the character set to be read.
Default value: ['0','1','2','3','4','5','6','7','8','9']

NumHidden (input_control) ......................... integer  ~ integer
Number of hidden units of the MLP.
Default value: 80
Suggested values: NumHidden ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 150}
Restriction: NumHidden >= 1

Preprocessing (input_control) ....................... string  ~ string
Type of preprocessing used to transform the feature vectors.
Default value: 'none'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

NumComponents (input_control) ....................... integer  ~ integer
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = 'none' and Preprocessing = 'normalization').
Default value: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

RandSeed (input_control) ............................ integer  ~ integer
Seed value of the random number generator that is used to initialize the MLP with random values.
Default value: 42

OCRHandle (output_control) ........................... ocr_mlp  ~ handle
Handle of the OCR classifier.

Example

read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
  Classes := [Classes,gen_tuple_const(20,chr(ord('a')+J))]
endfor
Classes := [Classes,gen_tuple_const(20,'.')]  
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 20, \  
  'none', 81, 42, OCRHandle)
trainf_ocr_class_mlp (OCRHandle, 'letters.trf', 100, 0.01, 0.01, Error, \  
  ErrorLog)
* Re-classify the characters in the image.
do_ocr_multi_class_mlp (Characters, Image, OCRHandle, Class, Confidence)
If the parameters are valid, the operator `create_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

**Possible Successors**

- `trainf_ocr_class_mlp`
- `set_regularization_params_ocr_class_mlp`
- `set_rejection_params_ocr_class_mlp`

**Alternatives**

- `create_ocr_class_svm`

**Module**

OCR/OCV

### `deserialize_ocr_class_mlp`

Deserialize a serialized MLP-based OCR classifier.

`deserialize_ocr_class_mlp` deserializes a MLP-based OCR classifier, that was serialized by `serialize_ocr_class_mlp` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCR classifier with the handle `OCRHandle`.

**Parameters**

- `SerializedItemHandle` (input_control) 
  Handle of the serialized item.
- `OCRHandle` (output_control) 
  Handle of the OCR classifier.

**Result**

If the parameters are valid, the operator `deserialize_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

**Possible Predecessors**

- `fread_serialized_item`
- `receive_serialized_item`
- `serialize_ocr_class_mlp`

**Possible Successors**

- `do_ocr_single_class_mlp`
- `do_ocr_multi_class_mlp`
- `clear_ocr_class_mlp`

- `serialize_ocr_class_mlp`

**Module**

OCR/OCV
Classify multiple characters with an OCR classifier.

do_ocr_multi_class_mlp computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. In contrast to do_ocr_single_class_mlp, do_ocr_multi_class_mlp can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_mlp to classify single characters. However, do_ocr_multi_class_mlp can only return the best class of each character. Because the confidences can be interpreted as probabilities (see classify_class_mlp and evaluate_class_mlp), and it is therefore easy to check whether a character has been classified with too much uncertainty, this is usually not a disadvantage, except in cases where the classes overlap so much that in many cases the second best class must be examined to be able to decide the class of the character. In these cases, do_ocr_single_class_mlp should be used.

A string of the number ‘\032’ (alternatively displayed as ‘\0x1A’) in Class signifies that the region has been classified as rejection class.

Before calling do_ocr_multi_class_mlp, the classifier must be trained with trainf_ocr_class_mlp.

---

**Parameters**

- **Character** (input_object) .......................................................... region(-array) ↸ object
  Characters to be recognized.
- **Image** (input_object) .......................................................... singlechannelimage ↸ object : byte / uint2
  Gray values of the characters.
- **OCRHandle** (input_control) .................................................. ocr_mlp ↸ handle
  Handle of the OCR classifier.
- **Class** (output_control) ...................................................... string(-array) ↸ string
  Result of classifying the characters with the MLP.

  **Number of elements:** Class == Character

- **Confidence** (output_control) ................................................ real(-array) ↸ real
  Confidence of the class of the characters.

  **Number of elements:** Confidence == Character

---

**Result**

If the parameters are valid, the operator do_ocr_multi_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

---

**Possible Predecessors**

---

**Module**

OCR/OCV

---

**do_ocr_single_class_mlp** ( Character, Image : : OCRHandle, Num : Class, Confidence )

Classify a single character with an OCR classifier.
do_ocr_single_class_mlp computes the best Num classes of the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Because multiple classes may be returned by do_ocr_single_class_mlp, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_mlp must be used. Because do_ocr_multi_class_mlp typically is faster than a loop with do_ocr_single_class_mlp and because the confidences can be interpreted as probabilities (see classify_class_mlp and evaluate_class_mlp), and it is therefore easy to check whether a character has been classified with too much uncertainty, in most cases do_ocr_multi_class_mlp should be used, unless the second-best class should be examined explicitly.

A string of the number ‘\032’ (alternatively displayed as ‘\0r1A’) in Class signifies that the region has been classified as rejection class.

Before calling do_ocr_single_class_mlp, the classifier must be trained with trainf_ocr_class_mlp.

---------- Parameters ----------

- **Character** (input_object) .......................................................... region \(\sim\) object
  Character to be recognized.
- **Image** (input_object) .................................................. singlechannelimage \(\sim\) object : byte / uint2
  Gray values of the character.
- **OCRHandle** (input_control) .................................................. ocr_mlp \(\sim\) handle
  Handle of the OCR classifier.
- **Num** (input_control) .................................................. integer-array \(\sim\) integer
  Number of best classes to determine.
  Default value: 1
  Suggested values: \(\text{Num} \in \{1, 2, 3, 4, 5\}\)
- **Class** (output_control) .................................................. string(-array) \(\sim\) string
  Result of classifying the character with the MLP.
- **Confidence** (output_control) ........................................... real(-array) \(\sim\) real
  Confidence(s) of the class(es) of the character.

---------- Result ----------

If the parameters are valid, the operator do_ocr_single_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---------- Execution Information ----------

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

---------- Module ----------

OCR/OCV

do_ocr_word_mlp ( Character, Image : : OCRHandle, Expression, NumAlternatives, NumCorrections : Class, Confidence, Word, Score )

Classify a related group of characters with an OCR classifier.
do_ocr_word_mlp works like do_ocr_multi_class_mlp insofar as it computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. In contrast to do_ocr_multi_class_mlp, do_ocr_word_mlp treats the group of characters as an entity which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or import_lexicon, by specifying the name of the lexicon in angular brackets as in '<mylexicon>'. If the Expression is of any other form, it is interpreted as a regular expression with the same syntax as specified for tuple_regexp_match. Note that you will usually want to use an expression of the form '^...$' when using variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to tuple_regexp_match, do_ocr_word_mlp does not support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_mlp attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives used are identical to those returned by do_ocr_single_class_mlp for a single character. It does so by testing all possible corrections for which the classification result is changed for at most NumCorrections character regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

\[
\text{Score} = 1.0 - \text{PenaltyCorrections} - \text{PenaltyAlternatives}
\]

\[
\text{PenaltyCorrections} = \alpha \times \text{num corr}
\]

\[
\text{PenaltyAlternatives} = \alpha \times \beta \times \text{num alt}
\]

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

\[
\alpha = \frac{1}{\text{NumCorrections} + 1}
\]

\[
\beta = \frac{1}{\text{NumCorrections} \times (\text{NumAlternatives} - 1) + 2}
\]

Note that this is a combinatorial score which does not reflect the original Confidence of the best Class.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

---

Parameters

- **Character** (input_object) ......................... region(-array) → object
  Characters to be recognized.
- **Image** (input_object) ......................... singlechannelimage → object : byte / uint2
  Gray values of the characters.
- **OCRHandle** (input_control) ....................... ocr_mlp → handle
  Handle of the OCR classifier.
- **Expression** (input_control) ....................... string → string
  Expression describing the allowed word structure.
21.5. NEURAL NETS

- **NumAlternatives** (input_control) ........................................................... integer \(\rightsquigarrow\) integer
  Number of classes per character considered for the internal word correction.
  **Default value:** 3
  **Suggested values:** NumAlternatives \(\in\) \{3, 4, 5\}
  **Typical range of values:** \(1 \leq\) NumAlternatives

- **NumCorrections** (input_control) ........................................................... integer \(\rightsquigarrow\) integer
  Maximum number of corrected characters.
  **Default value:** 2
  **Suggested values:** NumCorrections \(\in\) \{1, 2, 3, 4, 5\}
  **Typical range of values:** \(0 \leq\) NumCorrections

- **Class** (output_control) ................................................................. string(-array) \(\rightsquigarrow\) string
  Result of classifying the characters with the MLP.
  **Number of elements:** Class \(==\) Character

- **Confidence** (output_control) .......................................................... real(-array) \(\rightsquigarrow\) real
  Confidence of the class of the characters.
  **Number of elements:** Confidence \(==\) Character

- **Word** (output_control) ................................................................. string \(\rightsquigarrow\) string
  Word text after classification and correction.

- **Score** (output_control) ................................................................. real \(\rightsquigarrow\) real
  Measure of similarity between corrected word and uncorrected classification results.

---

**Complexity**
The complexity of checking all possible corrections is of magnitude \(O((n \ast a)^{\min(c,n)})\), where \(a\) is the number of alternatives, \(n\) is the number of character regions, and \(c\) is the number of allowed corrections. However, to guard against a near-infinite loop in case of large \(n\), \(c\) is internally clipped to 5, 3, or 1 if \(a \ast n >= 30, 60,\) or 90, respectively.

---

**Result**
If the parameters are valid, the operator `do_ocr_word_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

---

**Execution Information**

---

**get_features_ocr_class_mlp** (Character : : OCRHandle,
  Transform : : Features )

`get_features_ocr_class_mlp` computes the features of the character given by Character with the OCR classifier OCRHandle and returns them in Features. In contrast to `do_ocr_single_class_mlp` and `do_ocr_multi_class_mlp`, the character is passed as a single image object. Hence, before calling `get_features_ocr_class_mlp`, `reduce_domain` must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in `create_ocr_class_mlp` for the classifier should be applied (Transform = 'true') or whether the untransformed features should be returned (Transform = 'false'). `get_features_ocr_class_mlp` can be used to inspect the features that are used for the classification.
Parameters

- **Character** (input_object) ........................................... singlechannelimage  \(\sim\) object : byte / uint2
  Input character.

- **OCRHandle** (input_control) ........................................... ocr_mlp  \(\sim\) handle
  Handle of the OCR classifier.

- **Transform** (input_control) ........................................... string  \(\sim\) string
  Should the feature vector be transformed with the preprocessing?
  Default value: ’true’
  List of values: Transform \(\in\) {'true', 'false'}

- **Features** (output_control) ........................................... real-array  \(\sim\) real
  Feature vector of the character.

Result

If the parameters are valid, the operator get_features_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_params_ocr_class_mlp ( : : OCRHandle : WidthCharacter,
                         HeightCharacter, Interpolation, Features, Characters,
                         NumHidden, Preprocessing, NumComponents )

Return the parameters of an OCR classifier.

get_params_ocr_class_mlp returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_mlp. This is particularly useful if the classifier was read with read_ocr_class_mlp. The output of get_params_ocr_class_mlp can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_mlp.

Parameters

- **OCRHandle** (input_control) ........................................... ocr_mlp  \(\sim\) handle
  Handle of the OCR classifier.

- **WidthCharacter** (output_control) ........................................... integer  \(\sim\) integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.

- **HeightCharacter** (output_control) ........................................... integer  \(\sim\) integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.

- **Interpolation** (output_control) ........................................... string  \(\sim\) string
  Interpolation mode for the zooming of the characters.

- **Features** (output_control) ........................................... string(-array)  \(\sim\) string
  Features to be used for classification.

- **Characters** (output_control) ........................................... string-array  \(\sim\) string
  Characters of the character set to be read.

- **NumHidden** (output_control) ........................................... integer  \(\sim\) integer
  Number of hidden units of the MLP.
NEURAL NETS

2049

Preprocessing (output_control) string
Type of preprocessing used to transform the feature vectors.

NumComponents (output_control) integer
Preprocessing parameter: Number of transformed features.

Result

Module
OCR/OCV

get_prep_info_ocr_class_mlp ( : : OCRHandle, TrainingFile,
   Preprocessing : InformationCont, CumInformationCont )

Compute the information content of the preprocessed feature vectors of an OCR classifier.

get_prep_info_ocr_class_mlp computes the information content of the training vectors that have been transformed with the preprocessing given by Preprocessing. Preprocessing can be set to ‘principal_components’ or ‘canonical_variates’. The OCR classifier OCRHandle must have been created with create_ocr_class_mlp. The preprocessing methods are described with create_class_mlp. The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (NumInput for ‘principal_components’ and min(NumOutput − 1, NumInput) for ‘canonical_variates’, see create_class_mlp), and is returned in InformationCont as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of CumInformationCont, i.e., CumInformationCont contains the sums of the first n elements of InformationCont. To use get_prep_info_ocr_class_mlp, a sufficient number of samples must be stored in the training files given by TrainingFile (see write_ocr_trainf). InformationCont and CumInformationCont can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the total data. This can be decided easily from the first value of CumInformationCont that lies above x%. The number thus obtained can be used as the value for NumComponents in a new call to create_ocr_class_mlp. The call to get_prep_info_ocr_class_mlp already requires the creation of a classifier, and hence the setting of NumComponents in create_ocr_class_mlp to an initial value. However, if get_prep_info_ocr_class_mlp is called it is typically not known how many components are relevant, and hence how to set NumComponents in this call. Therefore, the following two-step approach should typically be used to select NumComponents: In a first step, a classifier with the maximum number for NumComponents is created (NumInput for ‘principal_components’ and min(NumOutput − 1, NumInput) for ‘canonical_variates’). Then, the training samples are saved in a training file using write_ocr_trainf. Subsequently, get_prep_info_ocr_class_mlp is used to determine the information content of the components, and with this NumComponents. After this, a new classifier with the desired number of components is created, and the classifier is trained with trainf_ocr_class_mlp.
Parameters

- **OCRHandle** (input_control) \(\sim\) handle
  Handle of the OCR classifier.

- **TrainingFile** (input_control) \(\sim\) string
  Names of the training files.
  Default value: 'ocr.trf'
  File extension: .trf, .otr

- **Preprocessing** (input_control) \(\sim\) string
  Type of preprocessing used to transform the feature vectors.
  Default value: 'principal_components'
  List of values: Preprocessing \(\in\) {'principal_components', 'canonical_variates'}

- **InformationCont** (output_control) \(\sim\) real-array
  Relative information content of the transformed feature vectors.

- **CumInformationCont** (output_control) \(\sim\) real-array
  Cumulative information content of the transformed feature vectors.

Example

* Create the initial OCR classifier.
  read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
  create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, 
    'canonical_variates', |CharacterNames|, 42, OCRHandle)
* Get the information content of the transformed feature vectors.
  get_prep_info_ocr_class_mlp (OCRHandle, 'ocr.trf', 'canonical_variates', 
    InformationCont, CumInformationCont)
* Determine the number of transformed components.
  NumComp = [...]  
* Create the final OCR classifier.
  create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, 
    'canonical_variates', NumComp, 42, OCRHandle)
* Train the final classifier.
  trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, ErrorLog)
  write_ocr_class_mlp (OCRHandle, 'ocr.omc')

Result

If the parameters are valid, the operator get_prep_info_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

get_prep_info_ocr_class_mlp may return the error 9211 (Matrix is not positive definite) if Preprocessing = 'canonical_variates' is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV
get_regularization_params_ocr_class_mlp ( : : OCRHandle,  
GenParamName : GenParamValue )

Return the regularization parameters of an OCR classifier.

get_regularization_params_ocr_class_mlp returns the regularization parameters of an OCR classifier that were specified with set_regularization_params_ocr_class_mlp. Furthermore, get_regularization_params_ocr_class_mlp returns the parameters that were determined by an automatic determination of the regularization parameters. For a description of the parameters, see set_regularization_params_ocr_class_mlp.

Parameters

- OCRHandle (input_control) .......................................................... ocr_mlp => handle
  Handle of the OCR classifier.
- GenParamName (input_control) .................................................. string => string
  Name of the regularization parameter to return.
    Default value: 'weight_prior'
    List of values: GenParamName ∈ ['weight_prior', 'num_well_determined_params', 'fraction_well_determined_params', 'num_outer_iterations', 'num_inner_iterations']
- GenParamValue (output_control) .............................................. number(-array) => real / integer
  Value of the regularization parameter.

Result

If the parameters are valid, the operator get_regularization_params_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

GenParamName : GenParamValue )

Return the rejection class parameters of an OCR classifier.

generate_rejection_params_ocr_class_mlp returns the rejection class parameters of an OCR classifier that were specified with set_rejection_params_ocr_class_mlp. For a description of the parameters, see set_rejection_params_ocr_class_mlp and set_rejection_params_class_mlp.

Parameters

- OCRHandle (input_control) .......................................................... ocr_mlp => handle
  Handle of the OCR classifier.
- GenParamName (input_control) .................................................. string(-array) => string
  Name of the general parameter.
    Default value: 'sampling_strategy'
    List of values: GenParamName ∈ ['sampling_strategy', 'hyperbox_tolerance', 'rejection_sample_factor', 'random_seed', 'rejection_class_index']
- GenParamValue (output_control) .............................................. string(-array) => string
  Value of the general parameter.
If the parameters are valid, the operator `get_rejection_params_ocr_class_mlp` returns the value 2 (\texttt{H\_MSG\_TRUE}). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

**Possible Successors**

`trainf_ocr_class_mlp`

**Module**

OCR/OCV

---

**read_ocr_class_mlp** ( : : FileName : OCRHandle )

Read an OCR classifier from a file.

`read_ocr_class_mlp` reads an OCR classifier that has been stored with `write_ocr_class_mlp`. Since the training of an OCR classifier can consume a relatively long time, the classifier is typically trained in an offline process and written to a file with `write_ocr_class_mlp`. In the online process the classifier is read with `read_ocr_class_mlp` and subsequently used for classification with `do_ocr_single_class_mlp` or `do_ocr_multi_class_mlp`.

HALCON provides a number of pretrained OCR classifiers (see the “Solution Guide I“, chapter ‘OCR’, section ‘Pretrained OCR Fonts’). These pretrained OCR classifiers make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Note that the pretrained OCR classifiers were trained with symbols that are printed dark on light.

**Parameters**

- **FileName** (input_control) 
  File name.

  **Suggested values:**
  

**File extension:** .omc, .fnt

- **OCRHandle** (output_control) 
  Handle of the OCR classifier.
21.5. NEURAL NETS

Result

If the parameters are valid, the operator `read_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

create_ocr_class_mlp, write_ocr_class_mlp, read_class_mlp, write_class_mlp

Module

OCR/OCV

```
select_feature_set_trainf_mlp ( : : TrainingFile, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score )
```

Selects an optimal combination of features to classify OCR data.

`select_feature_set_trainf_mlp` selects an optimal combination of features, to classify the OCR data given in the training file `TrainingFile` with a multilayer perceptron, for details see `create_ocr_class_mlp`.

Possible features are all OCR features listed and explained in `create_ocr_class_mlp`. All candidates which should be tested can be specified in `FeatureList`. A subset of these features is returned as selected features in `FeatureSet`.

`select_feature_set_trainf_mlp` is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator `select_feature_set_mlp`.

The selection method `SelectionMethod` is either a greedy search 'greedy' (iteratively add the feature with highest gain) or the dynamically oscillating search 'greedy_oscillating' (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method 'greedy' is generally preferable, since it is faster. Only in cases when a large training set is available the method 'greedy_oscillating' might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in `Score`.

The parameters `GenParamName` and `GenParamValue` allow to adapt the setting of the number of hidden neurons in the MLP with 'num_hidden'. The default value is 80, a higher value leads to longer training times but might lead to a more expressive classifier.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_trainf_mlp` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.
### Parameters

- **TrainingFile** (input_control) .......................................................... filename.read(-array) ⇒ string
  Names of the training files.
  Default value: ”
  File extension: .trf, .otr

- **FeatureList** (input_control) .......................................................... string(-array) ⇒ string
  List of features that should be considered for selection.

- **SelectionMethod** (input_control) .................................................. string
  Method to perform the selection.
  Default value: ‘greedy’
  **List of values:** SelectionMethod ∈ {'greedy', 'greedy_oscillating'}

- **Width** (input_control) ................................................................. integer ⇒ integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 15

- **Height** (input_control) ............................................................... integer ⇒ integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 16

- **GenParamName** (input_control) ..................................................... string-array ⇒ string
  Names of generic parameters to configure the selection process and the classifier.
  Default value: []
  **List of values:** GenParamName ∈ {'nu'}

- **GenParamValue** (input_control) .................................................... number-array ⇒ real / integer / string
  Values of generic parameters to configure the selection process and the classifier.
  Default value: []
  **Suggested values:** GenParamValue ∈ {'0.1'}

- **OCRHandle** (output_control) ......................................................... ocr_mlp ⇒ handle
  Trained OCR-MLP classifier.

- **FeatureSet** (output_control) ....................................................... string-array ⇒ string
  Selected feature set, contains only entries from FeatureList.

- **Score** (output_control) ............................................................... real-array ⇒ real
  Achieved score using tow-fold cross-validation.

### Result
If the parameters are valid, the operator select_feature_set_trainf_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

### Alternatives

select_feature_set_trainf_svm, select_feature_set_trainf_knn
Select an optimal combination of features to classify OCR data from a (protected) training file.

select_feature_set_trainf_mlp_protected selects an optimal combination of features to classify the data given in the training files TrainingFile with a multilayer perceptron (MLP). Its functionality corresponds to the functionality of select_feature_set_trainf_mlp, with the addition that select_feature_set_trainf_mlp_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator's functionality see select_feature_set_trainf_mlp. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_mlp_protected may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

- **TrainingFile** (input_control) ......................... filename.read(-array) ⇒ string
  Names of the training files.
  Default value: ”
  File extension: .trf, .otr
- **Password** (input_control) .......................... string(-array) ⇒ string
  Passwords for protected training files.
- **FeatureList** (input_control) ......................... string(-array) ⇒ string
  List of features that should be considered for selection.
  Default value:
- **SelectionMethod** (input_control) .................. string ⇒ string
  Method to perform the selection.
  Default value: ‘greedy’
  List of values: SelectionMethod ∈ \{‘greedy’, ‘greedy_oscillating’\}
- **Width** (input_control) .............................. integer ⇒ integer
  Width of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 15
CHAPTER 21 OCR

- **Height** (input_control) .......................................................... integer \( \sim \) integer
  Height of the rectangle to which the gray values of the segmented character are zoomed.
  Default value: 16

- **GenParamName** (input_control) ................................................... string-array \( \sim \) string
  Names of generic parameters to configure the selection process and the classifier.
  Default value: []
  List of values: GenParamName \( \in \) \{'nu'\}

- **GenParamValue** (input_control) .................................................. number-array \( \sim \) real / integer / string
  Values of generic parameters to configure the selection process and the classifier.
  Default value: []
  Suggested values: GenParamValue \( \in \) \{'0.1'\}

- **OCRHandle** (output_control) .................................................. ocr_mlp \( \sim \) handle
  Trained OCR-MLP classifier.

- **FeatureSet** (output_control) .................................................. string-array \( \sim \) string
  Selected feature set, contains only entries from FeatureList.

- **Score** (output_control) .................................................. real-array \( \sim \) real
  Achieved score using tow-fold cross-validation.

--- Result

If the parameters are valid, the operator `select_feature_set_trainf_mlp_protected` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

--- Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

OCR/OCV

```plaintext
serialize_ocr_class_mlp ( : : OCRHandle : SerializedItemHandle )
```

**Serialize a MLP-based OCR classifier.**

`serialize_ocr_class_mlp` serializes a MLP-based OCR classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ocr_class_mlp` is converted to a serialized item. The OCR classifier is defined by the handle `OCRHandle`. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr_class_mlp`.

--- Parameters

- **OCRHandle** (input_control) .................................................. ocr_mlp \( \sim \) handle
  Handle of the OCR classifier.

- **SerializedItemHandle** (output_control) .................................. serialized_item \( \sim \) handle
  Handle of the serialized item.
If the parameters are valid, the operator `serialize_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

### `set_regularization_params_ocr_class_mlp` ( : : OCRHandle, GenParamName, GenParamValue : )

Set the regularization parameters of an OCR classifier.

`set_regularization_params_ocr_class_mlp` sets the regularization parameters of the OCR classifier passed in `OCRHandle`. The regularization parameter to be set is specified with `GenParamName`. Its value is specified with `GenParamValue`.

As described at `create_class_mlp`, it may be desirable to regularize the OCR classifier (i.e., the MLP of the OCR classifier) to enforce a smoother transition of the confidence between the different classes and to prevent overfitting of the OCR classifier to the training data. To achieve this, a penalty for large MLP weights (which are the main reason for very sharp transitions between classes) can be added to the training of the OCR classifier in `trainf_ocr_class_mlp` by setting `GenParamName` to ‘weight prior’ and setting `GenParamValue` to a value > 0. Furthermore, the regularization parameters can be determined automatically. For details, see `set_regularization_params_class_mlp`. If the regularization parameters should be determined automatically, please carefully note the advice in `set_regularization_params_class_mlp` on how to select the parameters `NumHidden` of the MLP and ‘num_outer_iterations’ and on the memory and runtime implications of automatically determining the regularization parameters on the runtime of the training of the OCR classifier.

### Parameters

- **OCRHandle** (input_control) : `handle` Handle of the OCR classifier.
- **GenParamName** (input_control) : `string` Name of the regularization parameter to return.
  - **Default value:** ‘weight prior’
  - **List of values:** `GenParamName` ∈ {‘weight prior’, ‘num_outer_iterations’, ‘num_inner_iterations’}
- **GenParamValue** (input_control) : `number(-array)` Value of the regularization parameter.
  - **Default value:** 1.0
  - **Suggested values:** `GenParamValue` ∈ {0.01, 0.1, 1.0, 10.0, 100.0, 0, 1, 2, 3, 5, 10, 15, 20}

### Example

* This example shows how to determine the regularization parameters automatically without examining the convergence of the regularization parameters.
* Create the OCR classifier.
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, \40, 'none', |CharacterNames|, 42, OCRHandle)

* Set up the automatic determination of the regularization parameters.
set_regularization_params_ocr_class_mlp (OCRHandle, 'weight_prior', \[0.01,0.01,0.01,0.01]
set_regularization_params_ocr_class_mlp (OCRHandle, \'num_outer_iterations', 10)

* Train the classifier.
trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, \ErrorLog)

* Read out the estimate of the number of well-determined parameters.
get_regularization_params_ocr_class_mlp (OCRHandle, \'fraction_well_determined_params', \FractionParams)

* If FractionParams differs substantially from 1, consider reducing NumHidden appropriately and consider performing a preprocessing that reduces the number of input variables to the net, i.e., canonical variates or principal components.
write_ocr_class_mlp (OCRHandle, 'ocr.omc')

* This example shows how to determine the regularization parameters automatically while examining the convergence of the regularization parameters.
* Create the OCR classifier.
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, \40, 'none', |CharacterNames|, 42, OCRHandle)

* Set up the automatic determination of the regularization parameters.
set_regularization_params_ocr_class_mlp (OCRHandle, 'weight_prior', \[0.01,0.01,0.01,0.01]
set_regularization_params_ocr_class_mlp (OCRHandle, \'num_outer_iterations', 1)

for OuterIt := 1 to 10 by 1
    * Train the classifier.
    trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, \ErrorLog)
    * Read out the regularization parameters
    get_regularization_params_ocr_class_mlp (OCRHandle, \'weight_prior', \WeightPrior)
    * Inspect the regularization parameters manually for convergence and exit the loop manually if they have converged.
    * [...] endfor

* Read out the estimate of the number of well-determined parameters.
get_regularization_params_ocr_class_mlp (OCRHandle, \'fraction_well_determined_params', \FractionParams)

* If FractionParams differs substantially from 1, consider reducing NumHidden appropriately and consider performing a preprocessing that
* reduces the number of input variables to the net, i.e., canonical
* variates or principal components.

```cpp
write_ocr_class_mlp (OCRHandle, 'ocr.omc')
```

**Result**

If the parameters are valid, the operator `set_rejection_params_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

**Possible Predecessors**

- `trainf_ocr_class_mlp`

**Module**

OCR/OCV

---

```cpp
set_rejection_params_ocr_class_mlp ( : : OCRHandle, GenParamName, GenParamValue ; )
```

*Set the rejection class parameters of an OCR classifier.*

The function `set_rejection_params_ocr_class_mlp` sets the rejection class parameters of the OCR classifier passed in `OCRHandle`. The parameter to be set is specified with `GenParamName`. Its value is specified with `GenParamValue`. For some OCR applications it is important to know, if a letter to be classified is similar to the training set or not. If a letter is different to the training set, then it can be classified a rejection class. This additional rejection class must be specified as an additional character in `create_ocr_class_mlp`. For details on how to specify a rejection class, see `set_rejection_params_class_mlp`.

**Parameters**

- **OCRHandle** (input_control) : Handle of the OCR classifier.
- **GenParamName** (input_control) : Name of the general parameter.
  - Default value: 'sampling_strategy'
  - List of values: GenParamName ∈ {'sampling_strategy', 'hyperbox_tolerance', 'rejection_sample_factor', 'random_seed', 'rejection_class_index'}
- **GenParamValue** (input_control) : Value of the general parameter.
  - Default value: 'hyperbox_around_all_classes'
  - List of values: GenParamValue ∈ {'no_rejection_class', 'hyperbox_around_all_classes', 'hyperbox_around_each_class', 'hyperbox_ring_around_each_class'}

**Result**

If the parameters are valid, the operator `set_rejection_params_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator modifies the state of the following input parameter:

• OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Successors

trainf_ocr_class_mlp

Module

OCR/OCV

trainf_ocr_class_mlp ( : : OCRHandle, TrainingFile, MaxIterations, WeightTolerance, ErrorTolerance : Error, ErrorLog )

Train an OCR classifier.

trainf_ocr_class_mlp trains the OCR classifier OCRHandle with the training characters stored in the OCR training files given by TrainingFile. The training files must have been created, e.g., using write_ocr_trainf, before calling trainf_ocr_class_mlp.

The remaining parameters have the same meaning as in train_class_mlp and are described in detail with train_class_mlp. A regularization of the OCR classifier and an automatic determination of the regularization parameters (see set_regularization_params_ocr_class_mlp) is taken into account during the training. Furthermore, if a rejection class has been specified using set_rejection_params_ocr_class_mlp, before the actual training the samples for the rejection class are generated.

Please note that training characters that have no corresponding class in the classifier OCRHandle are discarded.

Parameters

• OCRHandle (input_control) .......................... ocr_mlp ～ handle
  Handle of the OCR classifier.
• TrainingFile (input_control) ......................... filename.read(-array) ～ string
  Names of the training files.
  Default value: ‘ocr.trf’
  File extension: .trf, .otr
• MaxIterations (input_control) ........................ integer ～ integer
  Maximum number of iterations of the optimization algorithm.
  Default value: 200
  Suggested values: MaxIterations ∈ {20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300}
• WeightTolerance (input_control) ....................... real ～ real
  Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.
  Default value: 1.0
  Suggested values: WeightTolerance ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
  Restriction: WeightTolerance >= 1.0e-8
• ErrorTolerance (input_control) ........................ real ～ real
  Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.
  Default value: 0.01
  Suggested values: ErrorTolerance ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
  Restriction: ErrorTolerance >= 1.0e-8
• Error (output_control) .................................. real ～ real
  Mean error of the MLP on the training data.
ErrorLog (output_control) .................................................real-array \rightarrow real
Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

Example

* Train an OCR classifier
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, 
    'none', 81, 42, OCRHandle)
trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, ErrorLog)
write_ocr_class_mlp (OCRHandle, 'ocr.omc')

If the parameters are valid, the operator trainf_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

trainf_ocr_class_mlp may return the error 9211 (Matrix is not positive definite) if Preprocessing = 'canonical_variates' is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change Preprocessing to 'normalization'. Another solution can be to add more training samples.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

• OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors
create_ocr_class_mlp, write_ocr_trainf, append_ocr_trainf, write_ocr_trainf_image, set_regularization_params_ocr_class_mlp

train_class_mlp

Module

OCR/OCV

Train an OCR classifier with data from a (protected) training file.

Trainf_ocr_class_mlp_protected trains the OCR classifier OCRHandle with the training data stored in the OCR training files given by TrainingFile. Its functionality corresponds to the functionality of trainf_ocr_class_mlp, with the addition that trainf_ocr_class_mlp_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked
with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator’s functionality see trainf_ocr_class_mlp. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

---

### Parameters

- **OCRHandle** (input_control) ..........................................................ocr_mlp ˜ handle
  Handle of the OCR classifier.

- **TrainingFile** (input_control) .................................................. filename.read(-array) ˜ string
  Names of the training files.

  Default value: 'ocr.trf'

  File extension: .trf, .otr

- **Password** (input_control) ..................................................... string(-array) ˜ string
  Passwords for protected training files.

- **MaxIterations** (input_control) ................................................. integer ˜ integer
  Maximum number of iterations of the optimization algorithm.

  Default value: 200

  Suggested values: MaxIterations ∈ {20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300}

- **WeightTolerance** (input_control) .............................................. real ˜ real
  Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.

  Default value: 1.0

  Suggested values: WeightTolerance ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}

  Restriction: WeightTolerance >= 1.0e-8

- **ErrorTolerance** (input_control) ................................................ real ˜ real
  Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.

  Default value: 0.01

  Suggested values: ErrorTolerance ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}

  Restriction: ErrorTolerance >= 1.0e-8

- **Error** (output_control) ............................................................... real ˜ real
  Mean error of the MLP on the training data.

- **ErrorLog** (output_control) ..................................................... real-array ˜ real
  Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

---

### Result

If the parameters are valid, the operator trainf_ocr_class_mlp_protected returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

trainf_ocr_class_mlp_protected may return the error 9211 (Matrix is not positive definite) if Preprocessing = 'canonical_variates' is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change Preprocessing to 'normalization'. Another solution can be to add more training samples.

---

### Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- **OCRHandle**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.
write_ocr_class_mlp ( : : OCRHandle, FileName : )

Write an OCR classifier to a file.

write_ocr_class_mlp writes the OCR classifier `OCRHandle` to the file given by `FileName`. If a file extension is not specified in `FileName` the default extension `.omc` is appended to `FileName`. `write_ocr_class_mlp` is typically called after the classifier has been trained with `trainf_ocr_class_mlp`. The classifier can be read with `read_ocr_class_mlp`.

**Parameters**

- **OCRHandle** (input_control) Handle of the OCR classifier.
- **FileName** (input_control) File name. File extension: `.omc`

**Result**

If the parameters are valid, the operator `write_ocr_class_mlp` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

---

```plaintext
clear_text_result ( : : TextResultID : )
```

**Clear a text result.**

clear_text_result clears the text result in TextResultID and frees all underlying memory.

Parameters

- **TextResultID** (input_control) : text_result(-array)  handle
  Text result to be cleared.

Result

clear_text_result returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextResultID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

---

```plaintext
create_text_model_reader ( : : Mode, OCRClassifier : TextModel )
```

**Create a text model.**

create_text_model_reader creates a TextModel, which describes the text to be segmented with find_text.
The parameter value of Mode determines which text segmentation approach is used. Possible values are 'auto' and 'manual'. Typically, the parameter Mode should be set to 'auto' because this mode is more stable and requires less configuration effort. Note that in this case, also an OCR classifier must be passed in OCRClassifier. Only if one of the following restrictions apply, Mode must be set to 'manual':

- The segmentation of text which has strong local variations of the polarity is required. For example, due to reflections, engraved text often has strong local variations.
- No suitable OCR classifier is available (see below).

If Mode = 'auto', find_text is able to extract text of arbitrary size. It is possible to restrict the search to characters with specific attributes, see set_text_model_param for details. In particular, if the text to be segmented contains dot printed characters, the text model parameter 'dot_print' must be set to 'true'. Furthermore, an OCR classifier must be passed in OCRClassifier. This OCR classifier must be based on a convolutional neural network (CNN) or a multilayer perceptron (MLP). Moreover, it is strongly recommended to use a CNN based OCR classifier with rejection class or a MLP based classifiers that has been trained with regularization parameters (see set_regularization_params_ocr_class_mlp and provides a rejection class (see set_rejection_params_ocr_class_mlp). A suitable OCR classifier can either be read with read_ocr_class_cnn or read_ocr_class_mlp, or be created with create_ocr_class_mlp. It is also possible to pass a string containing the path to a pretrained OCR classifier or an OCR classifier that has been stored with write_ocr_class_mlp.

To enable text segmentation when Mode = 'manual', reasonable parameters for the text model, including the expected character height and width, must be set using set_text_model_param. In this case, the value of OCRClassifier is ignored.

The parameters of the TextModel can be set and queried with set_text_model_param and get_text_model_param.

Since memory is allocated for the text model during the call of create_text_model_reader and during the following operations, the model should be freed explicitly by the operator clear_text_model as soon as it is no longer used.

--- Parameters ---

- **Mode** (input_control) .................................................. string → string
  The Mode of the text model.
  Default value: 'auto'
  List of values: Mode ∈ {'manual', 'auto'}

- **OCRClassifier** (input_control) ........................................ string → string / integer
  OCR Classifier.
  Default value: 'Universal_Rej.occ'

- **TextModel** (output_control) ........................................ text_model → handle
  New text model.

--- Example ---

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

create_text_model_reader returns the value 2 (H_MSG_TRUE).

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_text_model_param, get_text_model_param, find_text

clear_text_model

Module

OCR/OCV

find_text ( Image : : TextModel : TextResultID )

Find text in an image.

find_text finds text specified by the TextModel in the Image and returns the result in TextResultID. Specific results of TextResultID can be obtained with get_text_result and get_text_object.

The text results in TextResultID differ, depending on how Mode was set when creating the TextModel with create_text_model_reader.

For a text model with Mode = 'auto' find_text extracts and classifies text of arbitrary size within the Image. It is possible to restrict the search to characters with specific attributes, see set_text_model_param for details.

For a text model with Mode = 'manual' reasonable parameters for the text model, including the expected character height and width, need to be set using set_text_model_param. Furthermore, the Image is preprocessed such that character like structures are enhanced. The resulting compensated image can be queried from TextResultID if 'persistence' was set to 'true' in TextModel.

Both the text models with Mode = 'auto' and Mode = 'manual' apply various thresholds to the input image and segment character candidates based on region and gray value features. These candidates are further clustered to lines. Each line is individually completed and tested if it fulfills the constraints of a text line. Text models with Mode set to 'auto' require a text line to consist of at least two characters, whereas text models with Mode set to 'manual' require a text line to consist of at least three characters. In a further step, punctuations and separators are added if the correspondent parameters were set via set_text_model_param. Finally, if TextModel contains 'text_line_structure' entries, the completed line is fitted to these structures.

find_text finds text which is roughly horizontally aligned in Image. text_line_orientation and rotate_image can be used to achieve this alignment.

Since memory is allocated for the text result during the call of find_text and during the following operations, the text result should be freed explicitly by the operator clear_text_result as soon as it is no longer used.

Parameters

• Image (input_object) singlechannelimage ~ object : byte / uint2
  Input image.
• TextModel (input_control) text_model ~ handle
  Text model specifying the text to be segmented.
• TextResultID (output_control) text_result ~ handle
  Result of the segmentation.
Example

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

Result
If the parameters are valid, the operator find_text returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Module
OCR/OCV

get_text_model_param ( : : TextModel,
    GenParamName : GenParamValue )

Query parameters of a text model.

get_text_model_param queries the parameters of TextModel. With the exception of 'ocr_classifier', all valid parameters can be queried. See set_text_model_param for a detailed description of the possible values for GenParamName and GenParamValue.

Parameters

▷ TextModel (input_control) ................................. text_model  \sim handle
Text model.
▷ GenParamName (input_control) ............................ string  \sim string
Parameters to be queried.

Default value: 'min_contrast'

Suggested values: GenParamName ∈ ['add_fragments', 'dot_print', 'dot_print_max_dot_gap',
'dot_print_min_char_gap', 'dot_print_tight_char_spacing', 'eliminate_border_blobs', 'max_char_height',
'max_char_width', 'max_stroke_width', 'min_char_height', 'min_char_width', 'min_contrast',
'min_stroke_width', 'num_classes', 'polarity', 'return_punctuation', 'return_separators', 'return_whole_line',
'separate_touching_chars', 'text_line_separator', 'text_line_structure', 'text_line_structure_0',
'text_line_structure_1', 'text_line_structure_2', 'manual_add_fragments', 'manual_base_line_tolerance',
'manual_char_height', 'manual_char_width', 'manual_eliminate_border_blobs',
'manual_eliminate_horizontal_lines', 'manual_fragment_size_min', 'manual_is_dotprint',
'manual_is_imprinted', 'manual_max_line_num', 'manual_persistence', 'manual_polarity',
'manual_return_punctuation', 'manual_return_separators', 'manual_stroke_width',
'manual_text_line_structure', 'manual_text_line_structure_0', 'manual_text_line_structure_1',
'manual_text_line_structure_2', 'manual_uppercase_only']

HALCON 20.11.0.0
If the input parameters are set correctly, the operator \texttt{get\_text\_model\_param} returns the value 2 (H\_MSG\_TRUE). Otherwise, an exception will be raised.

**Execution Information**

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

\texttt{Module}

\texttt{OCR/OCV}

\begin{flushleft}
\textbf{get\_text\_object} ( \ :	exttt{ Characters} : \texttt{ TextResultID}, \texttt{ ResultName} : )
\end{flushleft}

Query an iconic value of a text segmentation result.

\texttt{get\_text\_object} queries the iconic result \texttt{ResultName} of \texttt{TextResultID} returned by \texttt{find\_text}. The possible parameter values for \texttt{ResultName} differ, depending on the text model used within the text segmentation process of \texttt{find\_text}.

In the following, first the possible parameter values for text models with \texttt{Mode} = \texttt{’auto’} are listed, and then those for text models with \texttt{Mode} = \texttt{’manual’}.

The following results can be queried:

- **Result objects for text segmentation with text models with Mode = \texttt{’auto’}**
  
  For each polarity, the text lines are independently sorted from top to bottom and left to right. The character within the text lines are sorted from left to right.
  
  \texttt{’all\_lines’}: Returns all characters in all segmented text lines.
  
  [\texttt{’line’, LineIndex}]: Returns all characters within the text line specified by \texttt{LineIndex}. For example, [\texttt{’line’, 0}] returns the first line.
  
  [\texttt{’element’, Index}]: Returns the character at position \texttt{Index}. For example, [\texttt{’element’, 0}] returns the first character.

- **Result objects for text segmentation with text models with Mode = \texttt{’manual’}**
  
  \texttt{’manual\_all\_lines’}: Returns all characters in all segmented text lines. The text lines are sorted from top to bottom and left to right.
  
  [\texttt{’manual\_line’, Index}]: Returns all characters within the text line specified by \texttt{Index} (e.g. [\texttt{’manual\_line’, 0}] to return the first line). The characters within the text line are sorted from left to right.

If \texttt{’manual\_persistence’} was activated for the text model used to create \texttt{TextResultID}, the following additional value can be queried:

\texttt{’manual\_compensated\_image’}: the enhanced image used for segmentation.

**Parameters**

\begin{itemize}
  \item \textbf{Characters} (output\_object) \texttt{object(-array)} \texttt{~} \texttt{object} \texttt{Returned result.}
  \item \textbf{TextResultID} (input\_control) \texttt{\texttt{text\_result} \texttt{~} \texttt{handle} \texttt{Text result.}
  \item \textbf{ResultName} (input\_control) \texttt{\texttt{string(-array)} \texttt{~} \texttt{string / integer} \texttt{Name of the result to be returned.}
  \end{itemize}

\textbf{Default value:} \texttt{’all\_lines’}

\textbf{List of values:} \texttt{ResultName \in \{’all\_lines’, ’element’, ’line’, ’manual\_all\_lines’, ’manual\_line’, ’manual\_compensated\_image’ \}}
21.6. SEGMENTATION

Example

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

Result

If the parameters are valid, the operator get_text_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Processed without parallelization.

get_text_result

Module

Foundation

get_text_result ( : : TextResultID, ResultName : ResultValue )

Query a control value of a text segmentation result.

get_text_result queries the control result ResultName of TextResultID returned by find_text.
The possible parameter values for ResultName differ, depending on the text model used within the text segmentation process of find_text.

In the following, first the possible parameter values for text models with Mode = 'auto' are listed, and then those for text models with Mode = 'manual'.

The following results can be queried:

• Results for text segmentation with text models with Mode = 'auto'
  For each polarity, the text lines are independently sorted from top to bottom and left to right. The character within the text lines are sorted from left to right.
  'num_lines': Number of lines found.
  'num_classes': Number of best classes stored for each character. Depending on the number of classes of the used classifier this value might be smaller than the one set in the text model, see set_text_model_param.
  'class': Classification results of all segmented characters with the OCR classifier contained in the corresponding text model. Note that if the classifier was trained with rejection class, get_text_result returns the second best result for characters that are classified as rejection class.
  ['class', n]: Similar to 'class', except that the class with the (n+1)-highest confidence is returned. For example, ['class', 0] returns for each character the class with the highest confidence. Moreover, in contrast to 'class', the rejection class can be returned if the classifier contained in the corresponding text model was trained with rejection class.
Classification results of the characters within the text line specified by LineIndex with the OCR classifier contained in the corresponding text model. For example, ['class_line', 0] returns the character classes within the first text line. Note that if the classifier was trained with rejection class, get_text_result returns the second best result for characters that are classified as rejection class.

['class_line', LineIndex, n]: Similar to ['class_line', LineIndex], except that the classes with the (n+1)-highest confidences are returned. For example, ['class_line', LineIndex, 0] returns for each character in the text line specified by LineIndex the class with the highest confidence. Moreover, in contrast to ['class_line', LineIndex], the rejection class can be returned if the classifier contained in the corresponding text model was trained with rejection class.

['class_element', Index]: Classification result of the character at position Index with the OCR classifier contained in the corresponding text model. For example ['class_element', 0] returns the 'num_classes' best classes (sorted by confidence) of the first character.

'confidence': Returns the confidences of the classes for all segmented characters, see 'class'.

['confidence', n]: Returns the confidences of the classes with the (n+1)-highest confidence, see ['class', n].

['confidence_line', LineIndex]: Returns the confidences of the classes of all characters within the text line specified by LineIndex, see ['class_line', LineIndex].

['confidence_line', LineIndex, n]: Returns the confidences of the classes with the (n+1)-highest confidence for all characters within the text line specified by LineIndex, see ['class_line', LineIndex, n].

['confidence_element', Index]: Returns the confidences corresponding to the classes of the character at position Index, see ['class_element', Index].

'polarity': Returns the polarity of all segmented characters.

['polarity_line', LineIndex]: Returns the polarity of the characters in the segmented text line specified by LineIndex. For example, ['polarity_line', 0] returns the polarity within the first text line.

['polarity_element', Index]: Returns the polarity of the character at the position Index. For example ['polarity_element', 0] returns the polarity of the first character.

• Results for text segmentation with text models with Mode = 'manual'

'manual_num_lines': Number of lines found.

If 'manual_persistence' was activated for the text model used to create TextResultID, the following additional value can be queried:

'manual_thresholds': The thresholds used for segmentation.

Parameters

> TextResultID (input_control) ......................................................... text_result → handle
> ResultName (input_control) ......................................................... string(-array) → string / integer
  Name of the result to be returned.

  Default value: 'class'

  List of values: ResultName ∈ {'class', 'class_element', 'class_line', 'confidence', 'confidence_element', 'confidence_line', 'polarity', 'polarity_element', 'polarity_line', 'num_classes', 'num_lines', 'manual_num_lines', 'manual_thresholds'}

> ResultValue (output_control) ...................................................... string(-array) → integer / real / string
  Value of ResultName.

Example

read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
  * Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
  * Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)

Result

If the parameters are valid, the operator get_text_result returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.
Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

get_text_object

Module

Foundation

**segment_characters** ( Region, Image : ImageForeground,
RegionForeground : Method, EliminateLines, DotPrint, StrokeWidth,
CharWidth, CharHeight, ThresholdOffset, Contrast : UsedThreshold )

Segments characters in a given region of an image.

This operator is used to segment characters in a given Region of an Image. The Region is only used to reduce the working area. The segmented characters are returned in RegionForeground.

Two different methods to detect the characters are supplied. All segmentation methods assume that the text is darker than the background. If this is not the case, please invert the image with invert_image.

The parameter Method determines the algorithm for text segmentation. The possible values are

- **'local_contrast_best'** This method extracts text that differ locally from the background. Therefore, it is suited for images with inhomogeneous illumination. The enhancement of the text borders, leads to a more accurate determination of the outline of the text. Which is especially useful if the background is highly textured. The parameter Contrast defines the minimum contrast, i.e., the minimum gray value difference between symbols and background.

- **'local_auto_shape'** The minimum contrast is estimated automatically such that the number of very small regions is reduced. This method is especially suitable for noisy images. The parameter ThresholdOffset can be used to adjust the threshold. Let \( g(x,y) \) be the gray value at position \((x,y)\) in the input Image. The threshold condition is determined by:

\[
g(x,y) \leq \text{UsedThreshold} + \text{ThresholdOffset}.
\]

Select EliminateLines if the extraction of characters is disturbed by lines that are horizontal or vertical with respect to the lines of text and set its value to 'true'. The elimination is influenced by the maximum of CharWidth and the maximum of CharHeight. For further information see the description of these parameters.

DotPrint: Should be set to 'true' if dot prints should be read, else to 'false'.

StrokeWidth: Specifies the stroke width of the text. It is used to calculate internally used mask sizes to determine the characters. This mask sizes are also influenced through the parameters DotPrint, the average CharWidth, and the average CharHeight.

CharWidth: This can be a tuple with up to three values. The first value is the average width of a character. The second is the minimum width of a character and the third is the maximum width of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on the average CharWidth. The same is the case if the maximum is not set. Some examples:

- [10] sets the average character width to 10, the minimum and maximum are calculated by the operator.
- [10,-1,20] sets the average character width to 10, the minimum value is calculated by the system, and the maximum is set to 20.
- [10,5,20] sets the average character width to 10, the minimum to 5, and the maximum to 20.

CharHeight: This can be a tuple with up to three values. The first value is the average height of a character. The second is the minimum height of a character and the third is the maximum height of a character. If the minimum is
not set or equal -1, the operator automatically sets these value depending on the average \text{CharHeight}. The same is the case if the maximum is not set. Some examples:

[10] sets the average character height to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character height to 10, the minimum value is calculated by the system, and the maximum is set to 20.

[10,5,20] this sets the average character height to 10, the minimum to 5, and the maximum to 20.

\textbf{ThresholdOffset}: This parameter can be used to adjust the threshold, which is used when the segmentation method \textit{"local_auto_shape"} is chosen.

\textbf{Contrast}: Defines the minimum contrast between the text and the background. This parameter is used if the segmentation method \textit{"local_contrast_best"} is selected.

\textbf{UsedThreshold}: After the execution, this parameter returns the threshold used to segment the characters.

\textbf{ImageForeground} returns the image that was internally used for the segmentation.

\begin{verbatim}
Parameters

\begin{itemize}
  \item \textbf{Region} (input_object) \rightarrow \text{region-array} \sim \text{object}
    Area in the image where the text lines are located.
  \item \textbf{Image} (input_object) \rightarrow \text{singlechannelimage} \sim \text{object}: \text{byte} / \text{uint2}
    Input image.
  \item \textbf{ImageForeground} (output_object) \rightarrow \text{image-array} \sim \text{object}: \text{byte} / \text{uint2}
    Image used for the segmentation.
  \item \textbf{RegionForeground} (output_object) \rightarrow \text{singlechannelregion-array} \sim \text{object}
    Region of characters.
  \item \textbf{Method} (input_control) \rightarrow \text{string}
    Method to segment the characters.
    \textbf{Default value}: \textit{"local_auto_shape"}
    \textbf{List of values}: \text{Method} \in \{ \textit{"local_contrast_best"}, \textit{"local_auto_shape"} \}
  \item \textbf{EliminateLines} (input_control) \rightarrow \text{string}
    Eliminate horizontal and vertical lines?
    \textbf{Default value}: \textit{false}
    \textbf{List of values}: \text{EliminateLines} \in \{ \textit{true}, \textit{false} \}
  \item \textbf{DotPrint} (input_control) \rightarrow \text{string}
    Should dot print characters be detected?
    \textbf{Default value}: \textit{false}
    \textbf{List of values}: \text{DotPrint} \in \{ \textit{true}, \textit{false} \}
  \item \textbf{StrokeWidth} (input_control) \rightarrow \text{string}
    Stroke width of a character.
    \textbf{Default value}: \textit{medium}
    \textbf{List of values}: \text{StrokeWidth} \in \{ \textit{ultra_light}, \textit{light}, \textit{medium}, \textit{bold} \}
  \item \textbf{CharWidth} (input_control) \rightarrow \text{integer-array} \sim \text{integer}
    Width of a character.
    \textbf{Default value}: 25
    \textbf{Typical range of values}: 1 \leq \text{CharWidth}
    \textbf{Restriction}: \text{CharWidth} \geq 1
  \item \textbf{CharHeight} (input_control) \rightarrow \text{integer-array} \sim \text{integer}
    Height of a character.
    \textbf{Default value}: 25
    \textbf{Typical range of values}: 1 \leq \text{CharHeight}
    \textbf{Restriction}: \text{CharHeight} \geq 1
  \item \textbf{ThresholdOffset} (input_control) \rightarrow \text{integer}
    Value to adjust the segmentation.
    \textbf{Default value}: 0
  \item \textbf{Contrast} (input_control) \rightarrow \text{integer}
    Minimum gray value difference between text and background.
    \textbf{Default value}: 10
    \textbf{Typical range of values}: 1 \leq \text{Contrast}
    \textbf{Restriction}: \text{Contrast} \geq 1
\end{itemize}
\end{verbatim}
21.6. SEGMENTATION

- **UsedThreshold** (output_control) ........................................integer(-array) ~ integer
  
  Threshold used to segment the characters.

  --- Example ---

  for Index := 1 to 5 by 1
    read_image (Image, 'dot_print_rotated/dot_print_rotated_' + Index$'02d')
    text_line_orientation (Image, Image, 50, rad(-30), rad(30), OrientationAngle)
    rotate_image (Image, ImageRotate, deg(-OrientationAngle), 'constant')
    segment_characters (ImageRotate, ImageRotate, ImageForeground, \  
         RegionForeground, 'local_auto_shape', 'false', 'false', 'medium', \  
         25, 25, 0, 10, UsedThreshold)
  endfor

  --- Result ---

  If the input parameters are set correctly, the operator segment_characters returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

  --- Execution Information ---

  - Multithreading type: reentrant (runs in parallel with non-exclusive operators).
  - Multithreading scope: global (may be called from any thread).
  - Automatically parallelized on tuple level.

  --- Possible Predecessors ---

  --- Module ---

  Foundation

| select_characters | ( Region : RegionCharacters : DotPrint, StrokeWidth, CharWidth, CharHeight, Punctuation, DiacriticMarks, PartitionMethod, PartitionLines, FragmentDistance, ConnectFragments, ClutterSizeMax, StopAfter : ) |

Selects characters from a given region.

**select_characters** selects from a given Region the areas which might be characters and returns them in RegionCharacters. This is done by using features like StrokeWidth, DotPrint, the size of the characters and some more. The given Region should be united, else every Region is processed separately. Thus do not call connection before calling select_characters, because then fragments or dots would not be connected to a character. If you have more than one region with text, you can of course handle them without merging them. The Region for select_characters typically comes from segment_characters but also any other segmentation operators can be used.

The process of the selection can be partitioned into four parts. All steps are influenced by the parameters StrokeWidth, CharHeight, and CharWidth. If you loose small objects like dots, adapt the minimum CharWidth and the minimum CharHeight. But some parameters affect the result of a certain step in particular. A closer description follows below. With the parameter StopAfter you can terminate after a specified step.

In the first step, 'step1_select_candidates', CharWidth and the CharHeight are used to select the candidates. The result of this step is also affected by ClutterSizeMax.

In the next step, 'step2_partition_characters', the parameter PartitionMethod and the parameter PartitionLines influence the result.

HALCON 20.11.0.0
Step three, ‘step3_connect_fragments’, uses the parameters ConnectFragments and DotPrint. If dot-printed characters have to be detected and some dots are not connected to the character, there are two ways to overcome this problem: You can increase the FragmentDistance and/or decrease the StrokeWidth.

In the last step, ‘step4_select_characters’, the result is affected by the parameters DiacriticMarks and Punctuation.

DotPrint: Should be set to ‘true’ if dot prints should be read, else to ‘false’.

StrokeWidth: Specifies the stroke width of the text. It is used to calculate internally used mask sizes to determine the characters. This mask sizes are also influenced through the parameters DotPrint, the average CharWidth, and the average CharHeight.

CharWidth: This can be a tuple with up to three values. The first value is the average width of a character. The second is the minimum width of a character and the third is the maximum width of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on average CharWidth. The same is the case if the maximum is not set. Some examples:
[10] sets the average character width to 10, the minimum and maximum are calculated by the operator.
[10,-1,20] sets the average character width to 10, the minimum value is calculated by the system, and the maximum is set to 20.
[10,5,20] sets the average character width to 10, the minimum to 5, and the maximum to 20.

CharHeight: This can be a tuple with up to three values. The first value is the average height of a character. The second is the minimum height of a character and the third is the maximum height of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on average CharHeight. The same is the case if the maximum is not set. Some examples:
[10] sets the average character height to 10, the minimum and maximum are calculated by the operator.
[10,-1,20] sets the average character height to 10 the minimum value is calculated by the system and the maximum is set to 20.
[10,5,20] this sets the average character height to 10, the minimum to 5 and the maximum to 20.

Punctuation: Set this parameter to ‘true’ if the operator also has to detect punctuation marks (e.g. .,:’’’), otherwise they will be suppressed.

DiacriticMarks: Set this parameter to ‘true’ if the text in your application contains diacritic marks (e.g. â,é,ö), or to ‘false’ to suppress them.

PartitionMethod: If neighboring characters are printed close to each other, they may be partly merged. With this parameter you can specify the method to partition such characters. The possible values are ‘none’, which means no partitioning is performed. ‘fixed_width’ means that the partitioning assumes a constant character width. If the width of the extracted region is well above the average CharWidth, the region is split into parts that have the given average CharWidth. The partitioning starts at the left border of the region. ‘variable_width’ means that the characters are partitioned at the position where they have the thinnest connection. This method can be selected for characters that are printed with a variable-width font or if many consecutive characters are extracted as one symbol. It could be helpful to call text_line_slant and/or use text_line_orientation before calling select_characters.

PartitionLines: If some text lines or some characters of different text lines are connected, set this parameter to ‘true’.

FragmentDistance: This parameter influences the connection of character fragments. If too much is connected, set the parameter to ‘narrow’ or ‘medium’. In the case that more fragments should be connected, set the parameter to ‘medium’ or ‘wide’. The connection is also influenced by the maximum of CharWidth and CharHeight. See also ConnectFragments.

ConnectFragments: Set this parameter to ‘true’ if the extracted symbols are fragmented, i.e., if a symbol is not extracted as one region but broken up into several parts. See also FragmentDistance and StopAfter in the step ‘step3_connect_fragments’.

ClutterSizeMax: If the extracted characters contain clutter, i.e., small regions near the actual symbols, increase this value. If parts of the symbols are missing, decrease this value.

StopAfter: Use this parameter in the case the operator does not produce the desired results. By modifying this value the operator stops after the execution of the selected step and provides the corresponding results. To end on completion, set StopAfter to ‘completion’.
21.6. SEGMENTATION

Parameters

- **Region** (input_object) → object
  Region of text lines in which to select the characters.

- **RegionCharacters** (output_object) → object
  Selected characters.

- **DotPrint** (input_control) → string
  Should dot print characters be detected?
  Default value: 'false'
  List of values: DotPrint ∈ {'true', 'false'}

- **StrokeWidth** (input_control) → string
  Stroke width of a character.
  Default value: 'medium'
  List of values: StrokeWidth ∈ {'ultra_light', 'light', 'medium', 'bold'}

- **CharWidth** (input_control) → integer-array
  Width of a character.
  Default value: 25
  Typical range of values: 1 ≤ CharWidth
  Restriction: CharWidth >= 1

- **CharHeight** (input_control) → integer-array
  Height of a character.
  Default value: 25
  Typical range of values: 1 ≤ CharHeight
  Restriction: CharHeight >= 1

- **Punctuation** (input_control) → string
  Add punctuation?
  Default value: 'false'
  List of values: Punctuation ∈ {'true', 'false'}

- **DiacriticMarks** (input_control) → string
  Exist diacritic marks?
  Default value: 'false'
  List of values: DiacriticMarks ∈ {'true', 'false'}

- **PartitionMethod** (input_control) → string
  Method to partition neighbored characters.
  Default value: 'none'
  List of values: PartitionMethod ∈ {'none', 'fixed_width', 'variable_width'}

- **PartitionLines** (input_control) → string
  Should lines be partitioned?
  Default value: 'false'
  List of values: PartitionLines ∈ {'true', 'false'}

- **FragmentDistance** (input_control) → string
  Distance of fragments.
  Default value: 'medium'
  List of values: FragmentDistance ∈ {'narrow', 'medium', 'wide'}

- **ConnectFragments** (input_control) → string
  Connect fragments?
  Default value: 'false'
  List of values: ConnectFragments ∈ {'true', 'false'}

- **ClutterSizeMax** (input_control) → integer
  Maximum size of clutter.
  Default value: 0
  Typical range of values: 0 ≤ ClutterSizeMax
  Restriction: 0 < ClutterSizeMax

- **StopAfter** (input_control) → string
  Stop execution after this step.
  Default value: 'completion'
  List of values: StopAfter ∈ {'step1_select_candidates', 'step2_partition_characters', 'step3_connect_fragments', 'step4_select_characters', 'completion'}
for Index := 1 to 5 by 1
    read_image (Image, 'dot_print_rotated/dot_print_rotated_"+Index$'02d')
    text_line_orientation (Image, Image, 50, rad(-30), rad(30), OrientationAngle)
    rotate_image (Image, ImageRotate, deg(-OrientationAngle), 'constant')
    segment_characters (ImageRotate, ImageRotate, ImageForeground, 
        RegionForeground, 'local_auto_shape', 'false', 'false', 'medium', 
        25, 25, 0, 10, UsedThreshold)
    select_characters (RegionForeground, RegionCharacters, 'true', 'ultra_light', 
        [60,1,100], [60,1,100], 'false', 'false', 'none', 'true', 'wide', 'true', 0, 
        'completion')
endfor

If the input parameters are set correctly, the operator select_characters returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

• Multithreading type: reentrant (runs in parallel with non-exclusive operators).
• Multithreading scope: global (may be called from any thread).
• Automatically parallelized on tuple level.

Possible Predecessors
segment_characters, text_line_slant

Possible Successors

Module

set_text_model_param ( : : TextModel, GenParamName, GenParamValue : )

Set parameters of a text model.

set_text_model_param sets parameters of a text model. The list of allowed parameter values for GenParamName differs, depending on which Mode was set when creating the text model with create_text_model_reader. In the following, first the parameter values for text models with Mode = 'auto' are listed, and then those for text models with Mode = 'manual'.

The name and value of a parameter must be given in GenParamName and GenParamValue. The following values are possible:

• Parameters of text models with Mode = 'auto'
  – Segmentation behavior
    'min_contrast': The minimal contrast the characters have to their surrounding background.
      List of values: integer or float value between 1 and 255 for byte images and between 1 and 65.535 for uint2 images
      Default value: 15
    'polarity': 'dark_on_light' if the text to be segmented is darker than its background, 'light_on_dark'
      if the text to be segmented is lighter than its background, and 'both' if both kinds of text are to be segmented.
      List of values: 'dark_on_light', 'light_on_dark', 'both'
      Default value: 'both'
‘eliminate_border_blobs’: ‘true’ if regions that are touching the border of the image domain should be discarded, otherwise ‘false’.
List of values: ‘true’, ‘false’
Default value: ‘false’

‘add_fragments’: ‘true’ if fragments, such as the dot on the ‘i’, should be added to the segmented characters, otherwise ‘false’. Be aware, that this can cause noise to be added to the segmented characters.
List of values: ‘true’, ‘false’
Default value: ‘true’

‘separate_touching_chars’: Controls the handling of pairs or small groups of neighboring characters that are segmented as one single region. When selecting ‘standard’ or ‘enhanced’, such regions are detected and separated into two or more single characters. While the ‘enhanced’ method yields more accurate results, the ‘standard’ method is less complex and thus faster. If ‘separate_touching_chars’ is set to ‘false’, no separation of touching characters is performed.
Remark: If ‘enhanced’ is selected, the file find_text_support.hotc from the ocr subdirectory of the root directory of the HALCON installation is needed. It is also possible to place this file in the current working directory.
List of values: ‘false’, ‘standard’, ‘enhanced’
Default value: ‘standard’

– Character size

‘min_char_height’: The minimal height of the characters in pixel. If text of arbitrary height is to be segmented, ‘auto’ may be passed. Note that ‘min_char_height’ refers to characters only. The height of punctuation marks or separators is not restricted by ‘min_char_height’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

‘max_char_height’: The maximal height of the characters in pixel. If text of arbitrary height is to be segmented, ‘auto’ may be passed. Note that ‘max_char_height’ refers to characters only. The height of punctuation marks or separators is not restricted by ‘max_char_height’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

‘min_char_width’: The minimal width of the characters in pixel. If text of arbitrary width is to be segmented, ‘auto’ may be passed. Note that ‘min_char_width’ refers to characters only. The width of punctuation marks or separators is not restricted by ‘min_char_width’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

‘max_char_width’: The maximal width of the characters in pixel. If text of arbitrary width is to be segmented, ‘auto’ may be passed. Note that ‘max_char_width’ refers to characters only. The width of punctuation marks or separators is not restricted by ‘max_char_width’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

‘min_stroke_width’: The minimal stroke width of the characters in pixel. If the minimal stroke width is to be estimated within the text segmentation process automatically, ‘auto’ may be passed. Note that ‘min_stroke_width’ refers to characters only. The stroke width of punctuation marks or separators is not restricted by ‘min_stroke_width’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

‘max_stroke_width’: The maximal stroke width of the characters in pixel. If the maximal stroke width is to be estimated within the text segmentation process automatically, ‘auto’ may be passed. Note that ‘max_stroke_width’ refers to characters only. The stroke width of punctuation marks or separators is not restricted by ‘max_stroke_width’.
List of values: integer or float value greater or equal to 1
Default value: ‘auto’

– Special characters

‘return_punctuation’: ‘true’ if small punctuation marks that lie close to the base line of the corresponding text line (e.g. dots or commas) are to be returned. ‘false’ if no such punctuations should be returned.
List of values: ‘true’, ‘false’
Default value: ‘true’
'return_separators': 'true' if separators such as a minus or the equality sign should be returned as well. 'false' if no separators should be returned.

List of values: 'true', 'false'
Default value: 'true'

Handling of dot prints

'dot_print': 'true' if the text to be segmented contains dot printed characters, otherwise 'false'.

List of values: 'true', 'false'
Default value: 'false'

dot_print_tight_char_spacing': 'true' if the gap between adjacent characters is smaller than the largest gap between two dots within a single character, otherwise 'false'. If 'dot_print' is set to 'false' this parameter does not have any effect. In cases where the minimal gap size between characters is exactly known, 'dot_print_min_char_gap' can be set instead. In this case the value of 'dot_print_tight_char_spacing' is ignored.

List of values: 'true', 'false'
Default value: 'false'

dot_print_min_char_gap': The minimal gap size between two characters in pixel. This parameter can be used to improve the text result in cases where the minimal gap size between characters is smaller than the maximal gap size between dots within characters. If the minimal character gap size is not known or is bigger than the maximal dot gap size, 'auto' may be passed. If 'dot_print' is set to 'false' this parameter does not have any effect. In cases where the minimal gap size between characters is not known but the characters are printed close to each other, 'dot_print_tight_char_spacing' might be used instead.

Here, the minimal gap size between characters is 8 pixel.

List of values: integer or float value greater or equal to 0
Default value: 'auto'

dot_print_max_dot_gap': The maximal gap size between two dots within a character in pixel. If arbitrary dot printed characters are to be segmented, 'auto' may be passed. If 'dot_print' is set to 'false' this parameter does not have any effect. In cases where the maximal dot gap size is larger than or equal to the minimal gap size between characters, 'dot_print_tight_char_spacing' or 'dot_print_min_char_gap' should be set accordingly. Setting 'dot_print_max_dot_gap' can reduce the runtime of find_text significantly.

Here, the maximal gap size between dots is 3 pixel.

List of values: integer or float value greater or equal to 1
Default value: 'auto'
21.6. SEGMENTATION

Line structures
'text_line_structure': To simplify the search for specific structures (e.g. dates or serial numbers) within the segmented text, it is possible to define text line structures. For each text line the distances between the characters are calculated, and based on these distances, the text line is divided into text blocks. Short characters such as '.', '_' and '-' are ignored in this process and treated as spaces. Furthermore, it is possible to define user specific separators which are also ignored. See the description of 'text_line_separators' for details. It is then tested if any of the user defined text line structures fit the resulting text blocks.

For example, if the text to be found is a date with two characters for month, day, and year the structure would be '2 2 2'. If the year may consist of two or four characters, the structure would be '2 2 2-4', indicating that the last character block consists of two to four characters. It is possible to provide more than one structure to match by appending an index to the parameter name, e.g. 'text_line_structure_0', 'text_line_structure_1'. If 'text_line_structure' is set to an empty string '', the text to be found may have any structure.

Please observe, that every text line structure which is found, is saved as a unique text line within the text result. Hence, when calling get_text_object, a 'line' then refers to a valid text line structure. If the whole text line containing the text line structure is to be returned instead, it is possible to set 'return_whole_line' accordingly.

Default value: ''

'text_line_separators': A string containing the list of characters which are to be ignored in the process of finding text line structures, see 'text_line_structure' for further details. Please note, user specific separators need to be valid characters within the used OCR classifier. For example, if ':' and '\' are to be ignored, ':' should be passed. Please observe, that '\' escapes any special symbol to treat it as a literal, and hence '\' needs to be passed to use '\' as a separator.

List of values: '/', ':', '\:', '\:', '\:', '\:', '\:', '

Default value: ''

'return_whole_line': 'false' if only the segmented text line structures are to be returned as text lines. 'true' if each whole text line containing a text line structure is to be returned in text lines.

List of values: 'true', 'false'

Default value: 'false'

OCR classifier

'ocr_classifier': The OCR classifier used within find_text for text segmentation and classification. An initial classifier is set when the text model is created. See create_text_model_reader for more information about the required OCR Classifier.

'num_classes': The number of best classes to be stored for each character. (E.g. if 'num_classes' is set to 2, find_text returns the classification results with the highest and second highest confidence). If 'num_classes' exceeds the number of classes of the classifier stored in the text model, 'num_classes' is decreased accordingly. The actual number of classes can be queried by get_text_result. For classifiers with rejection class, 'num_classes' should be at least 2 in order to be able to use the second best result if a character is classified as rejection class.

List of values: integer greater than or equal to 1.

Default value: 2

• Parameters of text models with Mode = 'manual'

'manual_char_height': Height of the characters in pixel. Refers to an uppercase character. Default value: 30px

'manual_char_width': Width of the characters in pixel. Refers to an uppercase character. Default value: 20px

'manual_stroke_width': Stroke width of the characters in pixel. Default value: 4.0px

'manual_base_line_tolerance': Maximum base line deviation of the characters (in percent of 'manual_char_height'). Default value: 0.15

'manual_polarity': 'dark_on_light' if the text to be segmented is darker than its background, otherwise 'light_on_dark'. Default value: 'dark_on_light'

'manual_uppercase_only': 'true' if the text to be segmented contains uppercase characters or numbers only, otherwise 'false'. Default value: 'false'

'manual_is_dotprint': 'true' if the text to be segmented is a dotprint, otherwise 'false'. Default value: 'false'

'manual_is_imprinted': 'true' if the text to be segmented suffers of local changes of polarity due to reflections, otherwise 'false'. Default value: 'false'
